Apart from commercial crises, probably the most potent effect on price levels and the condition of trade is produced, not by the strife which is supposed to exist of necessity between labour and capital, but by the constant struggle of holders of capital with each other in the quest of remunerative employment for wealth, mainly created within recent times by machine production. This has caused the invasion of every department of industry by groups of persons without skill or experience, and possessed only of money or credit, or, it may be, of aristocratic lineage. The competition of these with each other frequently results in the redistribution of their wealth among the community, in the form of the increased wages and reduced prices, with which we are familiar, and against which we are sometimes disposed to rebel. The ever-extending use of labour-saving devices in workshops and factories, whose owners have command of large capital, gives some plausibility to the contention that machinery is much to blame for trade depression, especially if the displacement of labour is not at once, and obviously, made up for by the cheapening of products, and greater facilities for transport stimulating demand; but wider views would probably disclose that the balance is speedily restored. It is interesting, and indeed necessary, for us to inquire what becomes, after all, of the displaced labour, and if there is any visible limit to the substitution of machinery for handicraft. If we avail ourselves of the examinations of the census returns by Messrs. Booth, Hobson, and Marshall, we shall find, for example, that while the output of textile goods has enormously increased, the proportion of labour employed in their production has continuously diminished. Again, while rural population has declined but little, the number of persons engaged in agricultural labour has largely declined, and this falling-off began long before the comparatively recent fall in rents, and what is recognised as the decay of agriculture in this country. The additions to our working population have, therefore, not been absorbed in due proportion by these two great departments of industry, but are to be found, according to the authorities named above, engaged in shop-keeping, commercial pursuits, in the work of transport, and the industries subsidiary thereto. Among these, one of the most important is shipbuilding, which afforded employment to 40 per cent. more persons in 1891 than in 1881. Those engaged in the making of machines, tools, and instruments during the decade increased 28 per cent. These have been the most progressive of our industries, and indicate the extraordinary growth of transport and machine making as modern outlets for labour. The extension of railways has not prevented the increase of traffic by road, as the employment of labour in the making and repairing of roads, in the conducting of road traffic, in the building of carriages and wagons, and the making of harness, shows considerable increase. Coal miners have increased in numbers—35 per cent. in ten years—but the output of coal is only 20 per cent. greater, indicating the serious interruptions to which this industry seems peculiarly liable. Notable increase is also shown by the professions, clerical, legal, and medical—indeed, on the authority of the Chancellor of the Exchequer, the incomes of physicians and lawyers together exceed the whole of the profits of the cotton and coal industries. There is great increase of the teaching guild, and of the numbers of painters, actors, and musicians. These have been set free, by the action of machinery, from the necessity of manual labour. Machinery, therefore, indirectly encourages the study of theology and science, the cultivation of the fine arts, and the graceful acquirements of those who minister to our recreation. Even the army, navy, and police grow more quickly in numbers than the population as a whole. Our protection is thus made more adequate by the art of the mechanical engineer. And in spite of depression, the manufacture of luxuries rapidly increases. No one denies the function of machinery in the production of wealth, and it only remains to establish that the production and accumulation of wealth is not injurious, but, on the whole, beneficent, as by no possibility can its consumption be, in the long run, withheld from the many; and to realise that attacks on the capitalist, in so far as they discourage the amassing of riches, are more likely to lead to the distress than the benefit of the poor, and to the decrease of that purchasing power which is the spring of commerce.

In whatever way we may sum up our estimate of the net effect of labour-saving machinery, there can be no doubt whatever that its use is, in itself, a constant stimulus to invention, and that it will continually increase in efficiency, and in encroachment on the province of manual labour. Machinery, to use a slang expression, has come to stay, and machine tending is more and more taking the place of skilled handicraft in our staple industries. The collectivist, as he calls himself, jealous of the success of the successful, advocates, in the interests of the many, the national control of all means of production, distribution, and exchange, or the assumption by the State of the duties of the landlord, the factory owner, the railroad and steamship manager, and the banker. The old-fashioned virtues of industry, thrift, and self-reliance, are to be discarded, but it is not quite clear what is to take their place. The prayer of the collectivist, or socialist—as has been aptly said—contains but two petitions: "Give us our daily bread, and forgive us our debts." I venture to say that the granting of his prayer, and the adoption of his methods, would bring about a depression of trade such as has never been experienced, or even imagined; and it is hard to say in how great a measure the confused mutterings of this sort have been the cause of the diversion of our capital abroad, with the result of inducing a feverish and unhealthy state of trade for a time, a subsequent collapse, and irrecoverable loss. I deem it rational to hold that the lot of man has been made more tolerable by machinery, his toil lightened, and his opportunities for intellectual and artistic culture increased; but the best of results will not be reaped from its use unless wage-earners of all nationalities will make common cause with capitalists in procuring the withdrawal of all restrictions on the exchange of products and services for money or other considerations, in abolishing tariffs which hinder the production of goods in favourable localities, that they may be fabricated in places which are disadvantageous, and, having repressed their own tendencies to wasteful expenditure, in enforcing a like virtue on their governments, imperial and municipal. The escape from industrial depression lies in the removal of all obstacles to the steady increase of consuming power, in the setting of rational bounds to militarism, in the mobility of capital and labour—that co-relation between production and consumption may be more readily maintained, and by no means in the return to universal manual labour, or in attempts to realise formless dreams of a government assuming the functions of the universal provider. It is possible that the benefits, in the form of power to consume, which might reasonably be expected from the use of machinery, and the consequent creation of wealth, have not been so largely or so widely realised, or so wisely availed of as a generous sympathy with mankind might desire; but this is not admitting that machinery is injurious, or that destitution is the consequence of opulence, because they exist side by side. Impatience at the slowness with which the standard of living rises need not amount to denial that it rises at all. The conditions of labour in the early factories were sufficiently wretched, but they were an improvement on those of the home industries they superseded. Present conditions are immeasurably superior; but it is not generally held that finality in this respect has been reached, neither is it likely that the limit of consumption has been reached, or nearly approached, because, for the time, production appears to have overtaken, and, indeed, to have outstripped it, in the kind of goods hitherto in general demand. If Governments will refrain from what is known by the engaging name of "constructive legislation," and adhere to their primary duty of maintaining security for person and property, private enterprise, on which the State itself depends, may safely be trusted with the work of production and distribution, and the engineer, as heretofore, with the task of devising the means of making the necessaries and comforts of life ever more abundant and more generally accessible.

## TENDERS.

### REDRUTH WATERWORKS.

For the construction of a large storage reservoir, intake works at Lower Penstruthal and Gordon, cast iron mains and laying, &c. Engineer, Mr. H. Bertram Nichols, C.E., Birmingham. Quantities by the engineer.

*Accepted.

The Incorporated Association of Municipal and County Engineers.—The following gentlemen having satisfied the examiners, at the examination held in Birmingham on October 5th and 6th, have been granted the Association's certificate:—James G. D. Armstrong, Henry G. Bradshaw, Amos Burton, jun., William S. Green, Edward W. Hickes, Albert H. Hughes, Edward B. Newton, James Openshaw, William A. Palliser, Joseph Perkins, William Slater, Frederick Thackeray, and Frank Worrall. The next examination will be held in London on April 5th and 6th, 1895.

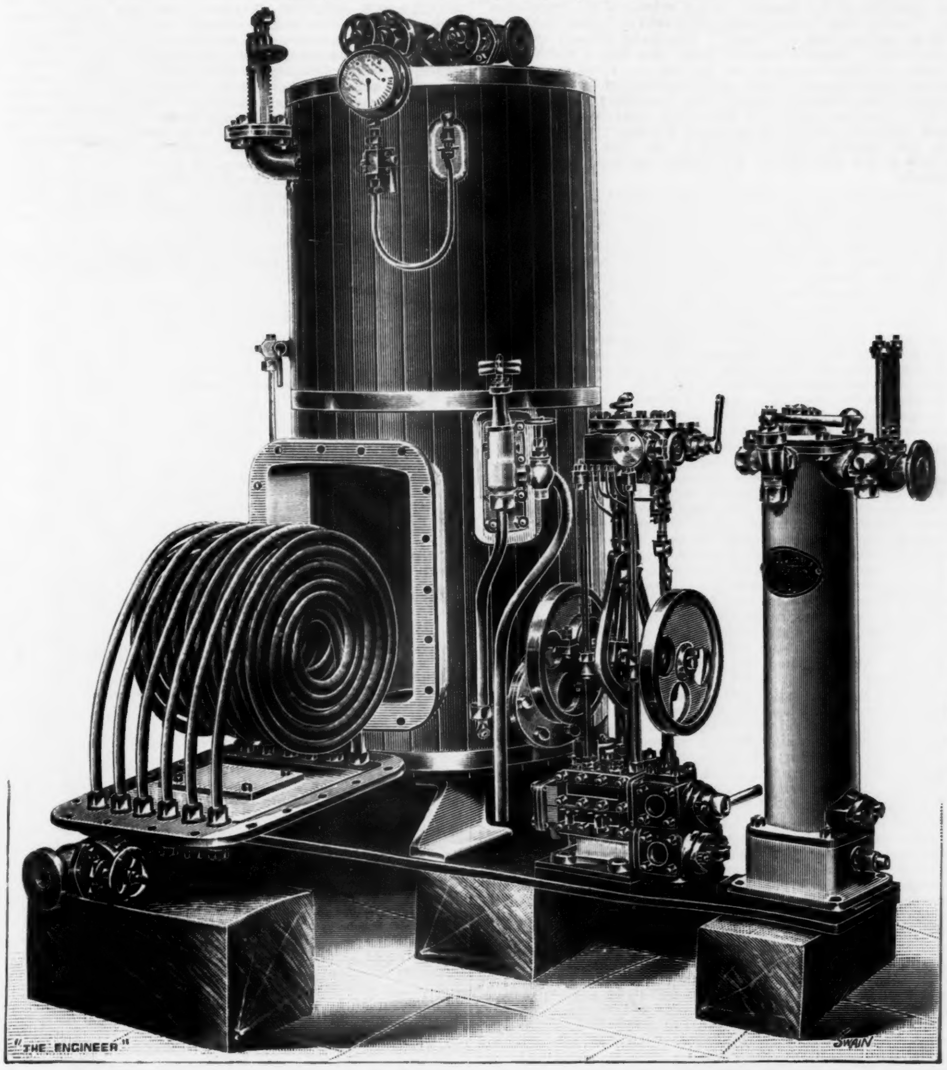
* Read 24th October, 1894.

# THE COMPACTUM EVAPORATOR AND DISTILLER

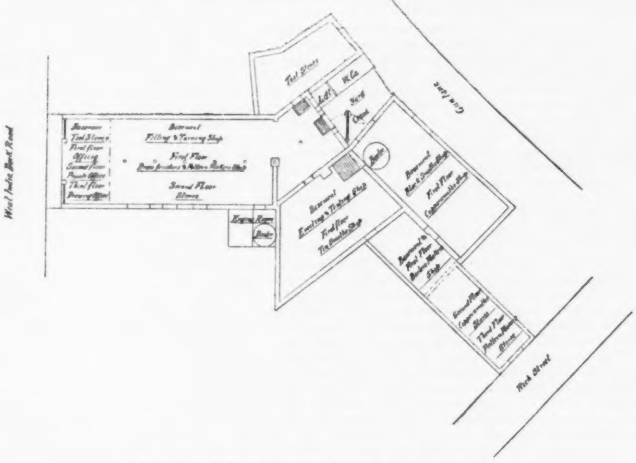
MESSRS. JOHN KIRKALDY, LONDON, ENGINEERS



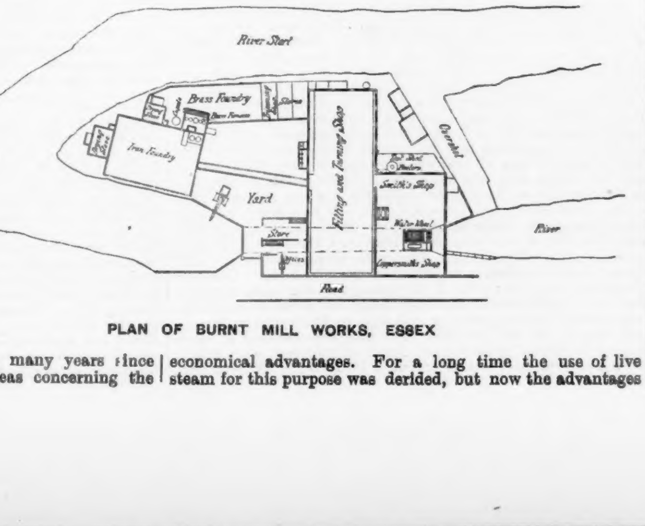
## KIRKALDY'S EVAPORATORS AND THEIR MANUFACTURE.

We have recently had an opportunity of inspecting a complete evaporating and distilling plant, such as is being fitted in vessels of the torpedo destroyer class, and which is entitled to some notice on the score of efficiency, light weight, and general compactness — a combination especially valuable in these small engine-rooms.

Our illustration, Fig. 1, shows the plant as designed and manufactured by Messrs. John Kirkaldy, Limited, West India Dock-road. About this plant the following figures are of interest:—The total weight of the plant, with water at requisite height, is only 1841 lb., disposed as follows:—Evaporator, 1180 lb.; pump, 206 lb.; distiller, 120 lb.; water, 330 lb.; the necessary spare gear would add 134 lb., bringing up the entire total to 1975 lb. The height is 5ft. 11in.; greatest width, 4ft. 4in.; and depth, 2ft. 9in. When it is borne in mind that the "feed-make-up" produced is 10 tons per diem, and that produced for drinking purposes another two tons, the weight of this machine for these outputs seems strikingly low, and shows how much Mr. Kirkaldy has achieved by constant and careful improvements. He has, it need hardly be said, met with the too frequent fate of those who strike out into new paths, and has been followed by a large number who, unable to initiate, are able to derive advantage from initiation by others, and in following, to attract much of the attention that would otherwise be accorded to the leader. Imitation is a form of flattery which may not be unaccompanied by pleasure experienced by the flattered, but Messrs. Kirkaldy complain that this pleasure is not worth what it costs. It is not many years since Mr. Kirkaldy put into practice his ideas concerning the importance of heating feed-water by methods which kept the water free from oil and other impurities, whether the heat for the purpose were obtained by exhaust or by live steam, and he proved that the latter might often be used with advantages which, under some circumstances, became economical advantages. For a long time the use of live steam for this purpose was derided, but now the advantages are generally acknowledged, and Mr. Kirkaldy's methods and apparatus widely employed.



PLAN OF WEST INDIA DOCK ROAD WORKS



PLAN OF BURNT MILL WORKS, ESSEX

The successful working of some feed-heaters and make-up feed evaporators has only been achieved by minute attention and special devices, which long experience and new inventions have made possible, and there are probably no manufacturers who have done so much in initiating and developing these now indispensable adjuncts to the high-pressure marine engine as the one to whose works we now refer. It is not only for the supply of water for potable purposes on board ship that evaporator or distiller plant is used, but for the much larger supply for boilers, which could not now be worked without this means of supply. Previous to the manufacture of the compact apparatus made by Mr. Kirkaldy, the space required for plant for so large a supply would have prohibited its use. The employment of these feed-heaters supplied with live steam, and placed between the feed pump and the boiler, has afforded most important aid to economical marine engine working. Live and exhaust steam feed-heaters and various forms of condensers are made on the Kirkaldy system for electric light stations, and for many places where the possible life of boilers is now, in consequence, much greater than would have been possible with high pressures without such aids.

The importance of the services frequently called for from the firm by the transport department of the Admiralty, in execution of large installations of distilling plant, may be gathered from the leading part it took in such work during the Zulu War and during the Soudan Expedition; the two Cape, Ashantee, and Italian Massowah Expeditions, when Messrs. Kirkaldy sent out distilling plants to produce upwards of 250,000 gallons per day. The plant carried by the Calabria, in fact, at Suakim, was the largest installation of condensing machinery ever put into one ship. Some of our readers may perhaps not remember that the Admiralty chartered the Calabria from the Telegraph Construction and Maintenance Company for trooping purposes during the Soudan Expedition, and gave Messrs. Kirkaldy the order for the distillers with filters, each being capable of producing 6000 gallons of cold water every twenty-four hours, or a total of 64,000 gallons a-day, two of the ship's main boilers supplying the necessary steam; or in other words, acting as evaporators. A donkey boiler drove the circulating pumps, two being in constant use, each throwing 16,000 gallons per hour. This plant was fully described and illustrated in our issue of October 30th, 1885. H.M.S. Wye, during the Ashantee Expedition, and the hired troopships Thames and Sprite, also carried similar plants in 1874.

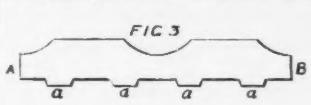
The present business of John Kirkaldy was founded by Mr. John Kirkaldy, grandfather of the present owner, in the year 1809, the firm being converted into a limited company in 1887. The establishment in the West India Dock-road—of which we give a plan, Fig. 2—comprises pattern shops, brass finishers', smiths', and boilermakers' shops, and a well-equipped machine shop which is capable of dealing with much heavier work than purely the firm's specialities. Marine repairs form an important branch of the work with which this plant has been designed to deal. There is a heavy lathe with a 7ft. face-plate, taking 40ft. between centres, by Whitworth, which has in its day turned a shaft weighing 7 tons. This is the largest lathe here, there being many others also by Whitworth, about which there is nothing especially noteworthy. Power for the machine shop is supplied by a 20-horse power engine, made by the firm, of compound tandem type, getting steam from one of John Fraser's vertical boilers. There is another smaller engine which drives the blowing fan for the smiths' fires when the larger engine is not running—during the night, for instance, when the smiths are working late.

All round us we see evidences of a considerable press of work—parts of feed-water filters, distillers, feed pumps, air pumps, circulating pumps, surface condenser combinations, &c., lying about in profusion—more or less disembodied—waiting for the erector. Galvanised shells are being banged and thumped, and if capability of giving a maximum amount of noise for a minimum weight of blow was considered a desirable feature, they should be of excellent material.

The testing department is well equipped with the necessary pumps, tanks, &c., the utmost care apparently being taken to secure accurate results not only in testing the finished article, but in the constant experimenting with new arrangements and devices.

Off the testing department is a boiler shop, where the most noticeable of the heavy tools is a combination of punching and shearing machine, and an engine to drive it, by Craig and Donald. Here the shells for the evaporators are being bent and riveted. In connection with this part of the work, the method of forging in the adjoining smiths' shop the square box which carries the tube plate is interesting, inasmuch as it is, flanges and all, in one piece. The plate which is worked up is first cut as shown in Fig. 3, the excrescences, *a a a a*, being left to supply material in turning the corners of the flange — namely, *a a a* in Fig. 4 — the two ends, A and B, being united at the dotted seam in Fig. 4. In the smithy there are sixteen forges, and a steam hammer by Thwaites and Carbutt. A Waygood lift is kept continually at work communicating with the three stories. One of Llewellyn's patent timekeepers does all the necessary checking of the men's attendance, the number employed being in all about 185, including those at Burnt Mill.

FIG 3



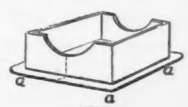


FIG 4

The West India Dock-road premises grew and grew till in 1886 there was no further room for growth, and the firm had to extend elsewhere. This they found at Burnt Mill, Essex, twenty-five miles from London, on the Great Eastern Railway Company's main line, and Fig. 5 is a plan of their premises at that place. Here are large brass and iron foundries, machine, erecting, smiths', and coppersmiths' shops, all fitted with plant and tools of improved types. There is besides great convenience in being alongside the river Stort, so that the establishment enjoys the advantage of both rail and water carriage. Power is derived for driving all the machinery from an undershot water-wheel. The fitting shop has a 40ft. span, traversed by an overhead travelling crane by Smith, of Rodley, near Leeds, to lift eight tons, the same firm having supplied another for the foundry to lift ten tons on a similar span. The majority of the lathes here are by Smith and Coventry, except the largest, which carries a 10ft. face-plate and takes 40ft. between centres, and was made by Smith, Beacock, and Tannett. It is a little amusing to see an old ship's bilge pump doing excellent service in driving the shafting when the river is too low, steam being supplied by a vertical boiler by Clarke, Chapman, and Co.

In conclusion, our thanks are due both to Mr. Kirkaldy and his manager, Mr. Seabury, who kindly gave us much of their valuable time.

## MANCHESTER ASSOCIATION OF ENGINEERS.

The present session of the Manchester Association of Engineers was opened on Saturday by an inspection of the Manchester Corporation Electric Works and the hydraulic power station, after which a social gathering of the members was held at the Grand Hotel, and during the evening there was an interesting display of various exhibits appertaining to electrical engineering. The inspection of the electric and hydraulic stations occupied the afternoon, but as both these important municipal undertakings were pretty fully described during the recent visit of the Institution of Mechanical Engineers, any further detailed notice of their general arrangement and plant is not now necessary. It may, however, be added that the demands upon the electric works have increased so rapidly that further extensions are now absolutely necessary. At present there are 39,268 incandescent lamps of 8-candle power, 256 arc lamps, and ten motors connected to the mains, which are being rapidly extended in every direction. To meet the increasing demand an additional boiler, similar in all respects to those previously put down, and two additional 400 indicated horse-power engines and dynamos, identical with the existing ones, have been ordered, and they are now in course of erection; whilst a third centrifugal pump for the condensing water, to be driven by an electric motor, is also to be put down. In connection with the hydraulic power station, about ten miles of hydraulic mains have so far been put down throughout the business area of the city, and although power has only been available since the 1st February last, agreements have been already signed for the supply of power to 270 machines, comprising passenger elevators, goods hoists, cranes, presses, intensifiers, &c. The power, it may be added, is maintained continuously day and night, including Sundays, and is charged for according to quantity consumed, as measured by meters.

After the inspection of the above works, over which the members, numbering about 150, were shown by Mr. F. M. Evanson, engineer of the hydraulic station, and Mr. C. H. Wordingham, engineer of the electric works, a visit was made to inspect the various interesting electrical appliances on exhibition. Amongst these was a portable electric drill sent by Wm. T. Taylor, of Manchester, which attracted a good deal of attention. This drill, which was in operation during the evening, has been designed to meet the requirements of work too heavy or inconvenient to be brought to a fixed drill, and the gearing has been designed to give great power in a small compass, combined with a very small loss through friction. The total weight of the drill is a little over 200 lb., but to facilitate its being placed in position it is so designed that by loosening two bolts it can be quickly divided into three pieces and readily put together again when placed in position. The pillar which carries the radial arm is screwed, and has nuts upon it by which it is easy to raise or lower the arm, and by means of which the arm can be swung round to any position without risk of dropping. The feed is either automatic or by hand, and the change can be made instantaneously. The electric power required to drill a 1in. hole at the rate of 1in. deep in three minutes is stated to be 9 ampères at 55 volts, and the machine can drill from ¼in. to 1½in. The whole machine is very simply arranged, and although the speed of work is perhaps not to be compared with what is accomplished by a heavy machine, it is satisfactory for a portable tool of such light weight, whilst an advantage of this drill is, that by putting full power on the motor it adjusts itself to the right speed for any size of drill from ¼in. to 1½in., so that time is not lost by the workmen running too slowly. The evening was brought to a close by votes of thanks to the Corporation officials and others who had contributed so much towards the interesting character of the opening proceedings.

## AUSTRALIAN ENGINEERING NOTES.

(*From our own Correspondent.*)

The Melbourne Tramway and Omnibus Company's report shows that a profit had been made for the year of £19,723, which together with the balance brought forward from last year, enabled a dividend of 5 per cent. to be paid, and a balance of £18,057 to be carried forward. The revenue has still declined, but the savings effected have nearly equalled the falling-off in the receipts. The employés have again suffered a reduction of 5 per cent. in their wages.

The profit and loss account for the year ending June 30th is not without interest to tramway engineers here. The expenditure is as follows:—Expenses of tramway trust, £476 2s.; feed, £4777 17s. 4d.; gas, municipal rates, licenses, insurance, &c., £7308 3s. 4d.; law charges and costs, £2013 16s. 5d.; salaries of staff and directors' and auditors' fees, £14,100 15s. 10d.; rating of tramway lines, £1094 1s.; repairs and maintenance of cars, buildings, and lines, £43,700 18s. 4d.; fuel, £13,268 18s. 5d.; wire ropes, £16,521 14s. 5d.; stationery and office expenses, £2313 2s.; wages, £109,871 9s.; depreciation of leaseholds, £1295 19s. 6d.; tramway debenture interest, £76,050; tramway debenture sinking fund, £25 950; tramway renewal reserves, £26,207 13s. 9d.; balance, £42,056 17s. 8d.; total, £387,007 9s. The income was:—Balance forward from last year, £22,333 18s. 5d.; advertisements, £617 10s.; interest, £3306 3s. 1d.; manure, £102 12s. 3d.; rent, £1054 8s. 10d.; transfer fees, £45 16s. 6d.; traffic receipts, £359,546 19s. 11d.; total, £387,007 9s.

A more settled prospect for the revival of trade in New South Wales is looked for since the return of the free-traders in the new Parliament, which, with the increased exports of wool to America, now that the wool is placed on the free list, is a sure indication of immediate prosperity. The phenomenal finds of gold in West Australia still continue throughout the various fields, and are causing increased activity in that colony. The Government is about to float a loan to provide for the construction of railways to three of the new gold fields.

The annual report of the Queensland railways is just published. The result of the working for the year ending 30th June last shows that the depression has affected those railways considerably. The gross revenue shows a decrease of £66,930 on the previous year; one of the principal causes of the decreased revenue is accounted for by the heavy losses in live stock consequent upon the protracted drought.

After an almost complete cessation of railway construction for the last few years in these colonies, a revival may now be looked forward to. In Victoria a committee was appointed by Parliament some time ago to investigate on the advisability of constructing narrow gauge light lines in agricultural districts, and from the evidence tendered, the committee appear to be strongly impressed with the practicability of the 2ft. 6in. gauge, and recommend the laying down of an experimental line. Conferences held between the Premier and the Chief Commissioner for Railways in New South Wales point to an early construction of light lines of standard gauge in the country districts.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*American locomotives for Brazil.*—The Brooks Locomotive Works are building for the Central Railway of Brazil thirty locomotives, of which fifteen are immense freight engines of the "mastodon" or "twelve-wheel" type, having eight driving wheels and a four-wheel leading truck or "bogie." They have Belpaire fire-boxes, eight-wheel American tenders, large cabs and a roof over the tender footplate for use in the wet season. These engines have already been shipped. They have cylinders 21in. by 26in.; driving wheels, 54in. diameter; boiler, 68in. diameter; boiler pressure, 180 lb.; fire-box, 114in. by 39in. The total weight of engine and tender is 251,100 lb., or about 112 tons; with 138,600 lb. on the driving wheels, 30,000 lb. on the "bogie," and 82,500 lb. for the tender. Air brakes are fitted to the driving wheels.

*Brush mattress work for shore protection.*—On the Upper Mississippi River considerable work is being done to protect the shores by means of dams or groins of brush work filled with stone, and by means of brush mattresses. The Government specifications provide that the dams shall consist of brush made into fascines and loaded with rock. The fascines may be laid one at a time or in mats, except in places where the water is over 2ft. deep, when they must be made into mats. Where only one layer of brush is laid, the covering of rock is 1ft. thick at the tips and butts, and 2ft. at the middle of the dams, if required. When more than one layer of brush is used, the bottom layer is covered with rock 6in. thick at the upper side, and 18in. at the lower side, if required. On this rock a second layer of brush is laid, 10ft. or 15ft. farther up stream than the lower layer, and this second layer is fastened and covered as the lower. Additional layers are similarly placed and covered, except that they each are placed and laid 2ft. farther up stream than the one immediately below it, and the top layer is covered with rock, as where a single layer of brush is used. In places the fascines and mats are fastened by stakes driven through them into the ground. When the mats or fascines are laid upon a dry bar, a trench 12in. to 18in. deep is excavated for them. The shore protections consist of a layer of fascines made into mats, sunk at the foot of the slope of the bank, extending out into the river and up the slope as far as may be necessary, with a covering of rock from 9in. to 2ft. thick, evenly and compactly laid. The upper portion of the slope is usually covered with rock alone. The bank to be protected is trimmed to a regular slope of one to two, and all trees, stumps, snags, &c., removed, before the protection is laid. The fascines are made of live brush, well trimmed and closely choked, 20ft. long, and from 12in. to 15in. diameter, and tied with bands of tarred rope or wire not more than 3ft. apart. When made into mats they are closely packed, and secured by at least three pairs of binding poles, joined by ties of tarred rope or wire not more than 2ft. apart. The mattresses or mats are from 12in. to 15in. thick, and not less than 12ft. long. The rock is of a kind that will not disintegrate on exposure to the action of the water and atmosphere; its minimum size for top covering and shore protections being 6in. cubed, or an equivalent thereto, and not larger than 10in. cubed, or its equivalent. A sufficient amount of small rock or gravel is used to fill all interstices and form a compact mass.

*Water power canal.*—Contracts are soon to be placed for the construction of a water power canal about 40,000ft. long, commencing on the upper Niagara river some miles above the falls, and discharging into the lower Niagara river near its Lake Ontario mouth. The canal will have a sudden drop at the end of the bluffs forming the high ground through which the river cuts its way, and on the low ground between the bluffs and the lake shore will be established a manufacturing city for utilising the water power. The canal will be 40ft. wide on the bottom, a water depth of 18ft. in earth, and 25ft. in rock, and side slopes of 1 to 1 in earth, and 1 to 10 in rock. The contracts will be let in eight sections, and the amount of excavation will comprise 4,304,000 cubic yards of rock, and 1,318,000 cubic yards of earth, or 5,622,000 cubic yards in all. Whenever the length of haul of the excavated material exceeds 1000ft., the contractor will be compensated for the overhaul. The contractor on each section is required to excavate and remove an average of not less than 2000 cubic yards per working day. The bottom and sides are to be brought carefully and uniformly to the required lines and grades, no depressions more than 1ft. deep being allowed, and all exceeding that to be filled up by the contractor. As to classification of material, the specifications say that solid rock shall include all rock in ledges, and also detached masses of more than two cubic feet, which in the opinion of the engineer cannot be removed without blasting. Earth comprises all material, of whatever nature, that does not clearly come under the classification of solid rock.

*Pumping engines.*—The Chicago water supply plant is to have five new pumping engines with an aggregate capacity of 88,000,000 gallons per twenty-four hours, partly to replace older engines and partly to afford increased supply. In the Chicago Avenue pumping station will be two vertical compound engines of 15,000,000 gallons daily capacity each; 1,150,000 foot-pounds duty per pound of anthracite coal; 120 lb. boiler pressure; 185ft. per minute maximum piston speed. The Fourteenth-street station will have a vertical triple-expansion engine of 30,000,000 gallons daily capacity; 1,300,000 foot-pounds duty; 120 lb. pressure; and 200ft. per minute piston speed. The Sixty-eighth-street station will have a horizontal four-cylinder engine of 14,000,000 gallons capacity; 1,100,000 foot-pounds duty; 80 lb. pressure, and 130ft. piston speed. A similar engine to this last will be placed in the Lake View station. The maximum stroke of piston for all the engines is 5ft. The boilers are to be of the return tubular type. All the engines are to be capable of running at a piston speed 10 per cent. above the specified maximum without injury. Cast iron is to be of such a quality that test bars 1in. square and 4ft. 6in. between supports will stand a central load of 500 lb., and show a tensile strain of 24,000 lb. per square inch. Cast steel is to have an ultimate strength of at least 57,000 lb.; elastic limit, 30,000 lb.; elongation, 25 per cent. in eight inches; reduction in area at point of fracture, 25 per cent. Wrought iron to have 50,000 lb. tensile strength; 30,000 lb. elastic limit; 20 per cent. elongation in eight inches, and to bend 180 deg. on a curve whose diameter is equal to the thickness of the test piece. Steel forging to have 0·22 to 0·32 per cent. carbon; 0·035 to 0·05 phosphorus, and 0·03 sulphur. Steel plates, 55,000 lb. to 62,000 lb. tensile strength, and not more than 0·03 sulphur or 0·04 phosphorus.

*Steel statistics.*—The following details are taken from the report for 1893 of the American Iron and Steel Association. Production of Bessemer steel ingots, 3,215,686 tons; Bessemer steel rails, 1,129,400 tons; open-hearth steel, 737,890 tons; total steel production, 4,019,995 tons. The production of all kinds of steel rails in this country, including Bessemer and open-hearth steel and iron rails, was 1,136,458 gross tons, a decline of 415,386 tons from the total product of 1892, and the smallest output since 1885. This is partly accounted for by the fact that only 2828 miles of new railways were constructed in 1893, against 4648 miles in 1892. The new railway mileage of 1893 was the smallest since 1878; but in the first half of 1894 only 525 miles have been built. At the close of 1893 there were forty-three completed standard Bessemer steel works, with ninety-five converters, and one new plant with two converters was in course of erection in Ohio. No Clapp-Griffiths steel plants have been built since 1889, and the total number of present works of this type is four, with seven converters. Only three were in operation in 1893. Of the four Roberts-Bessemer plants in the country, with six converters, only one was in operation last year. Bessemer steel, including the products of the above plants, was made in thirteen States in 1893, though Pennsylvania, Illinois, and Ohio lead in this industry. The production returns of open-hearth steel in the United States include steel made in the open-hearth by the basic process, and the output of 1893 was 737,890 gross tons, against 513,232 tons in 1890, the increase of output being continuous for the intervening years. In the year considered 63,613 tons of crucible steel were made, as compared with 84,709 tons in 1892. The report gives the figures for all kinds of iron and steel rails rolled in the United States for each year since 1848. It commences with 21,712 tons in 1849, rises to 183,070 tons in 1860, 553,571 tons in 1870, 1,305,212 tons in 1880, and 1,885,307 tons in 1890. The maximum output recorded is 2,139,640 tons in 1887. The exports of domestic iron and steel manufactures from the United States to all foreign manufacturers were valued at 30,159,150 dols. in 1893, against 27,900,862 dols. in 1892. In these exports cut nails and spikes form the chief item, the valuation being 10,512,576 dols. in 1893 and 10,348,675 in 1892. Agricultural implements come next, with 5,191,223 dols., and then come sewing machines with 2,456,487 dols., both of the latter for 1893. The wire nail industry has made wonderful strides in the United States since the output of 600,000 kegs, of 100 lb. each, in 1886. In 1889 the production had risen to 2,435,000 kegs, and in 1893 it was 5,041,945 kegs, the highest on record. The total of cut nails, which was 6,493,591 kegs in 1888, had fallen to 3,048,933 kegs in 1893.

*Railway statistics.*—I give this week some figures from the report of the New York Central Railroad for the year ending June 30th 1894:—

| | |
|---|---|
| Mileage | 5214 |
| Passenger earnings, dollars | 14,151,279 |
| Freight earnings, dollars | 24 104,509 |
| Gross earnings, dollars | 43,678.200 |
| Operating expenses, dollars | 29,508,406 |
| Net earnings, dollars | 14 169,794 |
| Percentage of operating expenses to gross earnings | 67·57 per cent. |
| Passenger train mileage | 14,374,625 |
| Freight train mileage | 14,118,939 |
| Total train mileage | 40,280 825 |
| Total passengers | 23,602,243 |
| Passengers carried one mile | 742,542,163 |
| Total freight tonnage | 18,728 592 |
| Tons hauled one mile | 3,275,998,571 |
| Earnings per passenger per mile, cents | 1·90 |
| Expenses per passenger per mile, cents | 1·46 |
| Profit per passenger per mile, cents | 0·44 |
| Average passengers per train mile | 52 |
| Average miles each passenger | 31 |
| Freight earnings per ton per mile, cents | 0·74 |
| Freight expenses per ton per mile cents | 0·57 |
| Freight profit per ton per mile, cents | 0·17 |
| Freight earnings per train mile, cents | 1·83 |
| Freight expenses per train mile, cents | 1·42 |
| Freight profit per train mile, cents | 0·41 |
| Average number of tons per train mile | 249 |
| Average miles each ton was hauled | 175 |
| Number of locomotives | 1211 |
| Number of cars in passenger service | 1488 |
| Number of cars in freight service | 39,302 |
| Capital stock, dollars | 94 273,400 |
| Cost of road and equipment, dollars | 157,468,008 |
| Number of employés | 27,088 |
| Amount of pay rolls, dollars | 16,439,064 |

*Government supervision of railway accounts.*—In view of the extensive fraudulent transactions in railway accounting and the enormous "steals" that have been perpetrated, resulting in great loss to the smaller investors, an agitation is being made in favour of having railway companies' accounts supervised and audited by Government officials in the same way that banking companies' accounts are inspected and supervised. This work would be a part of the duties of the Inter-State Commerce Commissioner. The proposition which seems to find special favour with those who advocate absolute Government control is the appointment of examiners similar to national bank examiners, with authority to visit railway offices at any time and overhaul every item of their accounts and securities. That the United States have full authority to impose such conditions as they choose upon railways engaged in Inter-State commerce is argued from the fact that the right to engage in such commerce is a specific grant by Congress. The friends of such legislation claim that it would do more to prevent violation of the Inter-State Commerce Act than all other provisions of the Act combined. It would put an end to the necessity of hunting evidence through aggrieved shippers, discharged employés, and detectives. The Inter-State Commerce Commission would be in absolute possession at any time it wished of the exact state of the accounts of every great railway corporation. Secret rebates, false bookkeeping, and the hypothecation of securities for private use, would be instantly disclosed by the discrepancy between the books and the cash. The method of accounting would be uniform for all roads, and the returns for one could be intelligently compared with those for another by the investing public. The Inter-State Commerce Commission already requires uniform annual reports from the railways, and issues a pamphlet giving instructions how these accounts shall be prepared, but they have no check upon false entries, and no power to prevent the keeping of private records of rebates, and the publication of reports essentially different from the ones submitted to them for influence upon the stock market. It is reported that a movement to regulate railway accounting is under way in New York, independent of the action of Congress or the Inter-State Commerce Commission. A body of eminent financiers with competent experts would be formed, under this plan, into a board of railway auditors, and it is believed that railways honestly conducted would gladly submit their accounts, and throw open their books to the examination of such a board. The certificate of proper bookkeeping and of an actual surplus, instead of a fictitious one, would be of great value to the roads submitting their accounts to such examination, and the refusal of a road to invite this form of guarantee would in itself be a cause of suspicion. Whether this method would be successful is doubted by some of the advocates of Federal regulation, but it is thought that it may be tried, if action by Congress cannot be obtained. Such action at the coming session is considered doubtful.

Maxim's Flying Machine.—An exhibition of the flying machine to the general public, the first of its kind, will be given by Mr. Maxim, in aid of the funds of the Bexley College Hospital at Bexley, on Saturday afternoon, November 3rd. The machine will be run along the track at a high velocity; but to suit all states of weather, only the main aëroplane will be in position. The large workshop will be open to visitors, and scientific instruments used by Mr. Maxim in his experiments will be on view. During the afternoon there will also be a practical display by Mr. Maxim of his automatic machine guns. The only entrance to the Park on this occasion will be at the Lodge, on Dartford Heath. Gates open at 2 p.m; proceedings commence at 2.45.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet engineer—Richard G. Callaway, to Philomel. Staff engineers—W. F. Abbott, to the St. George; George Aborn, to the Cambrian; W. A. Howlett, to the Grafton; John W. Henwood, to the Narcissus; and Charles Underhill, to the Emerald. Chief engineer—Charles A. Harding, to the Pembroke, reappointed on promotion. Engineers—Frank D. Thomsett, to the Charger; Walter K. Williams, to the Ardent; A. C. Darley, to the Grafton; Frank Main and George Attwool, to the St. George; Frederick H. Dart, to the Defiance; Henry Abbott, to the Cambrian; Arthur C. Darley, to the Grafton; George L. R. Perkins, to the Pembroke, supernumerary; Frederick G. Dawson, to the Philomel; Frederick C. Davis, to the Warspite; and Harry Basson, to the Thrush. Assistant-engineer—Thomas J. Dawson, to the Thunderer. Probationary assistant-engineers—Arthur Brown and Wellesley J. Steil, to the St. George; Herbert G. Ash and Henry T. Canning, to the Cambrian; and Thomas Pearce, temporary service, to the Philomel.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

BUSINESS in the district iron trade has a healthy tone, and the orders which have been distributed at and since the quaterly meetings have stimulated operations to a considerable extent. Producers of the best finished iron report themselves as having transacted a larger business of late than has been the case for some time. Among the new orders recently to hand is one mentioned for chain cables required by the Admiralty, which is estimated as worth over £20,000. Marked bars are on sale at £7 10s., with the usual 12s. 6d. extra for the L.W.R.O. brand; merchant bars £6 to £6 10s., and third class quality bars £5 10s. to £5 12s. 6d., though in some instances less is accepted. It is stated that the sum paid for the trade marks used in connection with manufactured iron produced by the late New British Iron Co. was £2000. Common iron hoops are this week quoted £6 5s. to £6 10s., and gas tube strip £5 10s. easy. A tolerably good request is forthcoming for galvanised sheets for Australia, South America, and the Cape, but local makers complain much of underselling by some firms. It is hoped, however, that this competition will be avoided by the operation of the National Galvanised Sheet Iron Association, which it is proposed to form. The association is, if established, to include all the makers in Staffordshire, and the Midlands, the West of England, Lancashire, Cleveland, and Scotland, and penalties are to be attached to any departure from the Association price. The general quotation of corrugated sheets, doubles, this week is £9 15s. per ton f.o.b., Liverpool in bundles. Plain doubles are £6 12s. 6d. to £6 15s.; trebles, £7 5s. to £7 7s. 6d. Pig iron sellers express themselves satisfied with the business lately done. Imported brands from Derbyshire, Lincolnshire, Northamptonshire and elsewhere, are in prominent request. Staffordshire part mines are 41s. 6d. to 42s., and cinder 38s. to 40s.

Prosperity, it is gratifying to note, is attending the operations of the St. George's Engineering Co. The directors, in submitting a statement of accounts for a period of eleven months, state that the business continues satisfactory. The amount available for distribution is £3285 3s. 9d. This they propose to appropriate as follows:—In payment of a dividend of 7½ per cent. per annum, £1749 19s. 9d.; in reduction of goodwill, &c., £1000; to carry forward, £535 4s.

Matters in the wrought nail trade of Warwickshire, Staffordshire, and Worcestershire, have of late been somewhat strained, but an arrangement was come to lately to pay on all classes of nails the 1892 list of prices less 10 per cent., wherefore amicable relations have now been re-established.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The position generally throughout the engineering and iron trades of this district continues without any really material change. It is still only in exceptional cases where engineering firms report any increasing activity, whilst in other cases the outlook is regarded as, if anything, even more unsatisfactory than it has been; and taking the condition of trade all through, it is only very indifferent, with any prospect of improvement apparently quite as remote as ever. In the iron and steel markets business still drags on in a hand-to-mouth sort of fashion, with a gradual weakening tendency in prices, which seem to be surely but slowly getting back to something like the old low figures. The position in the coal trade also is anything but satisfactory, as apart from housefire qualities, which are necessarily meeting with an increasing demand as the winter comes on, general requirements continue considerably below the supplies coming upon the market.

The Manchester Iron Exchange on Tuesday was fairly well attended, but complaints were general as to the absence of business of any weight coming forward. Here and there moderate inquiries for pig iron were reported, but in most cases the offers of buyers were below what makers seemed inclined to entertain, and where business is done prices as a rule have to give way to some extent upon recent quotations. For Lancashire pig iron makers still quote on the basis of about 39s. 6d. to 40s. for forge and 42s. for foundry, less 2½, at the works, but they are practically out of the market so far as open competition is concerned, the limited business doing at these figures being confined chiefly to small sales to regular customers. For district brands prices are rather easier, although some of the makers are altogether indifferent about booking further orders. In Lincolnshire forge sales have been made at about 38s. 6d. to 38s. 9d. net cash delivered Manchester, but for foundry qualities quotations remain firm at about 40s. 6d. net cash delivered. In Derbyshire foundry prices are rather irregular, ranging, according to brand, from 44s. 6d. to 45s. up to 46s. net cash delivered Manchester. With regard to outside brands offering here, Middlesbrough remains firm at about 44s. 4d., net cash, for good foundry qualities delivered equal to Manchester, with makers still asking 6d. above this figure for special-named brands. Scotch iron is necessarily easing down with the resumption of output in Scotland, and representatives of makers who are again offering in this market are finding that during the stoppage of production—through the strike—merchants here have been booking what business there was to be got, for delivery when the furnaces re-started, at considerably under the prices that were then being quoted in the market. For delivery at the Lancashire ports Eglinton is now being quoted at about 48s. net prompt cash, but in some cases might be bought a little under this figure.

In the finished iron trade there is still no move whatever towards any improvement, business coming forward only in very limited quantities, and forges not working on an average more than four to five days per week. Makers hold on to late quotations, but these are becoming difficult to maintain upon new business. Delivered equal to Manchester or Liverpool, Lancashire and Staffordshire bars remain at £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.: and Lancashire hoops, £5 17s. 6d. for random, to £6 2s. 6d. for special cut lengths.

The steel trade all through continues extremely quiet, with hematites practically back at their old figure, ordinary foundry qualities not averaging more than 52s. 6d., less 2½, with ordinary billets remaining at about £4 net cash delivered Manchester. With regard to manufactured steel ordinary bars may be quoted at £6 to £6 2s. 6d., and boiler-plates about £6 5s. to £6 7s. 6d., although £6 2s. 6d. would seem to represent more nearly the figure which would have to be taken where buyers have business to put through.

In the métal market list rates for manufactured goods remain unchanged, with buyers still holding back from placing orders of any weight, in the expectation of some early giving way upon present rates.

Some time back I noticed the exceptionally successful results which have been obtained with a special system of pumping, introduced by Mr. Thomas Matthews, of Gorton, near Manchester, and this week I had an opportunity of inspecting one of his patent pumps that had been put down at the brewery of Messrs. Gartsides, Ashton-under-Lyne. In this case there had been for some years a bore-hole about 300ft. deep, and in it a pump driven by strong wheels, cranks, and levers, the full capacity of which, under any circumstances, was about 3000 gallons per hour. This supply having been found altogether inadequate for the requirements of the brewery, Mr. Matthews undertook to double the quantity without altering the bore in any way, and, after taking out the old pump, applied his patent system, putting down a very compact engine, working at thirty-six strokes per minute, and occupying scarcely one-fourth the space of the old engine, whilst with the new engine 7000 gallons per hour have been obtained, and lifted to a height of over 200ft. from the bucket. The manager of the brewery informed me that with the new engine and pumps they only required to pump six hours per day, instead of twenty-four hours with the old pumps, and that, with one-quarter of the time thus spent in pumping, they were obtaining a much more adequate supply of water. One of the special features of Mr. Matthews' system is the position in which the pump is put down in the bore-hole, whilst the engine, which is of the vertical type, is exceptionally compact in its arrangement, all the parts easily accessible, whilst, whatever the load, the pumps work without jar or noise.

I was present on Wednesday at a series of important tests carried out at an experimental station which has been put down at the Moss Colliery, near Wigan, for the purpose of testing explosives used in coal mining operations, with regard to their safety under the conditions of a blown-out shot coming in contact with coal dust or an explosive mixture of gas and air in a coal mine, and also as to their relative strength as explosives tested by the distance to which a projectile could be fired from a mortar. The experiments were witnessed by a number of Government mine inspectors, mining engineers, and by official representatives of the Miners' Federation of Great Britain. The various explosives which were put under test were dynamite, roburite, westphalite, bellite, tonite, ammonite, Ardeer powder, and carbonite, and the tests were carried out under the supervision of a committee consisting of Messrs. Joseph Dickinson, late Chief Inspector of Mines; D. H. F. Matthews, Inspector of Mines; J. Ishewood, J.P., miners' agent; and J. S. Burrows, of Messrs. Fletcher, Burrows, and Co., Manchester. After the experiments of firing cartridges of the various explosives into coal dust, the committee reported that the firing of the dynamite, roburite, bellite, tonite, and ammonite cartridges had resulted in complete ignition of the coal dust, large flame, and explosion; westphalite resulted in no ignition, no flame, and no explosion; and Ardeer powder and carbonite in no flame and no explosion. These were followed by experiments, with the object of testing the effect of the most successful explosives when fired in the form of a blown-out shot coming in contact with an explosive mixture of air and gas, and the following results were recorded by the committee:—Carbonite, Ardeer powder, and westphalite, no flame and no explosion; roburite, explosion and flame, apparently of gas only. The results of the tests as to the relative strengths of the various explosives were pretty nearly equal as regards dynamite, roburite, westphalite, ammonite, and bellite; tonite showing considerably less explosive power than the above, whilst Ardeer powder and carbonite, which in the first experiments caused no flame or explosion when fired into the coal dust, had only a very low explosive force, scarcely more than one-third that of dynamite, westphalite, and roburite, and to this low explosive power was due their immunity from flame or explosion in contact with coal dust, which no doubt would have been secured by the other explosives that "fired" if they had been brought down similarly low in power. The general opinion expressed after the conclusion of the experiments was that westphalite—which has already been largely adopted on the Continent, and in the mines of Saxony, which are very dangerous to work, is the only explosive the Government allow to be used—had under the conditions of the tests proved to be decidedly the safest explosive for mining purposes; but in view of the great importance attaching to the safety of explosives used for mining purposes, it was urged not only by the miners' representatives but also by one or two of the leading mining engineers present, that in future, experimental tests of explosives which are claimed to be flameless should be carried out by independent or officially-appointed committees of inspection, so that the relative "safety" properties of the now numerous explosives that are being put forward may be tested in a manner which may give to them some sort of official guarantee.

The better qualities of round coal are meeting with a steadily increasing demand, and pits are gradually getting on to five days per week, but other descriptions of fuel for iron-making, steam and general manufacturing purposes, continue bad to sell, and with plentiful supplies in the market prices show rather a weakening tendency than otherwise. For housefire qualities prices are steady at about 11s. to 11s. 6d. for best Wigan Arley, 10s. to 10s. 6d. for Pemberton four-foot, and seconds Arley 8s. to 8s. 6d. for common housefire coal at the pit mouth. Common round coals for steam and forge purposes, however, are only in exceptional cases fetching more than about 7s. per ton, whilst engine fuel is very irregular in price, surplus supplies coming in from outside districts at excessively low figures. Common Lancashire slack does not average more than 3s. 6d. to 4s., with best qualities averaging about 5s. to 5s. 6d.; but Derbyshire slack can be bought at the pit mouth at as low as 1s. 6d. to 1s. 9d. per ton.

Here and there moderate business is still reported for shipment; but generally this branch of trade is very quiet, and some extremely low prices have been quoted, common coal being obtainable from about 8s. up to 8s. 6d. and 8s. 9d. per ton, delivered at the Garston Docks or the High Level, Liverpool.

*Barrow.*—There is still a very quiet business in hematite pig iron. Orders are not increasing either on home or foreign account, and the inquiry for forward deliveries is very quiet indeed. The value of hematite is fairly steady at 43s. 6d. net cash, warrant sellers, and 43s. 5d. buyers, while makers ask 44s. to 45s. for parcels of mixed Bessemer numbers, net f.o.b. Only 33 furnaces are in blast, compared with 34 in the corresponding week of last year. Stocks are steady. There has been a slight decrease during the past week, amounting only to 10 tons. There are now in the hematite stores in the district 158,500 tons, being an increase of 63,877 tons since the beginning of the year.

Iron ore is very quiet in tone, and sales are limited. Prices remain steady, at 8s. 6d. for ordinary, and 13s. 6d. for best qualities, net f.o.b.

The steel trade does not show much more life, although prospects are fairly good so far as tin bars, ship plates, and steel castings are concerned. A quiet business is doing in rails, and the mills have this week been busy in the manufacture of steel props and girders for mining operations—a new branch of industry, and of some promise. There is not much doing in blooms, slabs, wire rods, or billets.

In the shipbuilding and engineering trades new business is quiet, and very few inquiries are in the market. Local yards, however, are well off for orders, although they are chiefly on Admiralty account. Repair work is not at present brisk.

The wood pulp and paper works at Barrow have lately been extended and are now in full operation.

Mr. D. Caird, at his new engineering and ironfoundry works at Barrow, has commenced business in the manufacture of steel ingots, &c., and is cultivating a general trade.

The coal and coke trades are very quiet and supplies are limited, but the consumption is very small all round. Prices are a shade easier.

Traffics on local railways remain very low, although a shade better than last year, but prospects of improvement are not good.

Shipping returns show an improvement. The exports of pig iron from West Coast ports during the past week have amounted to 9435 tons, compared with 5580 tons in the corresponding week of last year, an increase of 3855 tons. The exports of steel represent 10,153 tons, compared with 2607 tons in the corresponding week of last year, being an increase of 7546 tons. The aggregate shipments of pig iron this year so far have been 293,295 tons, and of steel 326,230 tons, compared with 222,463 tons of pig iron and 2607 tons of steel in the corresponding period of last year, an increase of 70,833 tons of pig iron and 65,432 tons of steel. Freights are still low.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE weather is so variable, cold and warmth alternating every day, that the reports from various colliery districts get perplexing. In one part it is stated that the cold has caused agents to hold out for higher prices, and in another that there is no actual change in the amount of business doing, while a general languor prevails. The truth is that a fair average trade is doing, and with a continuance of the fog of the last few days, with frost at nights, house coal is certain to be busy. At the same time prices are not so strong in this class of fuel as was expected. The advance of 1s. a ton imposed in several colliery districts was not generally obtained, and where it was enforced it lasted a very short time. The quotations remain pretty much as they were in September. In collieries favourably situated the advance cannot now be put down at more than 6d. a ton. Manufacturing fuel is not likely to be increased, manufacturers complaining that prices have been too high all the summer. The export trade will soon be at an end, and what with this, the reduction of miners' wages, and the absence of any indication of increased demand, colliery proprietors will no doubt be content if present quotations can be maintained. About four and a-half to five days a week are being worked at the pits, but the accumulation of stocks is a sure indication that the demand is still considerably short of the output. The dispute between the colliery enginemen — a far graver matter than has been generally admitted—has been postponed for the present. The men have shown an agreeably peaceful disposition by deferring their notices in order that the matter may have fuller consideration. The conference has been fixed for Tuesday next, and as the difficulty has been arranged between the West Yorkshire owners and their men it is not likely that an amicable settlement will be prevented in South Yorkshire. The leaders of the Men's Federation state that they have no easy task in persuading their members to agree to the delay, the hotter spirits being clamorous for a closure of the collieries wherever their demands were not immediately granted. A considerable tonnage of coal is being sent to London, but sales are slow and agents report the impossibility of obtaining advanced prices. Silkstones are quoted at 9s. 6d. to 11s. 3d. per ton, Barnsley hards from 8s. 6d. to 10s. per ton, other sorts from 8s. per ton. Goole as well as Hull is taking fair quantities of steam coal. The trade on the whole holds up well for the season of the year. The strike in Scotland has favoured Yorkshire collieries to some extent, and the advantage has been maintained during the present month. Barnsley hards—steam—make from 7s. 9d. to 8s. 6d. per ton, second qualities from 7s. to 7s. 6d. per ton. Gas coal is at 7s. to 8s. per ton, with large deliveries on contract account. For manufacturing fuel prices remain at 4s. 6d. to 5s. 6d. per ton, good pit slack being obtainable from 3s. 6d. per ton. A better business is being done in coke, quotations remaining at previous figures.

Steel and iron quotations have not materially changed since last week. The large establishments are anything but fully occupied, and were it not for the important orders on hand for armour-plates there would be no employment for many of their regular hands. East Coast hematites are at 50s. 6d. to 51s. 6d.; West Coast brands, 52s. to 52s. 6d.; forge iron, 38s. to 38s 6d.; Lincolnshire forge iron, 38s. 6d.; Bessemer billets, £5 10s.; bar iron, £5 10s. to £5 12s. 6d.; wire rods, £5 5s.; Roep rods and high carbon rods, £8 8s. In the Rotherham district some considerable orders have been received on Government account, but generally the ironworks are not running full time.

A little more is doing in the engineering establishments, although there is not so much reported as in the closing months of 1892. The demand from the Continent for crucible steel is maintained, the more valuable brands being most in request. Orders for railway material are provokingly scarce, but it would be unreasonable to expect railway directors to expend freely on new stock and plant until the traffic returns exhibit some hope of improvement. Very light business is doing in marine material, owing to the paralysis in the shipbuilding yards. A good line for steel ship-plates has come to one firm, but there is very little to report otherwise.

A steady improvement is reported in the cutlery trade. An increased demand for springs, scales, and blades, orders now being given by grosses instead of by dozens, in good evidence of improvement in that direction. Workmen, as a rule, are finding better employment, and in the absence of wages disputes the winter outlook is more hopeful than was the case last year. In the silver and electro-plate industry the workmen are busily employed, and for the most part have to put in overtime. Some very fine works for presentation purposes have recently been placed in our Sheffield establishments, and the tendency to prefer the sterling silver to plated goods, owing to the low price of the precious metal, is maintained. Saw manufacturers have experienced a light spurt in the country markets. India and the Cape have been fair customers, but very poor business has been done with Australia and South America. Affairs are looking up in Australia, but the Americans are cutting in that colony both in hand and circular saws, and thus attenuating the orders sent to Sheffield.

At the London ivory sales, which commenced on Tuesday, 107¾ tons were offered. Eighty tons are of new importation, having arrived since the termination of the last sales held in July, the remainder being old stocks. Considerably more than half of the East India, &c., kinds consists of large tucks, a fair proportion being of good to very fine quality soft grain, a small quantity of fine hard, and about one-third inferior or defective. Of the Egyptian, a large percentage is particularly free from serious defects, and much is exceptionally large in size, nearly two-thirds of the thirty tons being of the old-fashioned Alexandrian type. Fine qualities are chiefly absent from the West Coast African assortment. All the stock has been carefully inspected by a large number of buyers. On the opening day values varied considerably, and Liverpool advance was not sustained.

The Master Cutler, Mr. C. H. Bingham, gave his accustomed "banquet of the North" on Thursday night, with the Premier, the Earl of Rosebery, as his chief guest. The following day the Master Cutler's guests inspected the works of Messrs. Walker and Hall, silversmiths, electro-platers, and cutlers, Electro Works, Howard-street, Sheffield—of which the Master Cutler is a partner—Messrs. John Brown and Co., Atlas Steel and Iron Works, Sheffield, and Messrs. J. H. Andrew and Co., Toledo Steel and Iron Works, Sheffield. At the electro works, all the various delicate and beautiful processes associated with the production of silver plate, Britannia metal, and similar goods, were seen to great advantage in that large establishment, where upwards of 1000 men are employed. At the Toledo Steel Works, the production of steel for all the varied purposes used in the markets of the world was exhibited. Interest mainly centred in the visit to the Atlas Works. There the visitors saw the rolling of an armour plate for H.M.S. Magnificent, the finished dimensions of which were 15ft. by 6ft. 8in. by 14in., and the weight 25 tons. The process of chilling an armour-plate for the same ship was also shown, as well as the planing and slotting of armour-plates for H.M.S. Magnificent, Majestic, Powerful, and Terrible. In the armour press plates were forged for the Magnificent, one plate when forged weighing 27 tons. In the north machine shop the visitors inspected the turning and boring shaft for the Russian vessel Russia, and boring ammunition hoists for H.M.S. Powerful and Terrible. They were shown the boiler shop containing ten marine boilers, each 10ft. 6in. diameter by 10ft. 6in. long, fitted up with the "Ellis and Eaves" induced draught, capable of producing 8000 indicated horse-power without any smoke. The Master Cutler's guests also inspected the Bessemer process, the hammering, finishing and rolling of steel tires for railway engines and carriages, the Serve tube department, the bending and welding of Purves patent ribbed flues for boilers, &c.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

BUSINESS altogether lacks animation at present, and the improvement which has lately been experienced is disappearing, with little hope that there will be a return on this side the advent of spring, as after this month the quietest period of the year comes on. The chances are not in favour of prices going up again at any early date, and consumers therefore take their time about buying, for by purchasing as they require the material they get the advantage of any reductions that may be made. The outlook is not encouraging for those engaged in any branch of the iron and allied industries. With the close of this month the northern navigation season virtually ends, and very little iron will afterwards be sent to a good many of the ports on the Continent. Thus the consumption of pig iron will be reduced, and as in this month—which should be one of the briskest shipping periods of the year—stocks are increasing, it does not seem likely that the consumption for the rest of the year will be such as to prevent an ever-larger increase in stocks. Production has exceeded consumption in this district ever since last June, just during the very time when the latter should be the larger; and what is more significant still, just over the time when one leading district in the country practically ceased to produce. It would seem as if, to keep the stocks down, the only course open to ironmasters would be to reduce the output. Some of the quietness may be ascribed to political uncertainties abroad, in the face of which consumers do not feel inclined to buy ahead, and speculators are holding back, being rather sellers than buyers.

The market is not now held back by labour disputes, as it has been so much this year. The Scotch miners' strike is ended, and a better demand from that quarter for pig iron may be looked for, as there is abundance of fuel, and the mills and forges have recommenced operations. Locally the only strike of any importance in progress is that of the patternmakers, which has lasted since last April, and the men seem as determined as ever not to give in, a vote taken the other day showing a majority of five to one against any surrender, though it must be evident that they can have no hope of coming out of the struggle victorious. They will not follow the example of the moulders, who, after being five months on strike, agreed to have their difference with the employers settled by arbitration. The patternmakers have less chance of succeeding than the moulders had, for they are a smaller body, and their strike does not inconvenience the masters so greatly. Those who are managing the patternmakers' strike cannot be commended for their discrimination, for their own society's organ shows that trade is depressed and in many places bad. How, therefore, the men on strike in this district expect to succeed in getting an advance in wages cannot well be seen. The formation of a Conciliation Board has just been completed for the moulders of the North-East Coast. The board will consist of eleven employers and an equal number of moulders' representatives. The object of the board is to regulate general advances or reductions in the wages of moulders, but any other general question may, by common consent, be brought before the board. Sir Andrew Noble is elected chairman of the board, and Mr. T. R. Johnson, of Sunderland, vice-chairman, while Mr. James Robinson will be the employers' secretary, and Mr. Henderson will act on behalf of the men. It is arranged that a meeting shall be held next Monday to consider the request of the men for an advance of wages, and the counter-claim of the employers for a reduction. The Durham colliers have decided to claim a 15 per cent. advance of wages. They seem to pay little heed to the advice of their own Executive Council, which most strongly urged them, in face of the negotiations which are going on towards the establishment of a Conciliation Board, to vote for the postponement of any claim of the kind. The employers are not likely to grant any advance, much less an advance of the extent the men have claimed, especially when in the neighbouring county of Northumberland it has been arranged that wages are not to be altered this quarter, the realised prices not justifying any advance. The circumstances in Durham are very similar. Trade has certainly been brisk in the coal industry of the North of England during the continuance of the Scotch strike, and collieries have been kept fully employed, but the advances in price have been insignificant.

The quotation among makers generally for prompt f.o.b. deliveries of No. 3 Cleveland pig iron is 35s. 9d., but some firms can command 36s.—and even more—because they have so very little that is available for sale. Some of the middlemen have this week been selling No. 3 at 35s. 7½d.; but they could only offer small lots. Merchants are not very ready to sell at present prices, as much of the iron they have was bought when prices were higher than at present. When prices were rising there was a great rush to secure supplies, in the belief that there would be a still more substantial rise. Thus the competition of merchants is not now very keen. Cleveland warrants have not varied much in price this week, 35s. 7½d. cash being the highest, and the close on Wednesday evening was at that. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 88,620 tons, or 1125 tons decrease this month. The supply of No. 4 Cleveland foundry pig is very small, and 35s. 1½d. can be secured for it; but for grey forge, of which there is a plethora in the market, scarcely can 34s. be obtained. Mixed numbers of East Coast hematite pig have this week been generally sold at 42s. 9d., though 43s. is mostly quoted. The demand is slack and stocks accumulate, so that it is scarcely likely that any more furnaces will be put upon this class of iron, particularly when the shipping season is now almost at an end, and the local steel trade is so dull. It would be better to blow out than to blow in hematite furnaces. The shipments of pig iron from the Tees this month up to Wednesday night amounted to 62,260 tons against 62,480 tons last month, and 84,599 tons in October last year to 24th.

Finished iron and steel manufacturers as a rule give despondent reports about their business, and not many works are in full operation. Common iron bars are quoted at £4 17s. 6d.; best bars, £5 7s. 6d.; best best bars. £6 7s. 6d.; iron and steel ship plates, £4 17s. 6d.; iron angles, £4 12s. 6d.; and steel angles, £4 15s., all less 2½ per cent. and f.o.t. The rail makers find business very dull, and for heavy steel rails they ask £3 12s. 6d. net at works.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE is now some hope of an early improvement in the iron and coal trades, owing to the termination of the colliers' strike. Since last week the colliers in the East of Scotland—in the Lothians, Sterling, and Linlithgow and Fife—have abandoned the struggle as hopeless, and made a rush for admission to their old places in the collieries, so that the strike is now finally terminated all over the mining districts. It has been a most unfortunate one, not merely for those immediately concerned—the coalmasters and miners—but for the trade of the country generally. The stagnation of trade has been severe as well as general; but it has been succeeded by a feeling of hopefulness, which it is hoped is the prelude to a substantial improvement in business.

The Glasgow pig iron market has been quiet. There has been no occasion for any fresh speculative movement, and business has been on a moderate scale. For Scotch warrants the demand is slow, and prices are ½d. to 1d. per ton lower. A rather better inquiry has sprung up for Cleveland pig iron, the consumption of which in Scotland has, indeed, been comparatively good during the whole period of the strike. On some days there has been a slight tendency towards harder prices for Cleveland pig, but hematites have been comparatively neglected. For the latter, however, it is believed that the demand must now begin to improve, as much more of this class of iron will be required by the steel makers.

A large number of furnaces have been lighted in the course of the week, and there are now thirty-two in operation, compared with fourteen last week and forty-eight at this time last year. One or two brands of pigs that were out of the market can now again be had in moderate quantity. The stocks of makers' iron are low, but the prices have nevertheless been receding. G.M.B. f.o.b. at Glasgow, No. 1, is quoted 44s. per ton; No. 3, 42s. 6d.; Monkland, No. 1, 45s. 6d.; No. 3, 42s. 6d.; Carnbroe, No. 1, 47s.; No. 3, 45s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1, 53s.; No. 3, 49s.; Calder, No. 1, 53s. 6d.; No. 3, 48s. 6d.; Summerlee and Coltness, No. 1, 56s. 6d.; No. 3, 51s.; Glengarnock at Ardrossan, No. 1, 54s. 6d.; No. 3, 49s. 6d.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Shotts at Leith, No. 1, 57s. 6d.; No. 3, 51s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 3019 tons, compared with 4333 in the corresponding period of last year. To Australia 370 were despatched, India 175, France 85, United States 30, South America 50, Italy 221, Germany 270, Holland 60, Belgium 90, Spain 45, other countries 210, the coastwise shipments being 1410, against 1595 tons in the same week of last year.

The market for malleable iron and steel now begins to exhibit a little more activity, the demand being better for home consumption as well as for export. Prices are still, however, in an uncertain state. In the course of the past week there was shipped from Glasgow locomotive engines and tenders to the value of £10,895, sewing machines £4913, other machinery £21,391, steel goods £5911, and miscellaneous iron goods £16,452.

There has been considerably more business during this week in the coal trade. Supplies are larger than they were last week, and still by reason of the extra demand, they are not much more than sufficient for the current wants. The blast furnaces and the malleable iron and steel works require large quantities, and shippers are now coming into the market. The downward course of prices has been arrested for the time, but so many miners are seeking employment that there is likely soon to be an ample supply of coals for all purposes.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THERE has been a slight lull in the coal trade during the last few days, followed by easier prices to the extent of 3d. per ton as compared with the figures of last week. On 'Change, Cardiff, there has been some discussion as to the cause of this and its probable duration. The likely cause, I think, is the boisterous weather of late, which has resulted in a good deal of damage to shipping and delayed the arrival of tonnage. Sidings at several of the large collieries are full, and managers are anxiously waiting to despatch some of the abundance—a question only of a few days.

One result of the "lull" is to retard the completion of contracts, as buyers will naturally think better terms can be obtained. I do not think that the figures quoted lately are likely to be altered. Any day an influx of shipping will send up prices or harden them. 11s. is the contract figure.

The P. and O. contract, to which I referred lately, and which should have been settled a fortnight ago, is still, I hear, hanging fire. From the present to the close of next month will be a period of anxiety to many coalowners. Once the usual large contracts are signed and sealed, a clear notion will be given of future trade.

I was in the old house coal district of Gellygaer this week, where a new company has been lately floated, and was impressed with the duration of this part of the coalfield. There are old workings there dating beyond the memory of man—one especially, in the district of Llanvabon. Thomas Powell, of the Gaer, the founder of Powell Duffryn, had his early successes at Gellygaer. Old and exhausted workings are to be seen, of course, but there is abundance of coal yet, and it is anticipated a big future awaits the district. The railway conveniences are very good.

I referred last week to the steady improvement going on in the import branch at the Bute Docks, Cardiff. In the matter of coal exports there is no cause for complaint, as the totals of the year will soon show. In imports there have not, up to late years, been a corresponding success; but careful nursing and persistent efforts have now begun to show good results—and it must be added, considerable expenditure has accompanied these efforts. Sir W. T. Lewis has directed this expenditure wisely, and given the fullest encouragement. As pointed out by a local contemporary, "the West Dock has been given up almost wholly to imports, and the East Dock largely taken up with this class of trade." The grain warehouses are large enough to store 26,000 tons; and the variety of commodities and manufactures is a striking one, from "excisable" articles to timber, joinery work, hardware goods, railway materials, moss litter, hay, straw, Dutch bulbs, and garden produce. The development of the import trade is in harmony with the great increase going on in the population of the large colliery districts of Wales.

There are several instances of dispute amongst the colliers, some of which have come before the authorities. An important case, tried this week at the Aberdare Police Court, was a charge against a number of hauliers by the Powell Duffryn Co. These had absented themselves from work without notice because the company would not pay for "shacklers" to fasten the horses to the trams. This was one of the simplest of duties and only taking a second or two of time, but the men would not yield, and the result was prosecution and conviction, each being fined £5 damages and costs. I give the particulars, as showing the character of this class of workman, and the difficulties coalowners have to contend with. As one of the audience in the court remarked, "they will strike some day because coalowners will not allow them boys to assist in driving."

The latest quotations, steam and house coal at Cardiff, are as follows:—Best steam, 11s. 6d. to 11s. 9d.; seconds, 11s.; dry coal, 9s. 9d. to 10s. 3d.; best Monmouthshire, 10s. 3d. to 10s. 6d. Small steam—now getting very plentiful—is being offered at 4s. 6d. to 5s. 3d., prompt shipment. House coal, which has dropped a little in sympathy with steam coal, is at 11s., best; No. 3, Rhondda, sells for 10s. 3d.; brush, 8s. 6d.; small, 6s. 9d.; No. 2, Rhondda, 8s. 9d.; through, 6s. 9d. to 7s.; small, 4s. 9d. to 5s. Most of these figures are capable of a slight reduction, if quantity is brought into consideration. Local trade remains to a great extent unaffected, prices moderately firm. One notable feature of the trade is, that efforts are being made to get a special class of North of England coals into Welsh districts in competition with Welsh coals. Circulars have been sent widely, describing coal and price delivered in Wales.

The iron and steel trades do not show any unusual degree of quality. All that can said is that the works are in moderate activity, some a shade better than others. I hear that contracts held are running out, and fresh ones are slowly coming to hand. This causes a certain amount of depression. Only one export of 50 tons rails has been noted for the week. Tin bars in fair quantities have been despatched, and in merchant iron and miscellaneous make a little better tone is to be recorded.

Cardiff Exchange quotations this week were:—Bessemer steel bars, £4; Siemens, £4 2s. 6d. to £4 5s.; steel rails, heavy, £3 12s. 6d. to £3 15s.; light, £4 10s. to £4 12s. 6d.

Swansea Exchange quotations indicated a tolerable steadiness. Glasgow pig, 42s. 4½d. cash; Middlesbrough, 35s. 6½d.; hematite, 43s. 4½d.; Welsh bars, £5 2s. 6d.; sheet iron at works, £6 to £6 10s.; steel rails, heavy, £3 15s. to £3 17s. 6d.; light, £4 10s. to £4 15s.; steel sheets, £6 5s. to £6 10s.; Bessemer bar, £4 to £4 2s. 6d.; Siemens the same. All delivered in district, cash less 2½ per cent. Tin-plate: Makers' quotations:—Bessemer cokes, 10s. to 10s. 3d.; Siemens, 10s. 3d. to 10s. 6d.; ternes, per double boxes, 28 by 20, 20s. to 24s. Best charcoal, 12s. to 12s. 3d. Wasters, 6d. to 1s. per box less than primes. Block tin is at £63 15s. to £63 17s. 6d. Copper, Chili bars, £40 7s. 6d. to £40 8s. 6d. Lead, English, £9 17s. 6d. to £10 2s. 6d.; Spanish, £9 16s. 3d. to £9 17s. 6d. Other Swansea quotations are:—Anthracite coal, 8s. 9d. to 12s. 6d.; cokes, 4s. 6d. to 4s. 9d. No. 3 Rhondda, 11s. to 12s. Cokes, furnace, from 12s.; foundry, from 17s. Patent fuel, 10s. 6d. to 11s. Pitwood, 17s. Iron ores, Tafna, 11s.; Rubio, 11s. 3d. to 12s.; ex ship, cash, 30 days.

At Cardiff, patent fuel was reported dull, price 11s. 6d. to 11s. 9d. Pitwood, falling demand; good wood selling at 15s. Coke inquiries, slack; prices unaltered, furnace at 15s. to 16s.; good foundry, 17s. to 17s. 6d. Special foundry, 21s.

It will be seen by the quotations that tin-plate has not made the expected spurt. The impression prevails that a change is at hand, and that it will be a marked one. The transition, however, will not be abrupt. Of late I have recorded the restart of mills which have been inactive. This has somewhat retarded the advance in price, as the increased demand has been met by an increased make. If the idle mills had remained idle, stocks would have fallen rapidly. Now the extra quantity sent from works has kept up stocks, and the result is a continuance of a fair trade without any "boom" about it. For instance, last week the exports were good, totalling 89.779 boxes from Swansea, and the make was equally good, 82,993 boxes, leaving stocks at 237,658 boxes. Tone of trade is hopeful, and a few weeks may see improvement.

The Government prosecution against officials of the Albion Colliery came to a conclusion at the close of last weeek at Pontypridd before the stipendiary, he holding that there was no case, and refusing to certify for a new hearing.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

A QUIET sort of business is still being transacted on the different iron markets over here, and the tendency of prices is more or less depressed. Both home and foreign requirements continue very small, makers, dealers, and consumers acting with caution.

There is as yet not the slightest symptom of an improvement to be noted in the various branches of the Silesian iron trade. Very few new consignments are in the market, and some of the blast furnace works complain of an entire absence of inquiry. The malleable iron business is in much the same condition, the majority of the mills being but indifferently engaged. List prices are only nominal as a rule, because there is scarcely any business to really test them, makers agreeing to the lowest quotations rather than lose a contract. The steel trade continues extremely dull, and there is also very little life stirring in the engineering department.

On the Austro-Hungarian iron market the general demand continues fair, but not brisk. A moderate degree of activity characterises the crude iron business on the whole, while the manufactured iron trade maintains a lively tone, although autumn business has developed more slowly and less favourably than was at first anticipated. The bar mills complain of an insufficient amount of new work coming in; while the plate and sheet trade continues quietly but altogether satisfactorily occupied. Girders and some special sorts of structural iron have been in very good call lately, but the quantities required are small generally, an order of some weight having not been booked for many weeks past. In Bohemia and Galicia the Upper Silesian works continue to offer iron at famine prices, which cannot fail to have a most depressing influence on the Austro-Hungarian iron business in general.

The production of brown coal in Austria is statistically stated to have been as under:—

| | 1893<br>100 kilogs. | 1892.<br>100 kilogs |
|---|---|---|
| Bohemia | 185,480 934 | 131,539,976 |
| Styria | 23,279,796 | 21,711,856 |
| Upper Austria | 3,719,179 | 3,631,346 |
| Carniola | 1,804,310 | 1,361,736 |
| Moravia | 1,188,562 | 1,110,215 |
| Istria | 900,085 | 868,883 |
| Carinthia | 753.326 | 810,753 |
| Dalmatia | 478,839 | 432,877 |
| Galicia | 366,900 | 192,609 |
| Tirol | 162,432 | 246,859 |
| Lower Austria | 19,704 | 16,147 |
| Silesia | 5,480 | 5,484 |
| Total output | 168,159,546 | 161,428,743 |

The accounts that are given of the general iron and steel trade in France continue of a cheering character. Current demand is reported to be good, that for plates and structural iron especially has been uncommonly lively, which led to a rising tendency in raw material. Prices are, for the present, without change, but there is a very firm tone noticeable all round, prospects for orders being good. Output of iron and steel in France was, for first two quarters of present year, as follows:—

| | 1894.<br>Tons. | 1893.<br>Tons |
|---|---|---|
| Forge pig | 818,988 | 762 859 |
| Foundry pig | 238,181 | 242,501 |
| Iron rails | 260 | 485 |
| Merchant bars | 360,870 | 357,618 |
| Iron plates | 53,202 | 56,304 |
| Steel rails | 97,060 | 117,804 |
| Steel rods, &c. | 152,493 | 141,641 |
| Steel plates | 78,678 | 58,265 |
| Hardware | 12,014 | 12,241 |

Rhenish-Westphalian iron business is still far from improving. All through last week there has been an exceedingly poor demand for both raw and manufactured iron; for the former article a continued weakness in prices must be noted, while in the manufactured iron branch a somewhat more steady tone is perceptible, although demand continues of the hand-to-mouth sort, and only small lots are generally required. Plates and sheets are in comparatively fair request, and so are girders. Export is languid and leaves no profit, at least so far as that to America is concerned.

The production of pig iron in the Saar and Mosel districts was, for September of the present year, in forge pig 26,642 t.; basic, 52,565 t.; foundry pig 10,483 t.; together, 89,689 t. Production was less by 2·7 per cent. during the preceding month of August, when it amounted to 92,219 t. In September, 1893, the total production was 81,526 t., which shows an increase of 10 per cent. for the same month of present year.

The collieries of the Saar district have yielded in September, within twenty-five working days, 560,060 t., and sold 571,890 t. In August 563,780 t. were produced within twenty-seven days, and consumption was 566,610 t. only, while in September of last year 529,563 t. were produced, and 552,735 t. were sold.

THE PANAMA CANAL.—The new Panama Canal Company was legally constituted at the meeting of shareholders held on Saturday afternoon. MM. Baillet, Brolemann, Carraby, Chanove, Jonquières, Lebegue, Ramet, St. Puentin, and Souchin were appointed administrators for six years, while MM. Barbier, Lemoine, and Fougen were named commissaries. Before closing the sitting, M. Lemarquis, the legal representative of the old bondholders, who presided, announced that a cablegram would be at once sent to M. Mancini, at Bogota, who would on its reception announce the constitution of the new company to the Colombian Foreign Minister, and that on Sunday 800 workmen would resume the so-long-abandoned work of the Culebra Cutting. Though the list of administrators proposed by M. Lemarquis was adopted unaltered by an overwhelming majority of the shareholders, the meeting was very tumultuous. M. Thiebaud protested against the constitution of the new company, and declared that the proposed new administrators were the representatives of the men who had ruined the old Panama Company. The proposed new administrators represented MM. Eiffel, who subscribed ten million francs; Hugo Oberndoerffer, who subscribed three million five hundred thousand francs; Buno Varilla, who subscribed two million two hundred thousand francs; the administrators of the old company, who subscribed eight million francs; and the credit establishment, which subscribed ten million francs. With such persons at the head of the enterprise, it would be useless to hope the public would subscribe the remaining five hundred million francs required to complete the canal. M. Thiebaud's remarks were received rather coldly, and did not prevent the list of administrators prepared by M. Lemarquis from being adopted almost unanimously.

## LAUNCHES AND TRIAL TRIPS.

Last week Messrs. Lobnitz and Co., Renfrew, launched the twin screw hopper dredger St. Martin, which they have built to the order of the British Admiralty. She will be capable of working to a depth of 46ft.

On October 22nd Messrs. Wm. Simons and Co. launched from their yard at Renfrew, complete, with its dredging and propelling machinery on board, the twin screw hopper dredger St. Enoch. This vessel is built to the order of the British Admiralty, and is a duplicate of the St. Alban, which has just been started to work at Portsmouth. It is designed to dredge and discharge clay of a very adhesive nature, and is capable of working to a depth of 46ft. under water. At the launch there were present Messrs. Painter, Parker, and Scroggins, her Majesty's Surveyors, under whose supervision the vessel has been built.

Messrs. Blackwood and Gordon, engineers and shipbuilders, Port Glasgow, have at present in hand a new screw steamer for the City of Dublin Steam Packet Company, of Dublin, for its Dublin and Liverpool trade, a duplicate of the steamer Louth, lately built by them, and which vessel has given the utmost satisfaction to her owners, as well as to the cattle dealers and the general travelling public. The new steamer will have a number of improvements made on the Louth's design with the view of obtaining increased speed and economy in working. The builders are pressing forward the work for the new vessel so as to ensure speedy delivery, and we have no doubt that the Dublin people will be well pleased to see a duplicate Louth in the cross channel trade at an early date.

On the 19th inst., at twelve o'clock, the Tyrone, the third canal lighter built for the Ulster Steam Lighter Company within the short period of about a year, was launched from the yard of Mr. Denis Crawford, Newry. The new boat will carry 72 tons of cargo. She will be fitted with patent adjustable twin propellers, the invention of Mr. Henry Barcroft, D.L. This propelling gear is now being manufactured by Messrs. Robey and Co., of Lincoln. The compound engines will in this instance be supplied by Messrs. Cochrane, of Birkenhead. She will be furnished with a patent heater, by Royle, of Manchester, which will heat the feed-water on its way to the boiler, which will have a pressure of 120 lb. This, it is expected, will effect a considerable economy in coal. The previous experience of the company furnishes data on the head of coal consumption which gives every evidence that the boat will run to Belfast and back—a distance by water of 130 miles—carrying cargo both ways, on a consumption of about 30 cwt. of Welsh coal. The entire weight of engine, boiler, &c., will be 55 cwt., and as the machinery is on deck, all space underneath is available for the cargo.

## MONEY OF THE WORLD.

Mr. Preston, Acting Director of the United States Mint, has prepared a table of the monetary systems of the world. The table shows that the aggregate stock of gold is 3,582,005,000 dols.; silver, 4,042,700,000 dols.; uncovered paper, 2,635,873,000 dols.

Stock of gold possessed by principal countries is as follows: United States, 604,000,000 dols.; Great Britain, 550,000,000 dols.; France, 900,000,000 dols.; Germany, 600,000,000 dols.; Russia, 250,000,000 dols. The stock of silver is as follows: United States, 615,000,000 dols.; Great Britain, 100,000,000 dols.; France, 700,000.000 dols.; Germany, 211,000,000 dols.; Russia, 60,000,000 dols.

The stock of silver is divided as follows: United States, 538,000,000 dols. full tender, 77,000,000 dols. limited tender; Great Britain, no silver full tender, 100,000,000 dols. limited tender; France, 650,000,000 dols. full tender, 50,000,000 dols. limited tender; Germany, 103,000,000 dols. full tender, 108,000,000 dols. limited tender; Russia, 25,000,000 dols. full tender, 38,000,000 limited tender.

The ratio prevailing in nearly all principal countries between gold and legal tender silver is 1 to 15½. The ratio between gold and limited silver is, as a rule, 1 to 14·38. The respective ratios in the United States are 1 to 15 98 and 1 to 14·95.

The various monetary systems as divided among countries: Gold and silver: United States, France, Belgium, Italy, Switzerland, Greece, Spain, Netherlands, Turkey, and Japan. Gold: United Kingdom, Germany, Portugal, Austria, Scandinavian union, Australia, Egypt, Canada, and Cuba. Silver: Russia, Mexico, Central and South America, and India. Of the uncovered money South America has 600,000,000 dols.; Russia, 500,000,000 dols.; United States, 412,000,000 dols.; Austria, 260,000,000 dols.; Italy, 153,000,000 dols.; Germany, 107,000,000 dols.; France, 81,000,000 dols.; and Great Britain, 60,000,000 dols.

The per capita circulation of gold is: United States, 9·01 dols.; United Kingdom, 14·47 dols.; France, 20·52 dols.: Germany, 12·12 dols.; Russia, 2·21 dols. Per capita of all classes of money is: France, 40·56 dols.; Cuba, 31 dols.; Netherlands, 28·88 dols.; Australia, 26·75 dols.; Belgium, 25·52 dols.; United States, 24·34 dols.; United Kingdom, 13·42 dols., and Russia, 7·16 dols.

The following figures indicate the relative powers, as they are estimated by some of our friends across the Channel, possessed by various kinds of fuel for converting water into steam:—One kilogramme of wood converts into steam 3·4 kilogrammes of water; one kilogramme of brown coal, 3·5 to 4·9 kilogrammes of water; one kilogramme of cut peat, 2·8 to 4 kilogrammes of water; one kilogramme of machine peat, 4·5 to 5 kilogrammes of water; one kilogramme of hard coal, 7 to 8 kilogrammes of water; one kilogramme of medium coal, 6 to 7 kilogrammes of water; one kilogramme of poor coal, 4 to 6 kilogrammes of water. It is estimated, on an average, that 100 pounds of peat are equal, in respect to the really available heating capacity, to 50 to 60 pounds of hard coal.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

10*th October*, 1894.

19,245. Watch Stands, F. H. Davidson, Manchester.
19,246. Straps for Raising Windows, J. C. Craine, Manchester.
19,247. Electrical Ceiling Roses, G. F. Kenyon and E. Moorhouse, London.
19,248. Bicycles, J. Hargreaves, London.
19,249. Manufacture of Blankets, W. Edwards, London.
19,250. Horseshoe, W. Chapman, London.
19,251. Separation of Mineral Slimes, G. H. Lloyd, London.
19,252. Concentrating, &c., Minerals, G. H. Lloyd, London.
19,253. Lifebuoy, J. M. Richards, London.
19,254. Pneumatic Tires for Cycles, A. Wadham, London.
19,255. Water Heaters, A. J. Boult.—(*C. H. Fuchs, Germany.*)
19,256. Pedal for Bicycles, W. P. Thompson.—(*The firm of Frankenburger and Ottenstein, Germany.*)
19,257. Washing Syphons, &c., G. A. Merchant, Liverpool.
19,258. India-rubber Balls, W. P. Thompson.—(*E. Meyer, Germany.*)
19,259. Machines for Cleaning Knives, M. W. Wright, London.
19,260. Fork Bearing for Bicycles, F. Rough, Hereford.
19,261. New Clip or Fastener, E. J. Wagner, London.
19,262. Jointing Staves of Casks, J. W. and T. G. Lahey, London
19,263. Recovering Used Solvents, G. Braun, London.
19,264. Air-ships, R. E. May, London.
19,265. Means of Signalling on Railways, L. G. Tate, London.
19,266. Window Ticket Hook and Clip, W. Potter, London.
19,267. Pumping Engines, &c., J. D. Wardale, London.
19,268. Governing Engines, W. Goodbrand and T. R. Wollaston, Manchester.
19,269. Steam and Water Separator, J. E. Sweet, London.
19,270. Shoe-fastener, I. D. Wright, London.
19,271. Construction of Billiard Tables, J. S. Burroughes, London.
19,272. Rotary Steam Engine, J. N. Hartzell, London.
19,273. Cleats for Ropes, C. A. McEvoy and T. Webster, London.
19,274. Expansion Gear for Engines, H. O. Beckh, London.
19,275. Braces, F. Cade, London.
19,276. Anchors, W. and J. Herbert, and E. Grahame, London.
19,277. Securing Stoppers in Jars, F. E. Hollyer, London.
19,278. Velocipedes, J. Bradbury, jun., London.
19,279. Heating Railway Carriages, R. T. Preston, London.
19,280. Producing Illusory Effects, G. D'Arc, London.
19,281. Printing or Gilding Machines, E. H. Schmidt, London.
19,282. Paint Brushes, A. T. Butchard, London.
19,283. Self-winding Clocks, A. G. Wiseman, London.
19,284. Furnaces of Marine Boilers, D. J. Morgan, London.
19,285. Electric Chandeliers, M. V. Luis and E. C. Elgood.—(*L. Priebe, Germany.*)
19,286. Electric Motor Appliances, L. B. Atkinson, London.

11*th October*, 1894.

19,287. Tilting Casks, C. Green, jun., and H. T. Wood, London.
19,288. Cycle Brake, A. Rainsford, Birmingham.
19,289. Hair Curler or Waver, T. P. Batkin, Birmingham.
19,290. Pulverisers, J. P. Griffiths, Dudley.
19,291. Electric Signal, D. F. Adamson and C. D. Hutchins, London.
19,292. Carding Engines, C. Whitworth and A. S. Mills, Heywood.
19,293. Retort Mouthpieces, J. L. and T. J. L. Mitton, Huddersfield.
19,294. Tip for Billiard Cues, E. H. Russell, Wallasey, Cheshire.
19,295. Toasting Appliance, A. E. Dinsmore, Liverpool.
19,296. Kitchen Ranges, J. W. Dobson, Keighley.
19,297. Egg Beating Apparatus, J. and A. T. Dewar, Liverpool.
19,298. Knitting Machines, J. H. Smith and F. W. Pare, Nottingham.
19,299. Smokeless Explosives, G. Hübner, Manchester.
19,300. Breech-loading Small Arms, S. Mills, Birmingham.
19,301. Preventing Accidents to Platelayers, A. Machin, Glasgow.
19,302. Apparatus for Fastening Envelopes, F. C. Lynde, Manchester.
19,303. Fire-bricks for Heating Steel, W. Hammond, Pott Shrigley.
19,304. Felloe for Wheels, H. Hollick, Coventry.
19,305. Brake Apparatus for Cycles, P. Weir, Bristol.
19,306. Pressure on Nip-rollers, J. H. Whitehead and W. E. Layland, Halifax.
19,307. Noble's Comb, J. H. Whitehead and J. Lister, Halifax.
19,308. Drafting Patterns, M. Knowles, Halifax.
19,309. Phosphate Food for Horses, T. T. Chard, Bristol.
19,310. Cycle Saddles, G. Salter, Birmingham.
19,311. Device for Heating Rooms, J. Cinnamon, Glasgow.
19,312. Case for Protecting Maps, W. Brierley.—(*The Firm of Bial, Freund, and Co., Germany.*)
19,313. Appliances for Recording Distances, J. B. Howard.—(*K. Keyssner and E. Hessdorfer, Germany.*)
19,314. Cycles, A. Jennings, Glasgow.
19,315. Stopping Leaks in Ships, W. Adams, Dartmouth.
19,316. Cycles, H. W. Ashby and R. Lindsay, Dublin.
19,317. Safety Trivet, T. L. Poidevin, Gurnsey.
19,318. Station Indicator, W. Ross and P. Tickle, St. Helen's.
19,319. Weather Bars for Doors, A. H. Williams, London.
19,320. Target, B. L. King, London.
19,321. Automatic Weighing-machines, J. H. Robinson, London.
19,322. Cabinets, A., A. jun., and J. S. Thomson, London.
19,323. Drawing-pins, B. Madoc, London.
19,324. Portable Hothouse, H. Courteen, London.
19,325. Fireproof Floors, T. R. W. Mossman, London.
19,326. Sash Fasteners, W. Fletcher and J. Tatham, London.
19,327. Construction of Navigable Vessels, H. F. Swan, London.
19,328. Automatic Mouse Trap, H. Coleman and F. Plaister, London.
19,329. Photographic Shutter, A. C. Jackson, London.
19,330. Apparatus for Delivering Coal, R. Cowie and Messrs. Dixon and Mann, Glasgow.
19,331. Opening Window-sashes, A. R. Austin, Glasgow.
19,332. Washing-machine, R. P. Gillon, Glasgow.
19,333. Tobacco Pipes, L. E. G. de Woolfson and E. Smith, Shrewsbury.
19,334. Driving-gear for Cycles, A. Jordan, London.
19,335. Hay-tedders, A. J. Boult.—(*C. H. Teicher, Germany.*)
19,336. Supporting Device for Pants, D. C. Fraser, London.
19,337. Ships' Rudders, P. A. Mensing, Liverpool.
19,338. Preparation of Yeast, W. G. Johnston and J. F. Warwick, London.
19,339. Couplings, K. Reyscher, London.
19,340. Preservation of Milk, R. G. Nash, London.
19,341. Oil Cans, B. H. Chameroy, London.
19,342. Production of Anilides, L. Lederer, London.
19,343. Oil Motor Engines, C. D. Abel.—(*The Gusmotoren Fabrik Deutz, Germany.*)
19,344. Vent Device for use with Beer Casks, J. Clemson, London.
19,345. Indicating Rotation Speed, M. S. Napier, London.
19,346. Pneumatic Tires, A. Wadham, Lonnon.
19,347. Packing Drinking Glasses, G. and E. Scott, London.
19,348. Shampooing Shield, A. F. Godefroy, London.
19,349. Combined Writing-desk and Type-writer, L. H. Dodge, London.
19,350. Extracting Heated Air from Cases, J. M. Sykes, London.
19,351. Turkish Bath, G. Hughes.—(*G. M. Sternkopf, Germany.*)
19,352. Leaden Pipes, C. and S. Constanduros, London.
19,353. Safety Stirrups, T. J. Dancer, London.
18,354. Paper Binding Machines, E. T. Greenfield, London.
19,355. Post-marking Machines, M. V. B. Ethridge and H. E. Waite, London.
19,356. Bags, H. Lewis, London.
19,357. Window Sash Fastener, P. R. J. Willis.—(*N. Johnson, United States.*)
19,358. Pneumatic Saddle Pad, J. Korbuly, London.
19,359. Making Plated Catgut Strings, P. Stark, London.
19,360. Nail, Pins, Screws, &c., G. C. Warden, jun., London.
19,361. Golf Clubs, W. T. Jennings, London.
19,362. Electrical Safety Devices, J. S. Raworth, London.
19,363. Anti-corrosive Composition, G. Rockliffe, London.
19,364. Electro-motors, C. Connors and W. L. Davies, London.
19,365. Window Catches or Sash Fasteners, W. Blair, London.
19,366. Safety Riding Skirts, E. J. Wagner, London.
19,367. Billiard Cue, I. Davis, London.

12*th October*, 1894.

19,368. Construction of Poison Bottles, W. Gibbin, jun., London.
19,369. Swimming Pads, F. W. Hoar, Southampton.
19,370. Safety Blouse Pin, A. Prym, London.
19,371. Pneumatic Tire Grip Pump, J. Slaughter, jun., Coventry.
19,372. Heald Machine, T. Blackhurst and T. Roberts, Darwen.
19,373. Detachable Pneumatic Tire, S. J. Rose, Witney.
19,374. Means for Sharpening Saws, W. E. Plested, Watford.
19,375. Valve for Water Ballast Tanks, J. Rowland, Sunderland.
19,376. Combination Collar Studs, T. Morton, Birmingham.
19,377. Cuff Links, T. Morton, Birmingham.
19,378. Doors of Railway Carriages, J. Bennison, Manchester.
19,379. Clothing Card Flats, G. P. Appleyard and L. P. Foster, Halifax.
19,380. Wheels for Vehicles, A. Hodgkinson, Manchester.
19,381. Cleansing Calico Printers' Blanketing, W. Hadfield, J. J. Sumner, and H. Hadfield, Manchester.
19,382. Flower-beds, F. Pesson, Manchester.
19,383. Feed-water Heaters, R. H. Turner and J. Whiteley, Manchester.
19,384. Weighing Machine for Grain, W. R. Baxter, London.
19,385. Suspension Lamp Hangers, T. Smith, London.
19,386. Cigarettes, G. C. Dixon, London.
19,387. Magnetic Shielding, G. F. FitzGerald, Dublin.
19,388. Printing Cotton Fabrics, W. E. Kay and the Thornliebank Company, Manchester.
19,389. Artificial Teeth, R. Marston and J. Parr, Leicester.
19,390. Drawing Instruments, A. A. Woodward, Birmingham.
19,391. Dust-pans, A. Paget, Loughborough.
19,392. Candlesticks, G. H. Rose, Bedford.
19,393. Telescope Tube for Exhibiting Chrysanthemums, J. Stiles, Teignmouth.
19,394. Utilisation of Purple Ore, T. Twynam, Surrey.
19,395. Fixing Rims or Felloes on Wheels, H. Hollick, Coventry.
19,396. Kilns for Burning Limestone, H. Parry, Liverpool.
19,397. Slipper Brake, &c., for Road Vehicles, C. H. Bennett, Sheffield.
19,398. Tap for Measuring Spirits, &c , L. F. Shove, Bristol.
19,399. Bead-threading Machinery, L. Myers and C. B. Ketley, Birmingham.
19,400. Connecting-link for Chain Cables, W. H. Simon, Birmingham.
19,401. "Square Motion" Combining Machines, T. W. Harding, Leeds.
19,402. Combination Framework Fire-light, J. F. Kempe and M. A. Eslick, Liverpool.
19,403. Production of Letters for Signs, A. Harris, Birmingham.
19,404. Potato Digger, D. Smith and T. H. Tilley, London.
19,405. Wrought Iron Pulleys, A. L. Schmidt, Germany.
19,406. Shovel with Rake Attachment, J. R. Parker, London.
19,407. Bird Cages, F. Baker, Birmingham.
19,408. Steam Brakes of Locomotives, W. H. Flitcroft, London.
19,409. Assisted Draught for Steam Boilers, J. W. Claridge, London.
19,410. Hook with Spring, B. F. Bryant, Ramsgate.
19,411. Fastening Tubing to a Nozzle, L. N. Fowler and W. C. Nangle, London.
19,412. Advertising by Post-cards, H. G. Maxwell and E. D. Richards, London.
19,413. Filter for Water Cisterns, A. W. Baylis, London.
19,414. Casket for Containing Photography, A. Murray, Dundee.
19,415. Rims for Wheels, F. Bowden.—(*A. C. Fairbanks, United States.*)
19,416. Cycles, E. J. Newell, J. Hodson, and J. P. Nicholson, London.
19,417. Changing Action for Cameras, A. E. Staley, London.
19,418. Velocipedes, B. Fort and C. Anderson, Liverpool.
19,419. Wheels, W. Fish, London.
19,420. Colouring Matter, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
19,421. Hauling by Electricity, &c., F. B. Behr, London.
19,422. Barrel Tilter, D. Bale and T. B. Evans, Cardiff.
19,423. Retorts for Production of Gas, J. H. Dunn, London.
19,424. Signal for Railway Guards, W. Vogeler and J. Seitz, Cologne.
19,425. Spurs, R. Ostermann, Cologne.
19,426. Trestles, J. Steinfeld and T. Becker, Cologne.
19,427. Apparatus for Dyeing Skins, R. Ergang, London.
19,428. Tubular Frames for Cycles, O. Schlick, London.
19,429. Rendering Goods Uninflammable, A. E. Webb, London.
19,430. Taps, F. Cobham, London.
19,431. Cork-grinding Machinery, J. B. Morrison, Glasgow.
19,432. Lamps, J. McAllister, Glasgow.
19,433. Engine Packing, H. S. Pringle and J. Jordan, London.
19,434. Preventing Breaking of Ropes, F. Shepherd, London.
19,435. Railway Carriage Lamps, F. Semmence, London.
19,436. Bicycles, &c., F. Sulley and W. E. Dowson, London.
19,437. Treatment of Terra-cotta, &c., E. Tortora, London.
19,438. Velocipedes, F. J. Endrès, London.
19,439. Cabinet Folding Bedstead, G. Willmot, London.
19,440. Skates, W. Harvey, London.
19,441. Paper Fastener and Ticket Holder, S. H. Crocker, London.
19,442. Collapsible Baskets and Boxes, J. Dobson, London.
19,443. Electrical Production of Music, P. T. Letchford, London.
19,444. Arc Lamps, G. G. Stout, London.
19,445. Turning Leaves of Music, B. F. Wallace, R. T. Proctor, and W. R. Hall, London.

13*th October*, 1894.

19,446. Boiler-cleaning Machine, T. Cudlipp, London.
19,447. Stair Protector, J. W. W. York and G. Whittle, Leicester.
19,448. Fire-escapes, G. M. Dudley, Dublin.
19,449. Gate-bottom, M. Lee and D. Davies, Llanelly.
19,450. A Catch for Fishing-rod Joints, M. J. Boyle, Cavan.
19,451. Bungs for Casks, R. D. Bailey, London.
19,452. Manufacture of Confections, R. J. Harrison, Belfast.
19.453. Lifts, F. Rawnsley, Halifax.
19,454. Theodolites, C. Merrick, Bristol.
19,455. Flushing Cisterns, T. S., W. and B. Stock, H. W. and T. L. Taylor and T. Shingleton, Birmingham.
19,456. Removable Terminals, J. H. Cartland, Birmingham.
19,457. Purification of Coal, T. Clapham and J. Laycock, Keighley.
19,458. Spindles, B. A. Dobson and E. Gillow, Manchester.
19,459. Sinking and Walling Scaffolds, H. Joyner, Barnsley.
19,460. Show Stands, G. A. Thomas, Bristol.
19,461. Sliding Rods of Chandeliers, R. H. Best, Birmingham.
19,462. Incandescent Gas Burners, F. E. Nichol, Portobello.
19,463. Separating Wool Washing Liquors, R. B. Gow, Glasgow.
19,464. Wheel with Elastic Tire, A. Metzger, Berlin.
19,465. Handkerchiefs, A. J. Pullman, Glasgow.
19,466. Screw Thread Dies, E. Beckitt, J. Rankin, and J. K. White, Glasgow.
19,467. Bottles or Vessels for Liquids, H. Rocholl, Dundee.
19,468. Delver or Digger, J. Morris, Kenyon, near Manchester
19,469. Blacking, J. Noad, London.
19,470. Valves for Steam Engines, C. W. Thompson, London.
19,471. Valves for Steam Engines, C. W. Thompson, London.
19,472. Cornice Ring Roller, R. J. Gibson, London.
19,473. Turning Leaves of Books, A. J. Boult.—(*O. Jäntsch, ——*)
19,474. Trunks and Boxes, &c., N. M. Bateson, Liverpool.
19,475. Stays, S. Herrmann, London.
19,476. Footballs, H. D. Hodgkinson and J. Cooper, London.
19,477. Boots, F. Schoelles, Manchester.
19,478. Treatment of Ores, H. F. Kirkpatrick-Picard, London.
19,479. Supplying Water to Hydraulic Lifts, J. C. Etchells, Manchester.
19,480. Buttons, C. F. Püschner and F. Püschner, London.
19,481. Heating Water by Electricity, J. W. Ewart, London.
19,482. Construction of Filter Beds, H. L. Hinnell, London.
19.483. Letters for Shop Fronts, &c., A. Standring, Manchester.
19,484. Clothing Clip for Bicyclists, J. M. Gillies, Dublin.
19,485. Treatment of Textile Fabrics, A. F. B. Gomess, London.
19,486. Device for Handling Cake, A. G. Stevens, London.
19,487. Lifts, F. T. Long, London.
19,488. Obtaining Salt, T. Scott and the Patent Salt Company, Glasgow.
19,489. Curling Hair, W. W. Twigg and F. R. Baker, Birmingham.
19,490. Guard Attachments for Doors, W. A. Thornton, London.
19,491. Sanitary Slop Receptacle, J. J. Feldman, London.
19,492. Wooden Blocks for Children, W. H. Drinkwater, London.
19,493. Safety Lamps for Mines, T. Coad, London.
19,494. Weighing Machines, D. Bacas-y-Montero, London.
19,495. Stoppers for Bottles, H. E. G. Earle, London.
19,496. Spectral Signals, J. Munro, Croydon.
19,497. Spray Nozzle, H. F. Neumeyer, London.
19,498. Puzzle, H. Hill, London.
19,499. Stand for Feed-bags, H. Bailey and W. Patterson, London.
19,500. Motors for Tramcars, &c., R. M. Macdonald, London.
19,501. Drawing Square, C. Hanke, London.
19,502. Marker for Cards, B. E. Edwards, London.
19,503. Folding Tables, J. W. Lyon, London.
19,504. Book-racks, J. W. Lyon, London.
19,505. Cycles, B. Endler, London.
19,506. Metallic Packing for Piston Rods, G. W. Manuel, London.
19,507. Cycle Spanner, G. W. and C. B. McIntyre, London.
19,508. Cut-outs for use in Electric Circuits, C. P. C. Cummins and J. L. Golding, London.
19,509. Photographic Objectives, P. Rudolph, London.
19,510. Alloy of Aluminium, H. G. Partin, London.
19,511. Conveying Paper through Printing-machines, W. Reader, London.
19,512. Curtain Rods and Brackets, J. R. Endean, London.
19,513. Dress Suspender, S. A. Cole, London.
19,514. Bicycle and Vehicle Wheels, G. E. Butcher, London.
19,515. Diffusing Light, C. Jousset and F. R. Boardman, London.
19,516. Mowing Machine, C. Stoldt and W. Spiess, London.
19,517. Indicating Electric Lamp Hours, R. Wende, London.

19,518. Rail Joints, R. H. Pierce, London.

19,519. Manufacture of Quill Tubes, R. Zeise, London.

19,520. Furnaces, A. F. A. Kinaux, London.

19 521. Indicating Quantities of Liquids, G. Price and G. J. J. Legrand, London.

19,522. District Telegraph Calls, W. H. Garven, London.

19,523. Tires and Rims of Cycles, J. H. Barry, London.

19,524. Cartridge-feed Apparatus, J. G. Accles, London.

19 525. Utilisation of Waste Materials, J. H. Barry, London.

*15th October*, 1894.

19,526 Manufacture of Tooth Brushes, W. Hawtin, London.

19 527. Producing Torpedo Rotation, T. Renville, London.

19,528. Bicycles, O. G. Gümpel, London.

19 529 Heat Non-conductor, G. C. Douglas.—(*W. Don and T. Watson, India.*)

19,530. Cranks for Cycles, G. Pirnie, Dundee.

19 531. Stair Treads, E. Nuttall and T. Oddy, Rochdale.

19 532. Combs, J., G., S., and J. Ambler, jun., and J. Shackleton, Bradford.

19 533. Accouchement Pulleys, C. and C Green, jun., London.

19,534. Sanitary Pipes and Joints, &c , J. Tuke Leeds

19 535. Varnish for Colours, T. Coppock, jun., Manchester.

19 536. Cycles, A. Maltby, London.

19 537. Automatic Coin-freed Machine, W. Edwards, London.

19 538. Sliding Sashes, C. Milne and R. Barton, Glasgow.

19 539. Hat Bands, F. W. and B. Franklin and P. E. Taylor, Birmingham.

19,540. Balling Wool, T. H. Wharton and H. Monies, Bradford.

19,541. Securing Clothing, J. and J. Vaughan and T. Houghton, Ashton-under-Lyne

19 542 Brooches and Bracelets, &c., E. Hulme, jun., Manchester

19,543. Stoppers, F. A Bird and J. B. Fenby, Castle Bromwich.

19 544 Walking-stick and Pipe Case, S. Kenyon, Doncaster.

19,545. Field Cooking Apparatus, R. Crudass, Aldershot.

19 546 Sounding Device, W. Aldred and W. Bradley, Sheffield.

19,547. Fixing Labels to Umbrellas, W. Corah, jun., Birmingham.

19,548. Automatic Egg Cooker, &c , C. Trewartha, Exeter.

19 549. Apparatus for Drying Bricks, A. Lilley, Newcastle-on-Tyne.

19 550. Shuttle Guards, H. Rhodes and G. Thornley, Manchester.

19 551. Weaving Inner Selvedges, E. T. Whitelow, Manchester.

19 552. Tire, W. Lowe, Manchester.

19,553. Sash Fasteners, H. R. Harvey and J. W. B. Unwin, Croydon.

19,554. Self-closing Doors, W. W. Burland, Stockton-on-Tees.

19 555. Concentrator, W. and B. Howard and C. A. Bleyl, London.

19,556. Envelope, Note, and Blotting Paper, R. Eaton, Leeds.

19 557. Valve for Pneumatic Tires, &c., T. G. Jelly, Birmingham.

19,558. Safety Apparatus for Cages, D. Brauckmann, Cologne.

19,559. Tobacco Pipes, J. W. Priestley, Bradford.

19,560. Transmitting Power from Engines, F. Royce, Manchester.

19,561. Mouthpiece, A. and A. Mokaiesh and J. S. Shepherd, Manchester.

19,562. Digging Machines, T. Haslam and P. Mawdsley, Liverpool.

19,563. Ruling Pens, F. H Batters, Liverpool.

19,564. Cycle Brake and Mudguard, S. Bramall London.

19,565. Turning Irregular Forms, W. A. Robertson, London.

19,566. Lamps for Burning Mineral Oils, R. Thompson, London.

19,567. Clips for Holding Letters, W. Higgs, H. P. Clemetson, and C. W. Higgs, London.

19,568. Driving Gear of Bicycles, R. Corsham, London.

19,569. Beam Attachment for Hatchways, E. Bond, London.

19,570. Form of Station Pointers, J. F. Stuart, London.

19,571. Anti-shoe-slip, G. S. W. Gillingwater, London.

19,572. Type-writing Machines, North's Type-writer Manufacturing Company, Limited, and M. Donne, London.

19,573. Scarf Retainer, W. Nicholls, London.

19,574. Sliding Sash Boxed Frames, W. Youlten, London.

19,575. Pockets for Ladies' Dresses, W. Hopekirk and E. Graham, London.

19,576. Machinery for Moulding Bricks, &c., J. W. Craven, London.

19,577. Alarms for Velocipedes, &c , E. W. Dickins, London.

19,578. Regulating the Supply of Lubricating Oil, W. R. Chester, London.

19,579. Manufacture of Wheel Rims, R. F. Hall, London.

19,580. Fire-proof and Weather-proof Materials, C. Williams, London.

19,581. Cream Separators, A. Krank, London.

19,582. Fastenings of Shirt Cuffs, C. E. Solomon, London.

19,583. Machines for Bottling Beer, T. Sutcliffe, London.

19,584. Pneumatic Quick-firing Guns, T. W. Just, London.

19,585. Arc Lamps, P. A. Mougin, London.

19,586. Keyboard Musical Instruments, F. Hanke, London.

19,587. Shelves, H. E. Davidson. —(*D. E. Hunter, United States* )

19,588. Oil-cups and Lubricators, E. Warwick, Birmingham.

19,589. Gas Engines, D. Davy, London.

19,590. Fuel Economiser for Ranges, J. P. Harding, London.

19 591. Paper Fasteners, R. M. Pancoast, London.

19,592. Heating Apparatus, H. E. Newton.—(*R. N. Oakman, jun., United States.*)

19,593. Pessaries, O. Ahlswede, London.

19,594. Filter, H. Crot, London.

19,595. Means for Trimming Lamp Wicks, P. Sharpe, London.

19,596. Marine Propeller Shafts, D. B. Morison, London.

19,597. Gauge, C. A. Dart, London.

19,598. Combination Turkish Bath, H. Nunnerley, London.

19,599. Cutting Apparatus, E. and R. Cornely, London.

19,600. Clip, O. C. Mootham, London.

19,601. Forks, T. Jones, London.

19,602. Stopping and Starting Road Vehicles, C. D. Vaughan, London.

*16th October*, 1894.

19,603. Electrical Fittings, C. L. Clarke and W. P. Theermann, Manchester.

19,604. Non-slipping Tire for Vehicles, J. R. Jackson, Manchester.

19 605. Electrical Conductors, &c , B. Andrews, London.

19,606. Submarine Torpedo Boat, S. and G. Rogers, Brighton.

19,607. Fire Tidy, S. J. Cockshaw, Huddersfield.

19,608. Drawing Rolls, A. G. Brookes.—(*W. Hinchliffe, United States.*)

19,609. Cushions for Furniture, A. G. Brookes.—(*W. Vogler, United States* )

19 610. Feed-water Heaters for Boilers, K. Lupton, Coventry.

19,611. Dissolvers for Optical Lanterns, W. H. Foulds, Glasgow.

19,612. Attaching Handles to Knitting Pins, G. Lewis, Redditch.

19,613. Bed-warmer, I. Stanton and W. Simmons, Wolverhampton.

19,614. Drawing Frames, C. Butterworth and J. Bowker, Hollinwood.

19 615. Ships' Berths, J. Duggan and W. Harley, Liverpool.

19 616 Umbrellas and Parasols, A. and W. Hill, Bristol.

19,617. Bedsteads, A. Rathbone and S. Taylor, Manchester.

19,618. Securing Terminals to Rods, W. H. Richards, Birmingham.

19,619. Cutting Machines, H. A. Oldershaw, Leicester.

19 620. Manufacture of Shirts, L Cox, Birmingham.

19,621. Hydraulic Pumping Apparatus, A. B. Brown, Glasgow.

19,622. Smoking Pipes, W. Warburton, Sheffield.

19,623. Adjustable Spanners, A. A. Allcard, Sheffield.

19,624. Chimney Cowls, E. Handslip, J. Grinton, and T. Christie, Newcastle-on-Tyne

19 625. Transparent Office Ruler, H. P. Ringwood, Dublin

19,626. Type Beds of Printing Machines, R. C. Annand, South Shields.

19,627. Washing Machine, T. Cudlipp, London.

19,628. Ascension Filter, F. Todd, Spalding.

19,629. Washing add Steaming Casks, P. Robinson, Birmingham.

19,630 Securing Purses, &c , D. I. Marcuson, Birmingham.

19,631. Rack for Photographic Negatives, J. B. Brooks, Birmingham.

19 632. Tongs for Lifting Hot Blooms, T. Williamson, Glasgow.

19,633. Cap Badges, C. F. Gaunt, Birmingham.

19 634. An Improved Ring, F. A. Ludlow, Birmingham.

19 635. Water Meters, L. H Nash, Liverpool

19,636. Covering Water Pipes, &c., J. A. Fisher, London.

19,637. Lighter for Pipes, Cigars, &c., A G. Lee, London.

19 638 Curling Hair, H. McClelland and F. G Baker, Birmingham.

19,639. A Drawer Cabinet, J. Young and F. J. Young, London.

19 640. Removing Foreign Matters from Roots, C. R Orr, London.

19 641. Wheel Tires, C. H. Gray, London

19,642. Feed-water Injectors, W. P. Thompson.—(*P. P. Hogue and H. G. Wiltshire, United States* )

19 643. Injectors for Steam Boilers W. P. Thompson —(*P. P. Hogue and H. G. Wiltshire, United States* )

19,644. Valve Gear, R. McC. Fryer, London.

19 645. Blast-feeding Apparatus for Furnaces, E. Cartwright, Liverpool.

19,646. Inducting Air into Furnaces, J. Mills, Liverpool.

19 647. Manufacture of Artificial Stone, W. Owen, London

19,648. Pneumatic Tires, L Stroud, London.

19,649. Pneumatic Tires, T. S. Paynter, London.

19,650. Windows, T. M. Houghton, Surrey

19,651. Boxes, Bewlay and Co , Ld., A. Needham, and W. Needham, London.

19,652. Steam Generators, H. E Franz, London.

19,653. Curtain Poles, Mouldings, &c., G. Smith, London.

19 654. Telephone Receivers, F. G. Bell and M. Binswanger, London.

19,655. Venetian Blinds, R. Christ London.

19,656. Railway Chair Manufacture, A. E. Muirhead, Glasgow.

19,657. Self-adjusting Ships' Furniture, F. Jörgensen, London.

19 658. Shuttles for Weaving Looms, A. Wood, London.

19 659. Water-closet Seats, C. Darrah and T. R. Kay, Manchester.

19,660. Carriages, F. W. Golby.—(— *Buffara and — Jarrit-Lacombe, France* )

19,661. Driving Gear for Cycles, J. H. Turvey, London.

19 662. Mechanism for Ageing Liquors, T. R. Timby, London.

19,663. Firelighters, N. Clarkson and T. Harrison, Bradford.

19,664. Bicycles and Tricycles, A. J. Battersby, London.

19,665. Changing Box for Cameras, H. G. M. Conybeare, Essex.

19,666. Bicycle Gear, F. W. D. Mitchell, Dublin.

19,667. Newspaper Wrapping Machinery, H. E. Newton.—(*R. Hoe, United States.*)

19,668. Carbons for Electric Lamps, A. F. B. Gomess, London.

19,669. Locks, B. Schlag, London.

19,670. Hair-curling Pins, A. J. Boult.—(*A. C. Jaeger, Austria.*)

19,671. Brakes for Perambulators, J. L. Durward, London.

19,672. Steam Boilers, J. Vanes, London.

19,673. Oil-distributing Apparatus, H. H. Lake.—(*H. See and G. L. Carden, United States.*)

19,674. Machines for Binding Box Corners, A. O. Wood, London.

19,675. Water Towers, E. F. Steck, London.

19,676. Expanding Mandrils, H. Berner, London.

19,677. Pneumatic Tires, R. Pritt, London.

19,678. Injectors, R. G. Brooke, London.

19,679. Steam Boilers, H. Tetlow and T. Harrison, London.

19,680. Appliance for Curling Hair, W. Doman, London.

19,681. Coin-freed Apparatus, W. Miller, London.

19,682. Stopping Railway Trains, O. Imray.—(*La Société Anonyme Pleterij voorhen L. I. Enthoven and Cie., Holland.*)

19,683. Manufacture of Thread Spools, W. H. Good, London.

19,684. Ammonium Chromates, V. I. Feeny.—(*The United States Smokeless Powder Company, United States.*)

19 685. Grain Separating Apparatus, J. Thornton, London.

19,686. Boiler and Superheater, E. Shydecker, London.

19,687. Condenser Carding Machines, E. Kay, London.

19,688. Stamping Cakes and the like, W. F. Curry, London.

19,689. Manufacture of Night-lights, W. G. Smith, London.

19,690. Elevating Apparatus, C. W. Hunt, London.

19,691. Retorts for Heating or Drying, J. Lyle, London.

19,692. Making Solid Petroleum Fuels, J. Lyle, London.

19,693. Making Asphaltic Compounds, J. Lyle, London.

19,694. Stopping and Releasing Liquids, G. Dussau, London.

19,695. Driving Gear of Bicycles, J. T. Gibson, London.

19,696. Regulating the Heating of Boilers, M. M. Brophy, London.

19,697. Apparatus for Heating the Air, M. M. Brophy, London.

19,698. Automatically Closing Doors, E. Wulff, London.

19,699. Appliance for Making Cigarettes, E. Brasier, London.

19,700. Vehicle Wheels, R. Haddan.—(*E. G. Schleicher, United States.*)

19,701. Carrier for a Lady's Purse, J. S. Rubenstein, London.

19,702. Accumulators, G. E. Heyl, London.

19,703. Drawing-off Foul Sewer Gases, C. Jones, London.

19,704. Rims of Wheels for Cycles, T. F. Drew, London.

19,705. Type-writers, J. G. Lorrain.—(*The Remington-Sholes Type-writer Company, United States* )

19,706. Key-boards for Type-writers, J. G. Lorrain. —(*The Remington-Sholes Type-writer Company, United States.*)

19,707. Type-writers, J. G. Lorrain.—(*The Remington-Sholes Type-writer Company, United States.*)

19,708 Type-writers, J. G. Lorrain.—(*The Remington-Sholes Type-writer Company, United States* )

19,709. Under-clothing, E. G. Deedes and G. A. Templar, London.

19,710. Dynamo-electric Machines, I. A. Timmis, Westminster.

19,711. Kilns for Burning Pottery, B. Dawson, London.

19,712 Obtaining Lactyl Compounds, G. W. Johnson.—(*The Chemische Fabrik, late Goldenberg, Geromont, and Co., Germany* )

19,713. Bottle Stoppers, C. de Witt, London.

*17th October*, 1894.

19,714. Raising of Sunken Vessels, A. Leech, London.

19,715. Ferrules for Umbrellas, &c., T. Pounds, London.

19,716. Fixed Surgery Splints, W. H. B. Moorhead, Newry.

19,717. Rail-joints of Railways, F. Willdey, Apperley Bridge.

19,718. Excluding Dust from Bearings, A. E. Schurr, Sidcup.

19,719. Speed-regulating Gear, A. A. Watkins and J. de L. Watson, London.

19,720 Curling-tongs, R Friedel, London.

19,721. Lid or Cover for Saucepans, A. Lowe, Bristol.

19,722 Treating Worsted Fabrics, T. Illingworth, Bradford.

19,723. Flanges for Warp Beams, J. Steel, jun., Bradford.

19,724. Withdrawing Railway Spikes, A. Cochrane Manchester.

19 725. Railway Signal Apparatus, A. H. Cochrane, Manchester.

19,726. Leather Belt and Strapping, F. G. Cockill, Huddersfield.

19,727. Chain Adjustment, B. S. and B S. Roberts and Co., Birmingham.

19 728. Bolt and Nut-lock Appliance, A. D. Kennedy, Glasgow.

19,729. Coin-freed Apparatus, J. W. Johnson, Isle of Man.

19 730. Railway Signals, R. Burn and H. W. Talley London.

19,731. Hose Pipes, W. Wild, Manchester.

19,732. Hanging or Supporting Mirrors, J. Whitehead, Birmingham.

19,733. Electric Clock, W. Hearn and C. R. Gatehouse, London.

19,734. Spanner, H. T. Daniels and J. H. Pick Stamford.

19,735. Inverted Bicycle, B. Doyle, London.

19,736. Adjustable Socket, H. T. Daniels and J. H Pick, Stamford.

19,737. Material for Roofing Purposes, J. Wheeler Ilfracombe.

19,738. Circular Aperture Mount Cutter, S. A. Smith, Salisbury.

19,739. Pleated Paper Bottle Wrapper, L. Wookey London.

19,740. Pulsometers, J. L. Berry and F. Hampson, Manchester.

19,741. Wheels for Cycles and Vehicles, J. Markus, Manchester.

19,742. Electrical Switches, W. P. Theermann, Manchester.

19,743. Valve Guard or Protector, M. T. H. Teagle London.

19,744. Driving Gear, R. O. Cowan and W. Radford, London.

19,745. Roller Mountings for Blinds, P. C. Walker, Dublin.

19,746. Suspender for Ladies' Hose, E. Fottrell Dublin.

19,747. Fittings for Waist-belts, &c , H. Brookes, Birmingham.

19,748. Valves, W. M. Walters, Liverpool.

19,749. Travelling Bags and Fittings, J. B. Brooks, Birmingham.

19,750. Syphon Flushing Cistern, A. Haddow, Edinburgh.

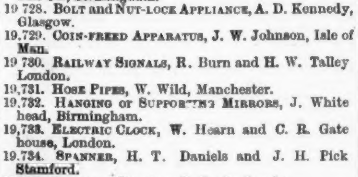
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**524,201.** Reversing Gear for Engines, *D. H. Grant and H. Miller, Raymore, Mo.—Filed March 31st* 1894.

*Claim.*—A reversing gear for engines, comprising a collar keyed on the main driving shaft, and formed with a lug, a sleeve adapted to be shifted axially and circumferentially, and arranged concentric on the said shaft, the said sleeve being formed with a spiral cam groove and a straight slot, of which the spiral cam groove is engaged by the lug on the said collar, and an excentric formed in the bore of its disc, with a lug engaging the said straight slot in the sleeve, substantially as shown and described.

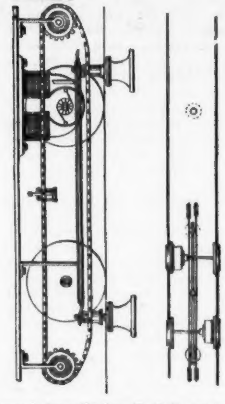
524,201



**524,368.** Electric Railway System, *T. B. Wilcox and H. Wilcox, Newark, N.J.—Filed August 16th,* 1892.

*Claim.*—(1) In an electric railway system, an insulated main conductor, in combination with a series of exposed insulated contact plates arranged along the track and normally disconnected from the said main conductor, a motor car, and electro-magnets carried by the car for connecting the said contact plates to the said main conductor, the said electro-magnets having a continuous movement with relation to the car while the said car is in motion, and the said electro-magnets being just as far apart as the said contact plates are distant from each other, as and for the purpose set forth. (2) In an electric railway system, an insulated main conductor, in combination with a series of exposed insulated contact plates normally disconnected from the said main conductor and arranged along the track, magnetic contact pieces within operative distances from the said plate, a motor car, and electro-magnets carried by the said car and having a continuous movement with relation thereto while the said car is in motion, the said electro-magnets being just as far apart as the said contact plates are distant from each other, as and for the purpose set forth. (3) In an electric railway system, a series of exposed magnetic surface plates arranged along the railway track, in combination with a motor car carrying an endless chain, a portion of which is in proximity to the said series of surface plates, and a series of magnetic devices supported upon the said chain, the said magnetic devices being just as far apart along the length of the said chain as the said surface plates are distant from each other, as and for the purpose set forth. (4) In an electric railway system, a motor car carrying a freely moving endless sprocket chain on which are mounted electro-magnetic devices contained in suitable boxes, a pair of trolley terminals on the said boxes arranged at the same level, and a bar making contact with the said terminals, and simultaneously pressing upon them to steady the boxes and their magnets, as and for the purpose set forth.

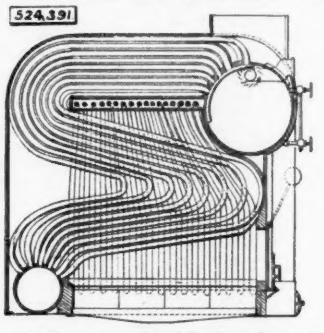
524,368.



**524.391.** Boiler or Steam Generator, *C. D. Mosher, New York, N.Y.—Filed January 7th,* 1893.

*Claim.*—(1) In a boiler or steam generator, the combination of a furnace or fire-box, a water drum located at the rear end of the fire-box, a steam drum located at the front end of the fire-box, said drums extending across the fire-box, a group of curved tubes connecting the upper portion of the water drum with the upper portion of the steam drum, said tubes being bent to form loops disposed in vertical planes extending lengthwise of the fire-box, return pipes extending vertically downward from the steam drum along the front of the fire-box and horizontally along the sides of the fire-box to the water drum, and side tubes springing from the horizontal portion of the return pipes and extending along the sides of the fire-box and constituting a lining therefor, as set forth.

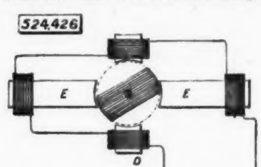
524,391



**524,426.** Electro-magnet Motor. *N. Tesla, New York, N.Y.—Filed October 20th,* 1888.

*Claim.*—(1) The combination in an electro-magnetic motor with a rotary armature of short magnetic cores as D D, and long magnet cores as E E, and energising coils around the same, those on the cores E E being placed at a distance from the inner ends of the said cores, as herein set forth (2) The combination in an electro-magnetic motor with energising coils adapted to be connected with a source of alternating currents, and cores of different magnetic susceptibility, of an armature wound with coils closed upon themselves, as herein set forth. (3) The combination in an electro-magnetic motor with a rotary armature of field cores of different magnetic susceptibility and energising coils thereon connected in series and adapted to be connected with a source of alternating currents, as set forth.

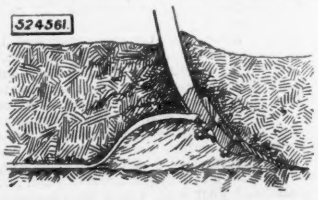
524,426



**524,561.** Cultivator, *J. Porteus, Fresno, Cal.—Filed January 10th,* 1894.

*Claim*—In combination with the shovel and shank of a cultivator, a means for guiding and steadying the cultivator, and preventing its vertical jumping movement, consisting of a bar having its forward end connected with the base of the shank, and its rear extending portion turned to present a broad, flat surface to the ground.

524561.



## EXPRESS PASSENGER LOCOMOTIVES, GREAT WESTERN RAILWAY.

THANKS to the courtesy of Mr. William Dean, the locomotive superintendent of the Great Western Railway, we are able this week to publish drawings of the latest additions to the locomotive power of that line. These engines are remarkable in several respects. They are the most powerful passenger engines at present running in Great Britain It will be seen that Mr. Dean has in the external configuration of the engine and tender adhered to Great Western practice as originated by the late Mr. Daniel Gooch. There is a general resemblance between the Achilles and the Great Britain for example, the bogie taking the place of the four leading wheels of the broad gauge engine. But here, of course, the resemblance ceases, the details being different. Mr. Dean adheres to the raised fire-box, but he adds a dome besides, holding that in this way he can secure maximum dryness of steam, a point of very great importance. Many of the principal dimensions can be obtained from the outline views on page 382, the remainder are set forth in the accompanying tables:—

*Achilles Class.*

| | |
|---|---|
| Cylinders: | |
| Diameter | 19in. |
| Stroke | 24in. |
| Steam ports | 1ft. 2in. × 2in. |
| Exhaust | 1ft. 2in. × 3¼in. |
| Boiler: | |
| Barrel | 11ft. 6in. |
| Diameter outs | 4ft. 2⅝in. and 4ft. 3in. |
| Fire-box: | |
| Outs | 6ft. 4in. × 4ft. |
| Ins | 5ft. 8in. × 3ft. 4in. |
| Height | 6ft. 2in. |
| Tubes: | |
| No. 266, diameter | 1⅝in. |
| Length | 11ft. 9¼in. |
| Heating surface: | |
| Tubes | 1434·27 square feet. |
| Fire-box | 127·06 square feet. |
| Total | 1561·33 square feet. |
| Area of fire-grate | 20·8 square feet. |
| Wheels: | |
| Bogie | 4ft. |
| Driving | 7ft. 8in. |
| Trailing | 4ft. 6in. |
| Water capacity of tender | 3000 gallons. |
| Working pressure | 160 lb. |
| Total weight of engine and tender | 81 tons 10 cwt. |

*Armstrong Class.*

| | |
|---|---|
| Cylinders: | |
| Diameter | 20in. |
| Stroke | 26in. |
| Steam ports | 1ft. 2in. × 2¼in. |
| Exhaust | 1ft. 2in. × 3¾in. |
| Boiler: | |
| Barrel | 11ft. 6in. |
| Diameter outs | 4ft. 2⅝in. and 4ft. 3in. |
| Fire-box: | |
| Outs | 6ft. 4in. × 4ft. |
| Ins | 5ft. 8in. × 3ft. 4in. |
| Height | 6ft. 2in. |
| Tubes: | |
| No. 266, diameter | 1⅝in. |
| Length | 11ft. 9¼in. |
| Heating surface: | |
| Tubes | 1434·27 square feet. |
| Fire-box | 127·06 square feet. |
| Total | 1561·33 square feet. |
| Area of fire-grate | 20·8 square feet. |
| Wheels: | |
| Bogie | 4ft. |
| Driving | 7ft. |
| Trailing | 7ft. |
| Water capacity of tender | 3000 gallons. |
| Working pressure | 160 lb. |
| Total weight of engine and tender | 83 tons 6 cwt. |

The Achilles class are employed in working the principal main line trains between London and Newton Abbot. We annex a memorandum showing the average loading of these trains for one week in the month of June last, before the heavy summer traffic commenced. In the two years ended June last there were twenty of these engines in steam daily, working as under:—Seven at Paddington, working between Paddington and Bristol; eight at Bristol, working between Bristol and Newton Abbot and Paddington and Bristol; five at Newton Abbot, working between Bristol and Newton Abbot. The average consumption per mile of the engines, taken over the whole of the two years, was as under:—Paddington, seven men, 31 lb. per mile; Bristol, eight men, 33 lb. per mile; Newton Abbot, five men, 31·8 lb. per mile. These figures include coal for lighting up.

It will be seen that the boilers for these two classes are identical in all respects, and so are the tenders. It is possible, therefore, to draw a fair comparison between the performance of a single and a coupled engine. Indeed, both types are employed in working the same traffic. But the coupled engines have not been sufficiently long a time at work to permit a trustworthy estimate of their performance to be made at present.

The coupled engines having 20in. cylinders, their tractive effort is approximately 124 lb. per pound of average effective cylinder pressure. Taking this at 100 lb., we have 12,400 lb. tractive effort. The load on the driving and trailing wheels is 31·5 tons, or rather less than six times the tractive effort. At starting, when a pressure 50 per cent. greater may exist in the cylinders, the wheels could be readily made to slip; but the proper use of sand disposes sufficiently of that difficulty. It is well known that 19in. and 19·5in. cylinders have been tried in this country before now, and they have not given satisfaction; but that was mainly, we think, because they were not built with boilers of adequate dimensions. Mr. Dean provides no less than 1560 square feet of surface, a very large fire-box, and nearly 21 square feet of grate surface. If the engine burns 70 lb. of Welsh coal per square foot per hour, the total consumption would be 1470 lb. per hour, and allowing that each pound of coal produces but 9 lb. of steam, we have still 13,230 lb. evaporated per hour, which, at 25 lb. to the horse-power per hour, gives about 530-horse power, which can of course be kept up for any time. The probability is, moreover, that the evaporation would be more nearly 10 lb. than 9 lb., and that the engine would use less than 25 lb. of steam per horse per hour, so that 600 indicated horse-power may perhaps be reckoned upon. Taking the actual consumption, without including lighting up, however, at about 31 lb. per mile, and reducing this to fifty miles an hour as a standard, we have 1550 lb. burned per hour, or 74 lb. per foot of grate, and the actual power developed is probably about 600 indicated horse-power.

Turning now to the single engine, we have a tractive effort of about 9400 lb. for an average pressure of 100 lb., or a little less than one fourth of the load on the drivers. Thus, even with sand, the engines cannot utilise the whole tractive effort of the steam in starting a train; but when running at high speeds the average pressure is less than 100 lb., and consequently the adhesion is sufficient. Taking again fifty miles an hour as a standard speed, which is, as we shall show in a moment, not far from the truth, we find that 7·5 lb. tractive effort represents one horse-power. Taking as before 600 as the total average horse-power, we have 4500 lb. as the tractive effort, which is of course a long way inside the limit at which slipping of the driving wheels would begin.

It is not easy to arrive at the precise weight of the trains. The coaches of the corridor train—that is the 10.15 a.m. down train from Paddington—weigh from 21·5 to 24 tons. The ordinary eight-wheeled coaches, which vary in length from 40ft. to 56ft., weigh from 16·5 tons to 23·5 tons. In taking the average load of the trains as given below, the total number of carriages is divided by the number of days; the result being worked out to the first place of decimals. We shall probably not be very far wrong if we assume that the average weight of a train such as the 5 p.m. is 200 tons, or including the engine and tender, 283 tons, and assuming that 4500 lb. of tractive effort suffices to haul it at fifty miles an hour, we have a resistance of a little less than 16 lb. per ton. As the road is nearly level, it is quite possible that this is very close to the truth, and the fact bears testimony to the ease with which the coaching stock runs. It will be seen, indeed, that if the resistance was much in excess of this figure it would be quite impossible that the engines could do the work on the stated consumption of fuel, unless, indeed, the evaporation efficiency of the boiler and the steam efficiency of the engines are very much in excess of anything we can believe to be possible. It is easy, moreover, to check the results so far by parallel calculations. Taking 600-horse power at 25 lb. of steam per horse per hour, we have 15,000 lb. of water, or 1500 gallons evaporated per hour. The total heating surface is 1561 square feet. Consequently steam is made at the rate of about 9·6 lb. per square foot per hour, which is a high, though not an excessive, rate.

By selecting any other standard speed, something like ideas of precision may be formed concerning the performance of these or indeed of any other locomotives. Thus, if we cut the speed down to twenty-five miles an hour, the average pressure and tractive effort must be doubled in order that the horse-power may remain constant. All such calculations, however, confirm the view that the astonishing statements sometimes put forward concerning the power developed by locomotives will not bear investigation. The ultimate appeal must be to the performance of the boiler. That, of course, does not know whether it is locomotive or stationary; a hint which it is needful to throw out, seeing that many persons appear to think that a square foot of grate or of heating surface in a locomotive must be much more efficient than it would be in a stationary boiler. The only advantage possessed by the locomotive boiler is that as compared with the land boiler of the same type and dimensions, it is much less given to priming, probably because the oscillation of the engine tends to shake the steam out of the water. As to the actual performances of the Great Western engines, we give the Table* A in the next column of trains running at and over fifty miles per hour.

Mr. Dean has produced two splendid types of passenger engines. The only feature in the design to which we think exception will be taken is the raised outer fire-box; but, after all, this can only be a matter of opinion. No doubt it gives more steam room and drier steam, and we are not aware of any countervailing disadvantage except that the boiler possibly costs a little more. The Achilles type ought to be competent to work any conceivable traffic at high speed on a level road, while the Armstrong type will not be less effective on roads with moderate gradients. Both are undoubtedly admirably adapted to the purpose for which they have been constructed, and reflect much credit on Mr. Dean.

## THE MANCHESTER THIRLMERE WATERWORKS

### No. II.

IN our issue of October 19th we gave a map showing the line of aqueduct between Thirlmere and Manchester. We now publish a map showing the contour of the lake at the old level, 330 acres in extent, and also the area covered by water after it has been raised to the full height contemplated, viz., 50ft., when the area will be 800 acres. It is proposed from time to time to increase the supply of water by 10,000,000 gallons per diem. The following table gives the quantity of water impounded, according to the height added to the original level of the lake:—

| | |
|---|---|
| 20ft. | 2,534,000,000 gallons. |
| 30ft. | 4,192,000,000 " |
| 40ft. | 6,066,000,000 " |
| 50ft. | 8,135,000,000 " |

When raised to the full height, 50ft., water will be stored, sufficient to give a supply of 50,000,000 gallons daily for 160 days' continuous drought, after providing for 5,500,000 gallons per diem compensation water. This added to the 25,000,000 gallons procurable from Longden Dale, puts Manchester in possession of a supply of 75,000,000 gallons per diem.

Thirlemere having been selected by the Corporation, a committee of five of their number was appointed to act in the matter. Of this committee the only survivor is Sir J. J. Harwood, who has since been twice Mayor of Manchester, and has been chairman of the Water Committee since 1886. They were given authority to purchase by private contract the land and water rights referred to in Mr. Bateman's report, so as to give the Corporation a good position whenever it was decided to apply for parliamentary powers. This involved the purchase of all rights connected with the lake itself, and of the 11,000 acres of land comprising the drainage area. The Corporation had learnt by costly experience in Longden Dale that unless the whole control was obtained at the commencement of the scheme the expense incurred when additional land was required for works and other purposes was much greater, to say nothing of claims arising from cattle and sheep straying and getting drowned. With the Corporation as owners of the land the tenants are more careful for the safety of their stock, as the loss falls upon the occupier. The wisdom of this policy has been acknowledged, and the example followed by Liverpool and Birmingham, in Wales.

Lake Thirlmere is situated in Cumberland, at the foot of Helvellyn, alongside the road from Keswick to Grasmere, and is about three miles long and a quarter of a mile across at its widest part; its natural depth is about 112ft. at its deepest part. At the southern end the land is flat, and appears to have been covered with water in olden times. At the north-east corner there is a narrow gorge forming the outlet through which St. John's Beck finds

---

"THE ENGINEER"

SWAIN ENG.

its way to the Greta, and ultimately through Derwentwater and by the river Derwent to the sea at Workington.

The surrounding hill sides are very steep and are covered with very little verdure. They consist of silurian rock, and rain falling from the clouds finds its way at once into the lake. The gorge enables an embankment or dam to be readily constructed, and the level of the water to be raised as required. Another advantage gained by taking Thirlmere instead of Ullswater is that the latter is to some extent surrounded by residential property, and lead is worked within the watershed.

The task imposed upon the committee was a difficult and delicate one to undertake. A portion of the property was in the hands of families who had owned it and resided on it for generations. Generally the land was held by "customary or copyhold tenure," which means that the sheep are let to the tenant with the farm and had to be purchased. By June, 1877, the committee felt able to recommend the Corporation to promote a Bill in Parliament to obtain power to carry out the scheme of raising the waters of Lake Thirlmere and conducting them to Manchester. It was stated that the cost of the Longden Dale Works, exclusive of distribution, had been about £90,000 per 1,000,000 gallons per diem, and that the cost of Thirlmere water would be about £100,000 per 1,000,000 gallons per diem for the first 20,000,000 gallons, and about £60,000 per 1,000,000 gallons per diem when 50,000,000 gallons of water per diem was taken from the lake. Up to this time the question of going to Ullswater for an additional supply was still under consideration; but before preparing the parliamentary plans, it was decided, on the advice of Mr. Bateman, to confine the scheme to Thirlmere. The pecuniary value of gravity is shown in his report, wherein he says, "That as Thirlmere lies at a height of 56ft. above Ullswater, if this additional fall was regularly distributed it would save about £200,000 in outlay, and deliver water at the temination of the aqueduct from 15ft. to 20ft. higher than if the conduit was placed at a level to bring water from Ullswater."

This saving he showed would entail a somewhat greater outlay of iron pipes when a further instalment of water was required; but the present saving of £200,000 appeared of sufficient importance to warrant the change. How much greater would the saving of capital have been if Liverpool had joined with Manchester in going to the lakes for a supply? As will be seen on reference to the map published on the 19th inst., the water taken from Rivington for the supply of Liverpool crosses the Thirlmere Aqueduct south of Chorley; and by means of additional pipes laid in the same track, if found desirable, a plentiful supply of water could have been sent to Liverpool.

The Bill was deposited in December, 1877, and a great parliamentary fight began. Not only was there opposition from interested landowners all along the route of nearly ninety-six miles, but also of Corporations of towns, railway and canal companies, and last, but not least, the Thirlmere Defence Association. This Association appealed to the public to preserve the Lake District from the "needless intrusion of works on a large scale." In all thirty-three petitions were presented against the Bill.

The House of Commons devoted two hours to its consideration, on the second reading, it having been urged that two new principles were contained in the Bill, viz., permission for a Corporation to enter into a speculation in water supply, and also the right of one district to resort to another 100 miles away for its water. It was therefore determined that the more formal submission to a Hybrid Committee should be made instead of the usual Select Committee appointed to sit on private Bills. A strong committee of nine members was appointed, on which Dr. Lyon Playfair, now Lord Playfair, was chosen as chairman, and Sir J. Lubbock, who subsequently sat on a similar committee to consider the Liverpool water supply, was an important member. The committee sat during nineteen days, and so strong was the local opposition, that a deputation from Manchester hurried to the neighbourhood, and explained to the inhabitants the advantages they would obtain in the way of employment, in the market for their produce, and the stimulus to trade generally, which the district would derive, if the works were proceeded with. These facts having been brought home to the population, and the local boards having passed resolutions in favour of the Bill, the local opposition was beaten. A careful and exhaustive report was made to the House by the committee approving of the scheme, but stating that towns and rural districts along the line of aqueduct had applied to be provided with water, and that in their opinion such supply should be reserved for them; giving, however, a prior right of 25 gallons a head to the population of Manchester, the cost of supply to be a matter of agreement, but if no agreement could be arrived at, then the cost to be at the rate of 4½ per cent. on the proportion of the capital expended to produce the supply demanded, and a like proportion of an annual sum of £20,000 for maintenance and management—practically a 5 per cent. charge.

Clauses to provide for the supply of local authorities were consequently inserted in the Bill, and were the cause of its failure to pass during the session; the examiner on Standing Orders for the House of Lords having reported that a new object had been brought within the scope of the Bill of which notice had not been given; and in those days, when Lord Redesdale was chairman, it was considered impracticable to obtain the sanction of the House to a departure from their Standing Orders. Since then we have seen both Houses of Parliament very amenable to arguments put forward by Manchester to enable Bills to be introduced which had not complied with Standing Orders.

It was felt that much time and much of the ratepayers' money had been expended in vain, but it was thought that so important a Bill, which was really a commencement of a new era in waterworks legislation, was bound ultimately to succeed, for the Bill had become not merely a Bill to supply Manchester and its immediate neighbourhood, but also to supply water to the large and populous towns in the neighbourhood of the intended works.

In the following session the Bill was reintroduced with the addition of the clauses required by the committee of the House of Commons, and passed with practically no opposition. Thus Manchester became entitled to draw a plentiful supply of water, the quality of which is shown by the following analysis, which also compares the water from Thirlmere with the Manchester supply from Longden Dale, and the Glasgow supply from Loch Katrine. The analysis was made by Sir Henry Roscoe, F.R.S., M.P.:—

| | | | Comparison with | | | |

Manchester water is supplied for use without filtration, and is found to be of excellent quality. The Act of Parliament contains clauses for the preservation of the scenery in the lake district, the operations of which extend to such parts of Cumberland and Westmoreland as are within 23 miles of Thirlmere, and requires that all reasonable care should be taken to preserve the beauty and distinctive features of the district for the public as well as for private owners. All mounds of surplus earth have been suitably planted so that the same may not disfigure the scenery. The surface of the lake may not be lowered below its ordinary level without the previous sanction of the Board of Trade. All valleys have been crossed by syphons, except in crossing the streams and rivers over which the aqueduct is shown on the deposited plans as carried above the surface of the ground. Portions of the aqueduct made in cut and cover have been re-soiled and planted, and no wall or fence has been erected on the land over the aqueduct without the consent of the owner of such land. The time for the construction of the works was limited to three years from the commencement of operations. The capital to be raised for the purpose of the Act was fixed at £3,425,000 to be redeemed by means of a sinking fund sufficient to repay the money raised within a period of 70 years from the date prescribed from the commencement of the sinking fund.

## THE ATLAS WORKS, SHEFFIELD.

On Friday, October 26th, Lord Rosebery and the guests of the Master Cutler visited the Atlas Steel and Ironworks of Messrs. Sir John Brown and Co., and were conducted round, and shown a number of the most striking and important operations, by Mr. J. D. Ellis, the chairman, and with other partners and the staff of the works.

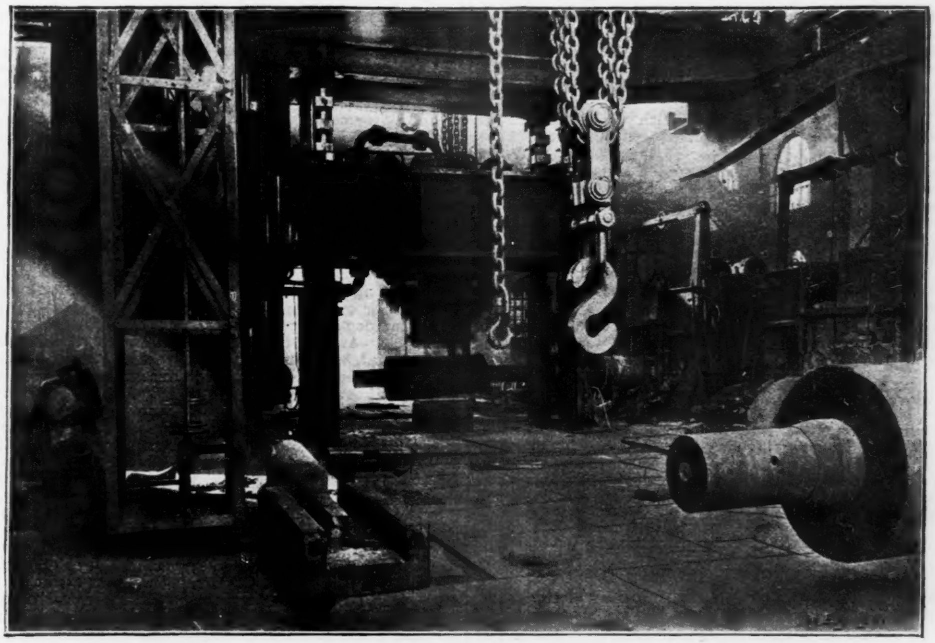
Such a visit naturally calls attention to the features of special interest that exist in such an establishment at the time. Messrs. Brown have obtained exhibition awards for many of the structures and designs seen on this occasion, such as Serve tubes, Purves' ribbed flues, and shafting. The subject of highest interest, however, is the armour now made on the method comprising the Harvey and Tresidder processes. As many of us are aware, some manufacturing difficulties have been caused by the extreme hardness of the face which has produced such remarkable results as a shot breaker; and some doubts have been expressed as to the power of bringing plates with chilled faces to the exact curves required for the different shields. As will be seen below, the former difficulty is met by drilling the holes required in the plate face and filling them with ganister and loose plugs before the hardening treatment, although it is possible with the use of the electric arc drill to make holes, if necessary, when no nickel is present in the armour. The latter difficulty has been overcome by leaving the necessary allowance for warping, and also slightly erring on the side of over rather than underdoing the required curves, as it has been found that a slight correction can be made with the hydraulic press if it takes the shape of compressing the hard steel face, not of stretching it. Probably the application of the jets of water against the upper and under faces of the plate in the horizontal position in the Tresidder chilling process was an operation that had been witnessed by few of the visitors, and the interest may be said to have focussed there, though the forging of a 27-ton plate for H.M.S. Magnificent was interesting to all, and the grand example of a heat burnt and run from the Bessemer converter had its special attractions for any who are not familiar with such operations. We give herewith a short account of the Atlas Works in general, and its armour manufacture in particular.

The Atlas Works are situated on the Midland Railway, were originally purchased by John Brown and Co. in the year 1854, the partners in the original firm being Sir John Brown, Mr. J. D. Ellis, and the late Mr. William Bragge. In 1864 the present limited company was formed, with Sir John Brown as chairman, and on his retirement, Mr. J. D. Ellis was appointed, and from that time has remained chairman of the company. It will be interesting to remember that these works took the first licence from Sir Henry Bessemer for his process, and fought the up-hill fight of the introduction of Bessemer steel rails, tires, and axles now almost universally in use. As has been the case in many subsequent inventions taken up, the first order for steel rails was obtained from abroad, and as an instance of the difficulty to obtain a trial, it was necessary to give a twenty years' guarantee.

At these works mild steel for shipbuilding was produced at the earliest period of its introduction in England, and thousands of tons made by the Bessemer process were supplied to the Admiralty and to private builders. Siemens steel becoming then specified for boiler plates, a Siemens plant was laid down for the same, but in consequence of the extra cost of production, necessitated by the heavy railway rates on raw materials and manufactured articles, the large business in steel rails, ship and boiler plates and bars, in which the works led the van, has been given up, and other industries equally or more important have been developed in their stead.

ARMOUR PLATE PLANING SHOP

The armour-plate manufacture commenced in 1859 with rolled wrought iron plates, which increased in thickness from 4in. to 24in. in course of time. In 1877 the company commenced the manufacture of compound armour on Mr. Ellis' patent system, and from that date this kind of armour has been employed in the construction of the most important battleships and other vessels, both for this country and abroad. Chrome and nickel steel plates are also made, and recently the plant has been laid down for supplying armour treated according to the Harvey and Tresidder patents. The rolling mill now in use was laid down in 1862, and has been in use ever since that date, while in the planing department large and powerful machinery has from time to time been erected, in order to meet the altered requirements of the trade.



THE FORGING PRESS

The blast furnaces were erected in 1873, and are capable of an output of about 1000 tons per week. The ore is principally brought from the company's own mines. The Purves patent flue shop, with its interesting special machinery, was commenced in 1887, and occupies the site of a large iron forge. Over 14,000 of these flues have now been made, and are in use in all parts of the world.

The large hydraulic forging press of 4000 tons power, and the powerful lathes and other finishing machinery, have been working since 1887, and are capable of dealing with the largest shafting and gun forgings. To meet the requirements of the latest type of armour, a new hydraulic press of 10,000 tons power is now being constructed. The large hydraulic press for the flanging of marine boiler plates can deal in one operation with a plate 20ft. by 10ft. It has flanged thus many thousands of boiler end plates, both in iron and steel.

The Serve tube is one of the latest specialities taken up by the company, and a large special shop is almost completed for its manufacture. About seventy ships and four hundred locomotives have been fitted with this special tube to date, and the success attending the same in turning into economy what would otherwise be waste heat has given a great impetus to the demand of late. This tube has also led to a very important improvement in boilers for use both on land and at sea. A much smaller number, or smaller sized boilers give, it is claimed, by the "Ellis and Eaves" suction draught combination the required steam more economically than in the old boilers, without risk to boilers, without smoke, and with much greater comfort to the firemen. Vessels for Australian and Atlantic voyages thus fitted are giving great satisfaction.

In 1873 the company purchased the Aldwarke and Car House Collieries, near Rotherham, which give now an output of about 3550 tons per day of superior gas, steam, and house coal. Recently the sinking of a further large pit, the Rotherham Main Colliery, has been completed, and gradually the output will be increased to about 2000 tons per day. Of this combined large quantity about 700 tons per day are used at the Atlas Works, exclusive of about 150 tons of coke per day, also made at the collieries.

The following are the objects and operations shown in connection with the manufacture of armour:—Historical group of armour plates, illustrating the types of plates in vogue at various periods and the nature of test to which they were submitted for acceptance. Period from 1859 to 1864, wrought iron plates tested with round cast iron projectiles. Period from 1864 to 1877, wrought iron plates tested with Palliser pointed projectiles of chilled cast iron. Period from 1877 to 1879, compound plates tested with Palliser projectiles. Period from 1879 to 1892, compound plates and steel plates tested with forged and hardened chrome steel projectiles.

*Plates of the present day.*—Nickel steel plates introduced about 1890. A 4in. sample was shown that has been tested—without backing—with Palliser shot. Harveyed plates introduced about 1892. These are of steel, with or without nickel. A 6in. nickel steel sample was shown that has been tested with forged and hardened chrome steel projectiles. Two experimental plates were also shown illustrating the wonderful results obtained against the best steel projectiles by submitting the ordinary compound plates to Tresidder's chilling process, which is also used in the last stage of manufacture of the Harveyed plates. These hardened compound plates did not go beyond the experimental stage—an admirable one obtained as award at Chicago.

*Armour-plate rolling mill and hardening apparatus.*—The rolling of a slab weighing thirty-three tons for the production of Harveyed $\frac{9}{14}$in. plate for H.M.S. Magnificent; the chilling of a 9in. Harveyed plate for H.M.S. Majestic. The chilling is practically the final stage in the manufacture of Harveyed plates. The plate is heated in a special regenerative gas furnace, by which a very easily regulated and uniform heat is obtained. The roof of this furnace, weighing twenty tons, is lifted in one piece by a crane, and travelled to one side, while a second crane comes over the furnace, picks out the plate with four dogs, and places it over the lower douche of the chilling apparatus. The upper douche, suspended from a carriage running on overhead rails, is then immediately advanced, and makes an automatic water-tight connection with the pump delivery. A patent indicating apparatus is then adjusted on each of the long edges of the plate, by which the change of form during the whole chilling operation is automatically and instantaneously recorded. This does not take many seconds, and immediately it is completed the then shape of the plate, which may have slightly changed during heating and handling, is known, and the best method of applying the water decided upon. The water is then immediately turned on, and issues from thousands of small orifices with great pressure upon both the upper and lower surfaces of the plate, cooling them almost instantaneously. The application of the water is continued in the case of 9in. plates for from thirty-five to forty minutes, and the plate is then usually from ⅛in. to ¼in. more convex on the face than required by the finished moulds. This convexity is purposely aimed at, because it can easily be remedied by pressure while the plate is cold, whereas an error in the concave direction could not be rectified without going through the whole chilling process again. Absolute accuracy of form from the chilling operation it is practically impossible to secure. After the chilling is finished, the plate is tested with large hardened cast steel punches, struck with a sledge hammer, which must be fractured against the hard surface without making an appreciable indent. All holes in the hard surface required for attachments will have been made previous to the chilling, but the final trimming of the edges to exact shape has to be carried out subsequently. This is accomplished on a planing machine as far as regards the soft portions of the edges, but as the planing tool comes up the edge to within about three-quarters of an inch of the hard surface, the material becomes too hard to be cut with a steel tool. The projecting rib thus left is removed by grinding, either on a large grindstone, or an emery wheel used as a planing tool. Finally, the bolt holes in the back of the plate by which it is attached to the ship are drilled and tapped, and the plates are erected in their proper relative position, and any slight deviation from exactness of fit is further corrected by subsequent grinding.

In the planing shops, one of which we illustrate, large numbers of plates in various stages of completion are to be seen, by far the larger number of them being Harveyed plates. It will be interesting from the taxpayer's point of view to state that the introduction of this class of armour has enabled the naval architect to provide for about £20 the same protection over the same area as previously cost £30, and at the same time to effect a saving of one-third in the weight of armour necessary.

*The forging presses.*—The hydraulic forging press, one of which we illustrate, is a very important tool. It exerts a total power of 4000 tons, and the water pressure, which is supplied by a pair of engines indicating 2000-horse power, is delivered into the press at a pressure of 2½ tons per square inch. The width of the press between columns is upwards of 15ft., and it can squeeze ingots and armour-plates of a total width of 9ft. Messrs. John Brown and Co., having in view the immense weights and sizes of the plates now being ordered by the various Governments, have in course of construction at Messrs. Whitworth's a 10,000 tons forging press which will handle ingots of 70 to 80 tons with much greater facility than the present arrangement of forging presses allows. This will be at work in seven or eight months, and will be the largest forging press in the world.

## THE IRON GATES OF THE DANUBE.

By Bela von Gonda, Chief of the Department of Navigation of the Interior.

In the article on these important works, published in The Engineer on the 8th of June last, reference was made to the interesting remains of the works carried out under Trajan for the improvement of the Danube navigation. Reference was also made to the Stenka cataract, which is the first obstacle on the Báziás-Turnseverin line of the Lower Danube—viz., a rock peak obtruding into the channel, where the fall of the water is not a large one (the gradient being only 0·000357 to 1 metre), and only the required navigable water-depth had to be established. For this purpose a straight waterway will be cut along the left shore at a distance of 300 metres, beginning at the channel of the river, and for a length of 850 metres, 2 metres deep below the lowest water, and of a bottom width of 60 metres, which will be accomplished by the blasting of the rocky bottom; 7400 cubic metres of rock have here to be moved. Fifteen kilometres from this is the double bank called Kozla Dojke, which forms a much more formidable navigation hindrance. It is in the wider channel, above the brooks of the Kozla and Sirinya and the Dojke barricades, the channel below this brook, at the beginning of the narrowing of the channel, so that the current of the river is obliged to leave the left shore and cross to the right to reach the deepest part, which is at the end of the rocky bank Dojke. The removal of the navigation hindrance formed by the rock banks of Kozla and Dojke, where the fall of the water is not so unfavourable, that it could be considered disadvantageous for the navigation—the proportional fall of the low water being 0 00093—only a navigation channel is projected by the blasting of the rocky bottom. This channel will lead from above the Kozla and from the natural current of the river. It takes a curve of large radius along the left shore, cutting through the bank of the Dojke, and will be constructed also with a bottom width of 60 metres, 2 metres deep below lowest water, and it will require the blasting and removal of 76,586 cubic metres of rock.

Eight kilometres from the cataract Kozla Dojke, a whole range of much more considerable navigation hindrances begin. These are the so-called Yzlás-Tachtália-Greben. Here not only the insufficient depth of water, but also the great fall of the water, which is a still greater impediment to the navigation. On the one side, above the rock banks Tzlas and Tachtalia, and below the rock peak of the Greben at low water, the necessary depth for the navigation does not exist in the channel, which widens out instantly; on the other side, the water coming from the channel is choked by the Greben rock peak, opposite the left shore by the rock bank called Vrany, flows into a channel, which is four times as wide, in consequence of which a considerable fall of the water is caused downward from the rock peak Greben. Thus the regulation has on this part a double difficulty. On the one hand, to create the necessary depth of water for the navigation, and on the other hand to stop the fast current impeding the navigation. In consequence of this, an open waterway will be made through the cataract Izlas Tachtalia in the channel along the right shore in a length of 3500 metres, with a bottom width of 60 metres, at a depth of 2 metres under the low water-mark — by the blowing up of 46,800 cubic metres of rocks. Further, the rock peak, which confines the water, causing below it a very large fall—will be cut down to a breadth of 150 metres, 2·8 metres high over the lowest water, and 2 metres above the swollen water surface. Beginning from this peak, at a distance of 500 metres from the left shore, a dyke will be constructed as far as the Servian village Milanovácz—see plan, page 473—whereby the water-surface will be raised in such a manner that on the one part the shallow depths will cease, and the necessary water depth for the navigation will exist; and on the other hand, the large fall of the water below the Greben will be equalised, that is caused to cease, whereby this last navigation hindrance will also be removed.

The whole length of the dyke is 6200 metres; its crown at the Greben above the low water before the regulation 2·80 metres, thence it flows a distance of 2674 metres to where the depth is 2 metres. The dyke will be constructed entirely of stone, with a top breadth of 3 metres, both sides having an inclination of 1 in 15, and the surface of the rubble stone dyke will be pitched as far up as low-water mark, in order that it may resist the action of ice and water.

At a distance of 120 metres, where the dyke fills two deep parts, and where it is exposed nearly perpendicularly to the impact of the current, operating as a cross-dyke or barricade, the dyke will be constructed with a crown of 5 metres with a batten or slope of 1 to 1·75, and towards the right shore, to give it stability to protect itself against the powerful current, with a slope of 1 to 3. In order to distribute the great difference of water surface in the blocked part of the channel, the narrowing dyke will be connected with the right shore by two cross-dykes, which will also be constructed entirely of stone of the same height, but with a crown width of 2 metres and with a slope upward to 1 : 1·5, downwards to 1 : 3. All the materials for the construction of these dykes will be furnished by the Greben rock destined to have a width of 150 metres cut off.

The proposed dyke at Greben-Milnovacz stores the present low-water surface to such an extent that while the necessary depth of navigation, viz., 2 metres below 0, will be obtained at shallow places, the great fall of the water at the Grebens will no longer occur, or will be moderated considerably, and this will be felt as far as the Tachtalia. The maximum damming back or restrictions of the passage of low water is, on the basis of previous calculations, 1·30 metre, whereby the great fall existing especially under the peak at Greben will be equalised at middle water during the season for navigation. By this regulation a very great hindrance of the navigation on the Lower Danube will be removed.

The cataract Tucz, 11 kilometres from Greben, constitutes a similar but smaller hindrance to the navigation, the whole channel being barricaded, like a bottom dyke, by a bank consisting of serpentine rocks, which at low water forms, through its shallow depth, a real cataract, and renders the navigation impossible. At high, and even at mean water level, this bank is submerged, because the stowage, or restriction of flow, of the water formed by the straits of Kazan, beginning at 14 kilometres from the Tucz, reaches to this point, and equalises the surface also above the Tucz. For removing the hindrances existing at the cataract of the Tucz, the regulation must solve a double problem, partly to create the necessary water depth for the navigation, and partly to moderate the great fall of the surface existing at low water. In order to attain this double object, on the one part an open navigation canal is to be formed in the channel itself, near to the left shore, in a length of 1000 metres, with its upper edge bending towards the current of the river, in a depth of 2 metres below 0, and in a bottom width of 60 metres, by the blasting of the rocky bottom. On the other part, a training dyke, at a minimum distance of 300 metres from the left shore, as far as the island, will be constructed from the right shore, beginning at the mouth of the brook Porecska, situated at the Servian village Golubinje, ending at the right shore. This dyke will be constructed entirely of stone for a length of 1600 metres. From a height of 0·5 metre above the flood low water mark, it rises to a height of 1·25 metres, with a crown width of 3 metres, and with slope bending 2 to 3; its top will be paved so as to resist the rushing current. The maximum rise of the water surface formed by the dyke is calculated to be 1·80 metres, and by this the fall over the cataract Tucz, unequally distributed during the low waters—0·00153, 0·0024, 0 005596, 0·00253—will be reduced to 0·00014, whereby—through the deepening of the navigation channel—the navigation will be assured also on this part. These works require the blasting and the removing of 30,000 cubic metres of rocks below the water, and the use of 70,000 cubic metres of stone material for the pressing dyke.

The last and largest navigation hindrance on the Lower Danube is the Iron Gate. There the bank Prigrada, traversing diagonally through the channel otherwise sufficiently wide, in conjunction with the rocky tongues at the foot of the mountain on the left shore, and with the prominent peaks, barricades the current of the river to such an extent that at low water the navigation ceases entirely. Even at middle water the navigation is bound to surmount great difficulties, and the communication of convoys is entirely impossible. The difficulties of navigation at the Iron Gate are so much more considerable than at the other cataracts, because the navigation meets with difficulties at every state of the water level, and is almost always limited, while on the other cataracts the navigation is impeded only at low water. For removing these hindrances at the Iron Gate radical means had to be adopted, whereby the unhindered navigation is rendered possible at every water level. In achieving this object it was decided not to stop or limit the small depth and the great fall of the water and the irregularity of the current—as this would be impossible—but to avoid them. In consequence of this, it was decided to construct a canal separated from the channel by dykes reaching above the highest water level, and this along the right shore, joining closely in an inward bending direction, following the survey proposed by the International Commission in 1873. The plan of the canal was determined in consideration of the existing water level above and below from the Iron Gate, so that these shall be equalised as far as advantageous, and so that the largest convoys shall have sufficient room to pass each other on the way.

For this purpose the Iron Gate Canal was originally projected, with a depth of 2 metres under the lowest water surface, with a bottom width of 80 metres, by removing the rocky bottom. The canal, which—as mentioned above—is dammed with dykes reaching above the highest water surface, begins with a funnel-shaped opening at 400 metres from the upper edge of the bank Prigrada, which in a corresponding length narrows itself gradually to the prescribed width of the canal. This funnel-shaped mouth is necessary, in order that even at the lowest water sufficient water can be obtained to feed the canal, with the required depth for the navigation, at the proportionally greater velocity which will naturally exist in the canal having a passably smooth bed. The canal is directed from the end of this funnel by a curve of a radius of 1770 metres, and a length of 1180 metres, and thence in straight direction it leads to the Servian village Sibb, for a length of 940 metres, so that the whole canal is 2480 metres long. The upper edge of the dyke on the right shore circumvents, by a curve having a radius of 435 metres, the peak of the Kasaina, and is connected at the upper edge of the remains of the Roman bulwarks with the shore. At its lower edge it is broken through by an iron bridge, so that the mountain streams can come down freely. Finally, along the whole length of the dyke, which will serve as a towage path, wooden railings or tramways will be laid.

(*To be continued.*)

## LIGHT RAILWAYS AND TRAMROADS.

The following letter has been addressed to the Associated Chambers of Commerce, the Central and Associated Chambers of Agriculture, the London Chamber of Commerce, the Railway Companies Association, the Institute of Civil Engineers, the London County Council, the Association of Municipal Corporations, and the Association of County Councils:—

Board of Trade (Railway Department),
7, Whitehall-gardens, London, S.W.
29th October, 1894.

Sir,—I am directed by the Board of Trade to communicate with you on the subject of a movement recently set on foot with the object of obtaining further powers and facilities for the construction of light railways and steam or electric tram roads. It has been alleged in some quarters that the requirements which are imposed by the Board of Trade upon new railways in the interest of the safety of the travelling public and of the railway servants, as well as for the public convenience, may stand in the way of those who are desirous of promoting railways through agricultural or sparsely-populated districts.

It has also been urged that light railways may have great utility and importance as a means of assisting those who suffer from the depression in agriculture, by affording them easy and inexpensive means of bringing their produce to the best markets.

The same observation has been made as regards an even more difficult branch of the subject—namely, the possibility of relieving populous urban districts by giving special opportunities to workpeople to travel in and out of towns at a minimum cost, or by making it easier for manufactories to be established in suburban or country districts.

Interest in the movement has no doubt been stimulated by the action of those foreign countries in which light railways have been developed.

The Board of Trade are sensible of the importance of the question in these various aspects, and have taken great interest in the representations which have from time to time been made to the Department, but they have not yet had before them practical proposals which would enable them to decide how far a demand for economy in construction would justify relaxation of any of their usual requirements now enforced in the interest of safe working, and whether a change in the law by which necessary powers might be more easily or cheaply obtained would be likely to be followed by any considerable development of the modes of transport contemplated.

It may, no doubt, be contended that the powers conferred by the Railways Construction Facilities Act, 1864, as amended by the Railways (Powers and Construction) Acts, 1864, Amendment Act, 1870, and the Regulation of Railways Act, 1868 (Part V.), on the one hand, and the Tramways Act, 1870, on the other, are sufficient to satisfy the requirements of ordinary trading companies desirous of constructing and working light railways or tramroads. The Board of Trade are, however, so much impressed by the desirability of obtaining all the information which can be afforded by persons interested in the movement, that they think it well to take prompt steps for the purpose of eliciting and focussing such views and information. And they conceive that both local authorities and traders, as well as the existing railway companies, will welcome an opportunity of joining in a discussion inaugurated with this object.

I am, therefore, directed by the Board of Trade to inquire whether the —— would be disposed to depute —— members of their body to attend such a conference at the Board of Trade on an early day, with the object of discussing:—

(1) How far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely populated and agricultural districts.

(2) Whether additional legal facilities for obtaining powers to construct tramroads and light railways are necessary or desirable.

I am, Sir, your obedient servant,
Courtenay Doyle.

To the Secretary the ——.

## RAILWAY MATTERS.

A disastrous collision occurred on Wednesday between two passenger trains at the station of Redfern, a suburb of Sydney. A Reuter telegram says six persons were killed and thirty injured.

The branch railway being made by the London and North-Western Railway Company to connect their system with the Ship Canal is progressing rapidly. The cutting on the north side of the main line east of Eccles station is finished, and has the bottom ballast laid on, and several bridges have been built. A very considerable area of land is fenced off close to the junction, which will be no doubt used for marshalling and shunting purposes.

Substantial financial support has been promised to the proposed new railway from Bristol to London, *viâ* Bath and Andover. A committee has been formed to further the scheme, which provides for a central station at Bristol, with access to the docks. At a meeting of the Bath citizens on Wednesday, it was stated that it was proposed to run over the Midland line from Bristol to Bath, where several streets would be crossed by viaducts, thence under and over the Great Western Railway, and, passing through a tunnel under the hills on the south-east side of Bath, emerge into Wiltshire at Limpley Stoke, and continue past Trowbridge on to Waterloo.

The regularly recurring hot season brings in its train a list of casualties among the Tramway Company's horses in Calcutta, as well as other places where this system of locomotion is in vogue, which *Indian Engineering* says is heart-rending. But apart from this, there is much to be advanced from the public point of view against relying upon horses for regularity and certainty of transit to their places of business. In such centres as Calcutta, Bombay, Madras, mechanical power should be insisted upon for the working of tramways, since it is unaffected by weather, and journeys may be timed with fair accuracy, which it is impossible when animal power is relied upon.

The bases of a preliminary convention between the French and Spanish Governments have been agreed upon for the construction of two international railways crossing the frontier near the ports of Salou and Somport. The first is to start from Saint Girons in Arriège, ascend the Satat Valley and penetrate into Spain by Esterri de Anen, to terminate at Lerida, while the second will leave Oloron in the Basses-Pyrénées and form a junction at Zuera with the Barcelona and Saragossa line. An international station is to be built on each of the two slopes, and the two tunnels to be driven for each line will be from 7 to 8 kiloms.—mean four and a-half miles—long. The works of the Oloron line, begun in Spain, must be completed in five years, and the duration of all the works is limited to ten years from the ratification of the convention.

Compressed gas for locomotive headlights has been used for some years in South America, and this light is being applied on twenty-five suburban engines now being built by the Brooks Locomotive Works for the Central Railway of Brazil. The Pintsch system is used, under the Safety Car Heating and Lighting Company, of New York city. The new engines have gas lamps in two 20in. headlights, four signal lights, and a gauge light in the cab. The gas tank is below the floor of the cab, and the lights at either end can be turned down according to which way the engine is running. In tests recently made on an engine in the Hoboken yards of the Delaware, Lackawanna, and Western R.R., an American contemporary says, it was found that while the light was much more powerful than the oil lamp commonly used, it did not interfere with reading the signals, as the electric headlight is said to do.

The Portsmouth Town Council had before them on Tuesday two schemes of railway extension to Portsmouth, which are being promoted by certain landowners of Hampshire, and were referred last week to a committee for consideration. One proposed new line would run from Portsmouth to Basingstoke, a distance of 25 miles, *viâ* Waterlooville, Meonstoke, and Alton, into a branch from a point near Meonstoke, to join the Didcot and Newbury Railway at Winchester. By this route an independent service of trains, it is said, would be secured, whereby Oxford, Worcester, Bedford, and the Midland counties would be brought within easy access to Portsmouth without change of carriages. The other line would connect Portsmouth with Basingstoke. The committee expressed a decided preference for the latter scheme, and the council unanimously agreed with the recommendation. The preliminary expenses, which are estimated at about £7000, have been practically guaranteed.

The special staff of clerks sent by the Railway Clearing House Association to assist the Board of Trade in their inquiries into the railway and canal rates, left Richmond-terrace on Wednesday, having completed their work, which has extended over five and a-half years. Lord Balfour of Burleigh and Sir Courtenay Boyle had several thousands of Railway Acts before them, which they cancelled and embodied in about forty Acts relating to England, Ireland, and Scotland; and a very large number of Canal Acts, some of them dating back to the time of Charles II., are now incorporated under fifteen Acts. The analysis of the Railway Acts has already been published by the Board of Trade, and the analysis of the Canal Acts will shortly be issued. Mr. Charles Smith and his staff return to the Railway Clearing House, the Board of Trade having conveyed their thanks to the railway authorities for the admirable services rendered during the inquiries into the Railway and Canal Rates.

In the course of 1893 the Russian Government took over the Moscow-Kursk, 341 miles; Orenberg, 372 miles; Donetsk, 444 miles; and Baltic, 378 miles lines of railway. During the present year of 1894 the Government have acquired the Nicholas Railway, with the Putiloff branch, 420 miles; the St. Petersburg-Warsaw line, 804 miles; the Moscow-Nijni, 284 miles; the Mitau line, 85 miles; and the Riga-Dunaburg line, 136 miles. Negotiations are now pending for the purchase by the Crown of the South-Western system of Russian railways. On the other hand, the Government ceded to the South-Eastern Company the Oriel-Griazi line, 193 miles; and the Livna Railway, 38 miles. On the 1st of January, 1894, the total length of the railway lines belonging to the Government, exclusive of the Trans-Caspian and Ussuri lines, amounted to 9761 miles, while the length of private railways, including the Moscow-Kazan line, extended over 8933 miles. The whole railway system was not much extended during the past year.

Electricity is to be used for lighting the cable cars on the Brooklyn Bridge, in place of the present oil lamps. At the last meeting of the Bridge Trustees, a report on this subject was handed in by Superintendent C. C. Martin, to whom the subject had been submitted. He reported that the Safety Car Heating and Lighting Company had submitted the following bid:—To equip sixty cars complete, with four 4-burner lamps each, or a total of 160-candle power for each car, for 14,708 dols. Including repairs, attendance, and interest on equipment, said Mr. Martin, the cost of using Pintsch gas would be 7½ cents per hour per car; if the bridge operated its own gas plant, it would cost 4·4 cents per hour per car. The General Electric Company proposed to equip sixty cars with ten 16-candle power lamps each, together with engines, dynamos, and complete plant, for 14,200 dols., and to guarantee that the operating expenses should not exceed 4905 dols. per annum. Taking the interest on the first cost of the plant at 5 per cent., or 710 dols.; depreciation and repairs at 6 per cent., or 862 dols., and adding these to the operating expenses, gives 6478 dols. for the total annual cost. This, says Mr. Martin, is equivalent to a cost of 5·3 cents per hour per car. Thus a heavy outlay is to be made for electric lighting, which will cost much more than the gas now so successfully used.

## NOTES AND MEMORANDA.

In London 2413 births and 1481 deaths were registered last week, or 310 and 101 respectively below the average numbers in the corresponding weeks of the last ten years. This decrease in the rate of increase is now very rarely departed from.

The deaths registered last week in 33 great towns of England and Wales corresponded to an annual rate of 18·5 per 1000 of their aggregate population. In spite of its struggle with its water supply, Leicester was lowest but one on the list, namely, 12·4; Croydon being lowest with 10·2.

The total number of supplies furnished by the London water companies during August was 809,202, representing an increase of 902 supplies on the previous month, and the total supply divided by the number of supplies shows a daily average of 241 galls. for each such supply.

The number of miles of streets containing water-pipes constantly charged in each London water company's district within the metropolis is as follows:—Chelsea, 85¼; East London, 185; Grand Junction, 135; Kent, 177⅛; Lambeth, 202; New River, 346; Southwark and Vauxhall, 160; West Middlesex, 133¼; total, 1423⅝ miles. Throughout this extent of streets hydrants for fire purposes can be fixed.

A recently tested form of roller bearing has for its rollers small closely wound spiral springs of rectangular section, the thickness of the wire being from about 15 to 30 per cent. of the diameter of the spring. This roller is intended to give just sufficient spring to make the difference between absolute incompressibility and that slight elastic compressibility which will prevent deformation of either roller or journal.

The average daily supply of water to London, delivered from the Thames during the month, was 108,586,290 galls.; from the Lee, 48,942,635 galls.; from springs and wells, 37,609,439 galls.; from ponds at Hampstead and Highgate, 3802 galls. The last is used for non-domestic purposes only. The daily total was therefore 194,142,166 galls. for a population estimated at 5,457,971, representing a daily consumption per head of 35·75 galls. for all purposes.

In a paper in the *Comptes Rendus*, "On the Degree of Incandescence of Lamps," by M. A. Crova, the conclusions given are:—(1) That the quantity of light emitted by a gas burner per litre of gas used increases with the quantity of the combustible burnt per hour, whereas the degree of incandescence slightly diminishes, up to a maximum yield which should not be exceeded; (2) that for lamps with incandescent substances, the maximum yield corresponds to the minimum amount of the combustible which must be burnt in order to obtain the maximum degree of incandescence.

The strength of a brick arch, having a span of 13ft. 1½in. and a rise of 1ft. 11⅝in., was recently ascertained at Beaue, France, with a view to determine the suitability of such a construction for a service reservoir now being built there. The *Australian Builder and Engineer* says:—"The bricks measured 11·8in. by 5·1in. by 1·2in., and were laid flat with a joint of cement mortar 4in. thick between them, and an ·8in. layer of mortar outside. A section 2ft. wide was built on rock abutments, and loaded with 820 lb. per square foot, which load was carried without any signs of failure for eighteen hours."

M. Raoul Pictet, who, with M. Cailletet, was the first to liquefy oxygen gas, has, according to the *Globe*, recently found that phosphorescence ceases at temperatures from 130 to 140 degrees below zero of the Centigrade thermometer. Phosphorescent substances, such as the sulphides of strontium, barium, calcium, lithium, when cooled to this temperature lose the property, but regain it when their temperature rises higher. M. Pictet hopes to introduce an apparatus capable of giving a temperature of 100 deg. below zero Centigrade, that is to say, a temperature as much below zero as that of boiling water is above it.

A French process of casting hard glass consists in first melting the material in a peculiar tank furnace, tapped into moulds, a special substance being used in place of sand, the mould and the glass inside of it being also heated and cooled together. The mixture to be used in the place of sand is selected so as to have as nearly as possible the same conductivity and capacity for heat as glass, in such a case the glass and mould forming, as it were, one homogeneous body. The glass thus treated cools, it is said, without cracking, even if the cooling process be comparatively quick, which is quite necessary when hard glass is to be produced.

A paper on observations of the pendulum in the Alps of Dauphiny was recently read before the Paris Academy of Sciences. The values obtained for the constant of gravitation are given below in column $g_0$, for comparison the values calculated for each place at latitude $\phi$ from the formula $g_1 = 9{\cdot}78124\,(1 + 0\,0005243 \sin^2\phi)$ are appended. The values of $g_0$ are corrected to sea level by means of the densities of subjacent formations taken from the most recent work:—Paris, $g_0$, 9·81013; $g_1$, 9·81030; Valence, 9·80640, 9 80682; Grenoble, 9 80603 9·80705; La Bérarde, 9·80530, 9·80682; Marseilles, 9·80539, 9·80536. *Nature* says the variation of the observed from the calculated value at La Bérarde becomes less when a correction is made for the influence of the mass of the surrounding mountains, $g_0$ is then 9·80575.

M. Raoul Pictet recently described some new experimental researches on the congelation of sulphuric acid of different degrees of concentration. Four extensive series of experiments carried out on large volumes of the acid, in different ways and with all the precautions indicated by the study of the laws of crystallisation at low temperatures, yield concurrent curves which include the cases between pure $H_2O$ and pure $H_2SO_4$. This curve crosses the line of zero temperature five times—including origin with pure $H_2O$. On descending parts of the curve the liquid contains a larger proportion of acid than the solid, on ascending parts the inverse is the case; at the summits of the curve the titre of the liquid is the same, *Nature* says, as that of the solid. The maxima and minima do not, in general, correspond to definite hydrates.

Writing on the use of liquid carbonic acid gas for chilling test pieces, especially stone, iron, and steel, at low temperatures, M. Ph. v. Haller, in the *Industrie Zeitung* of Riga, says that a cheap and simple form of apparatus in which the test specimens could be cooled would consist of a wooden box with double walls, top and bottom, the spaces between being filled with some non-conducting substance. The liquid gas could be led into such a box from the iron or steel flasks in which it is furnished, and would be deposited in great part in the form of frost at a temperature of about 78 deg. C. The test specimens could be readily put into and taken from such a box, and would quickly get a low temperature. One of the Russian railroad companies is on the point of having such an apparatus constructed for testing rails and wheel tires at low temperatures. The possibility of accomplishing the desired object with such an outfit, viz., the rapid freezing of specimens, was demonstrated by putting a number of iron test pieces into a bag of several thicknesses of coarse cloth and then introducing the liquid gas. This at once became solid and filled all the spaces between the specimens which thus lay packed in snow. Each specimen was provided with a depression into which mercury could be poured, and on doing this, after a short exposure in the freezing bag, it was found that the mercury immediately solidified, showing, in the absence of a suitable thermometer, that the temperature of the specimens was certainly below 39 deg. C., if not lower. At the St. Petersburg Laboratory of Experimental Medicine a cold room of quite large proportions has been fitted up in which also liquid carbonic acid is the cooling agent.

## MISCELLANEA.

It is stated that a third petroleum fountain has been discovered at Groonaia, in the Caucasus, yielding about 10,000 tons a day.

The success of the electric motors for moving the guns of H.M.S. Barfleur has been so complete, that it is proposed to employ them on H.M.S. Renown.

The Directors of the Eastern Counties Coal Boring Association have accepted the tender of the Vivian Boring and Exploration Company, of Whitehaven, for carrying out the search for coal, and operations are to be commenced within the next few weeks. The *Standard* says the first bore will be made upon the estate of Mr. W. J. Graham, at Sutton, on the banks of the river Stour.

Circumstances especially favourable to the electrician exist in Seville. Owing to the high price of gas it is estimated that the electric light, supplied by meter, will not cost the consumer more than he pays at present for gas. Accordingly an electric light company has commenced laying cables, and it is expected that it will be possible to give the electric light at the end of May, 1895.

A report on the southern approach to the Tower Bridge, agreed to by the Parliamentary and Improvements Committees, has just been submitted to the County Council. It recommended that the line of route proposed in the Bill of last session should be agreed to, and that the Bill should be re-introduced next session, but after discussion it was agreed to adjourn the consideration of the subject.

The Secretary of State for Foreign Affairs has received from her Majesty's Consul at Corunna a dispatch announcing that the Spanish Minister for Public Works invites tenders for the construction of a dock at San Estevan de Pravia, in Asturias. The cost is estimated at £70,000. The plans, &c., may be seen at the Ministry in Madrid, and at the Department of Public Works in Oviedo. Tenders will be received up to November 30th.

After being in existence for about a quarter of a century, the Beaver Line, between Liverpool and Canada, is to be stopped. The Line, which is owned by the Canada Shipping Company, has for many years performed weekly services of cargo and passenger steamers between the Mersey and Montreal and Quebec. The Line commenced with sailing ships, and some twenty years since there was inaugurated a steam service. The fleet comprises five steamers.

The following is another instance of the now too well-known undermanning of the engine-rooms of her Majesty's ships:—Application was recently made to the Admiralty for an extra engineer for the Dromedary, on the ground that she is a 1300-horse power vessel with nine auxiliary engines, and that while a ship in the Navy of this horse-power would carry an engineer and three artificers, there is only one engineer on the Dromedary. The application was refused.

Under Wilsons Loan Charity, loan are granted at £2 per cent. interest to young tradesmen under the age of 40 years carrying on business in the City of London, or within five miles of the City, who have been set up in business one year and not more than three years and succeeded in business. Three unquestionable sureties are required for £100, and four for £200 or £300. Personal application should be made to the Clerk of the Trust, Chamber of London, Guildhall.

The Art Gallery Committee of the City of Manchester has arranged to hold an exhibition of contemporary arts and crafts, in the rooms of the City Art Gallery, in April next. It is sought to bring together a display of fine examples of industrial art, with a view to educate the public taste, and to stimulate the desire for all that is excellent in design and workmanship. Especially is it desired to identify the actual designers and skilled workers in respect of the exhibits offered.

The Italian Naval Committee has examined and reported favourably upon a new type of ironclad of the first class. Signor Brin is responsible for the plans of this new war vessel, which is said to be entirely different from any existing type either in Italy or abroad. Its chief characteristics are very high speed, with the submersion of very nearly the whole of the body of the vessel, a method of construction which has already been suggested and advocated in our pages.

It is announced that the municipal authorities of Bordeaux have determined to organise an international exposition of arts and industries, to be formally inaugurated the 1st March next year. It is proposed that the exposition shall comprise ten sections, of which the sixth is to be devoted to mineralogy, chemistry, and mechanics, and the ninth to only one subject, electricity. Up to the present England, Italy, Spain, Switzerland, Belgium, and Portugal have been invited to co-operate in the undertaking.

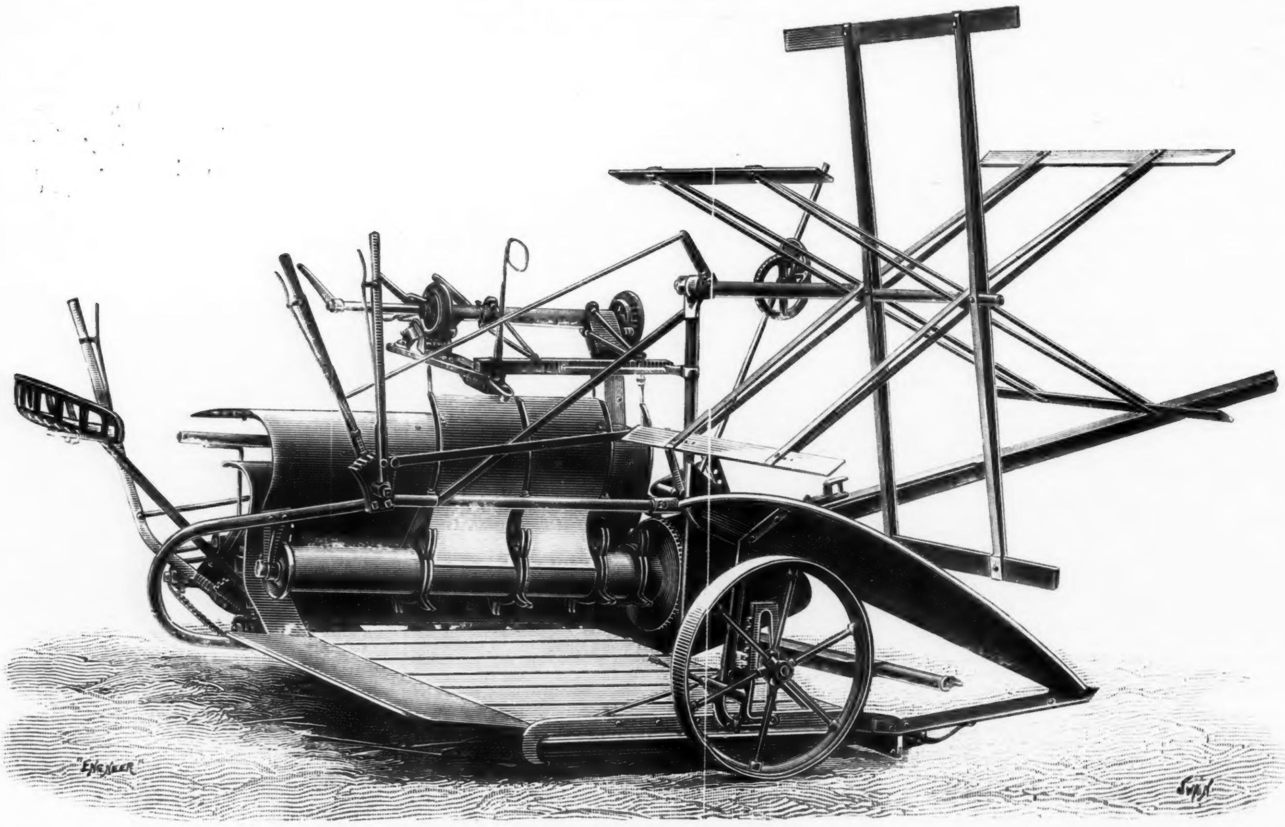
It is stated that the Government of Western Australia has just decided to construct a lighthouse on Cape Leewin, an important promontory on the south-west extremity of Australia and the first point of Australian land sighted by vessels bound to the Antipodes. The erection of the light was suggested some years ago by Mr. W. T. Douglas, M. Inst. C.E., consulting engineer to the Trinity Board. The Agent-General, Sir Malcolm Fraser, has issued an order for a quick-flashing revolving light.

The Board of Agriculture have received through the Foreign-office a despatch from her Majesty's Consul-General at Monte Video intimating that an agricultural exhibition will be held in that city by the Rural Association of Uruguay, with the co-operation of the Government of the Republic, from March 1st to March 31st, 1895. The exhibition will be divided into three sections, viz.:—(1) Live stock and poultry, and their products; (2) agricultural machinery and implements of all kinds; (3) agricultural products. Of these three sections, the second alone will be international, the remaining two being reserved exclusively for native exhibitors. Applications for space must be made by December 31st next, addressed to the managing committee. Forms for making such application may be obtained from the officers of the Rural Association of Uruguay, Monte Video.

The report on the working of the Indian mints in 1893-94 states that the imports of gold into India during the year were much larger than in 1892-93, having amounted to 472,635 oz., valued at Rs. 3,14.65,303, against 272,442 oz., valued at Rs. 1,78,17,891, in 1892-93. The imports in the latter year were, however, unusually small, and the exports greatly in excess of the imports. The value of the metal tendered for coinage in the Calcutta mint was Rs. 29,720; but no gold was coined during the year. In the Bombay Mint no gold was tendered for coinage or coined during the year. The net imports of silver during the year exceeded the imports in 1892-93 by 8,805,461 oz., and this although the imports of the latter year were exceptionally large, having been exceeded only three times during the last half century, and notwithstanding the fact that the mints were closed to the coinage of silver within a few days of the conclusion of the first quarter of the official year. Owing to this circumstance the coinage of silver in the two mints was only about 38 per cent. of that of the previous year, being smaller by Rs. 7,87,90,263. That there was even so much silver coined is accounted for by the fact that a considerable quantity of the metal imported by the exchange banks, and landed in India subsequent to the closure of the mints, was taken by the Government on special terms and used for coinage.

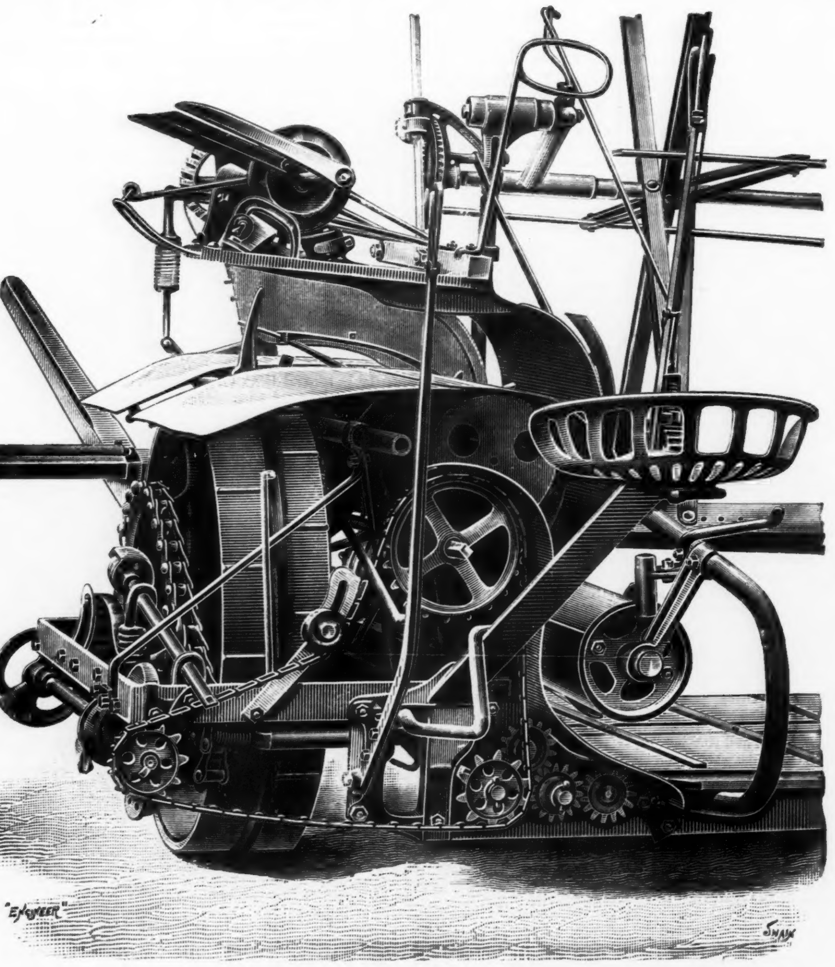
# SAMUELSON'S NEW LOW-DOWN HARVESTER

MESSRS. SAMUELSON AND CO., BANBURY, ENGINEERS



## SAMUELSON'S NEW LOW-DOWN HARVESTER.

THE new low-down harvester illustrated by the accompanying engravings has been made this year, and very fully tested during the past summer and autumn on crops of various kinds. It is the result of long-continued endeavours to make a machine in which the binding is effected at a lower level than is usual with the older forms of sheaf binders, and also to perform the work without the pair of vertical elevator webs generally used. The horizontal travelling web is used as usual to carry the cut crop towards the elevator, which in the new machine consists of a rotating cylinder with four sets of lifting prongs, as seen in Fig. 1 of our engravings. This roller carries a crown bevel wheel as shown, which is driven by a pinion on the front end of the spindle, which is itself driven by the chain and wheel shown in the lower part of the left-hand corner of the platform seen in Fig. 2. The four prongs on the elevator roller lift the crop high enough into the gathering chamber formed by the plate iron guards shown in Fig. 1 to place it within reach of the rotating picker arms, by which it is lifted and pressed up to the binding arm on the binding table situated immediately over the main travelling wheel.



LOW-DOWN HARVESTER—REAR VIEW—Fig. 2

Above this binding table is placed the knotting mechanism. After sufficient grain has been carried up by the packers on to the binding table to form a sheaf, the knotting mechanism is thrown into gear, and the needle rises from below the table, compresses the bundle, and the knot is formed, and the sheaf discharged by means of the ordinary discharge arms to the side of the travelling wheel, shown in Fig. 2. An efficient separation is obtained by the stoppage of the rotary packers at the throat or upper part of the gathering chamber, which prevents the loose grain from following the bundle which is being bound and discharged. As soon as the tied bundle is thrown off the machine, the needle again descends under the binding table, the packers again come into action, and bring forward the cut grain from another bundle, the actions of the parts being as usual automatic.

The driver is placed at the back of the machine, as shown by both engravings, so that he is in full view of the standing crop, and can see the whole of the operations, namely, the gathering and cutting of the crop, the formation of the bundle, the tying of the knot and discharge of the sheaf; at the same time the levers for raising and lowering the reel for tipping or tilting the finger beam, and for moving the binder head and knotting mechanism backwards and forwards so as to place the string in the proper position upon the bundle or sheaf, are all within his easy reach. The sizing of the sheaf is effected by the usual means. The whole machine is so compact that it passes without difficulty through a 9ft. gateway without taking the horses out or using any transport. This arrangement secures a reduction of over 2ft. in width, as compared with some of the ordinary type of elevator machine, with which it is necessary to use a separate transport arrangement, and to unhitch the horses, so as to allow the machine to be taken sideways through the gateways and along narrow roads. The position of the knotting mechanism above the binding table, as previously mentioned, is shown by both engravings, and is of Messrs. Samuelson's improved form of the Appleby knotter. It is within sight of the driver, and easy access for adjustment. The remainder of the packing gear and other parts of the mechanism are also very readily accessible.

The grain is raised less than a total height of 3ft., being a saving of 12in. to 15in., as compared with some elevator machines. The advantage attending the use of only one canvas, and dispensing with the two elevating canvasses and the necessary framing for carrying them, are considerable.

We recently saw one of these machines at work, hauled by a pair of horses, and cutting a late crop of wheat. It was a light crop, but was in parts very heavy with strong weed and thistle growth, and was badly laid, some of which could not be lifted by machine. This crop the machine dealt with in what, under the circumstances, was a very satisfactory manner, the separation being good, except now and then when the heavy weeds and cross-laid stuff, which no machine could deal with passed through. Already several of the machines have been sent abroad where harvest is about to commence, and there is no doubt the machine will create a large demand. The weight of the machine is from 11½ cwt. to 12 cwt. in working order.

## TEDDINGTON SEWAGE DISPOSAL WORKS.[*]

By HENRY YORK, F.S.I.

TEDDINGTON is situate on the Middlesex bank of the river Thames, and is distant about twelve miles from London. It has an area of 1214 acres, of which about 17 acres consist of water. The present population is estimated to be over 11,000, and is rapidly increasing. In 1871 the population was 4050, in 1881 the population was 6595, in 1891 the population was 10,020, the rateable value is £56,000. The parish is generally very level, the surface being about 25ft. above O.D., except towards the north-west, where the ground rises to about 65ft. above O.D. This rising ground is, however, chiefly farm land, the greater part of the populated portion of the parish having a variation of level of only 1ft. in 1½ miles. The soil consists principally of alluvial gravel which overlies the London clay. This

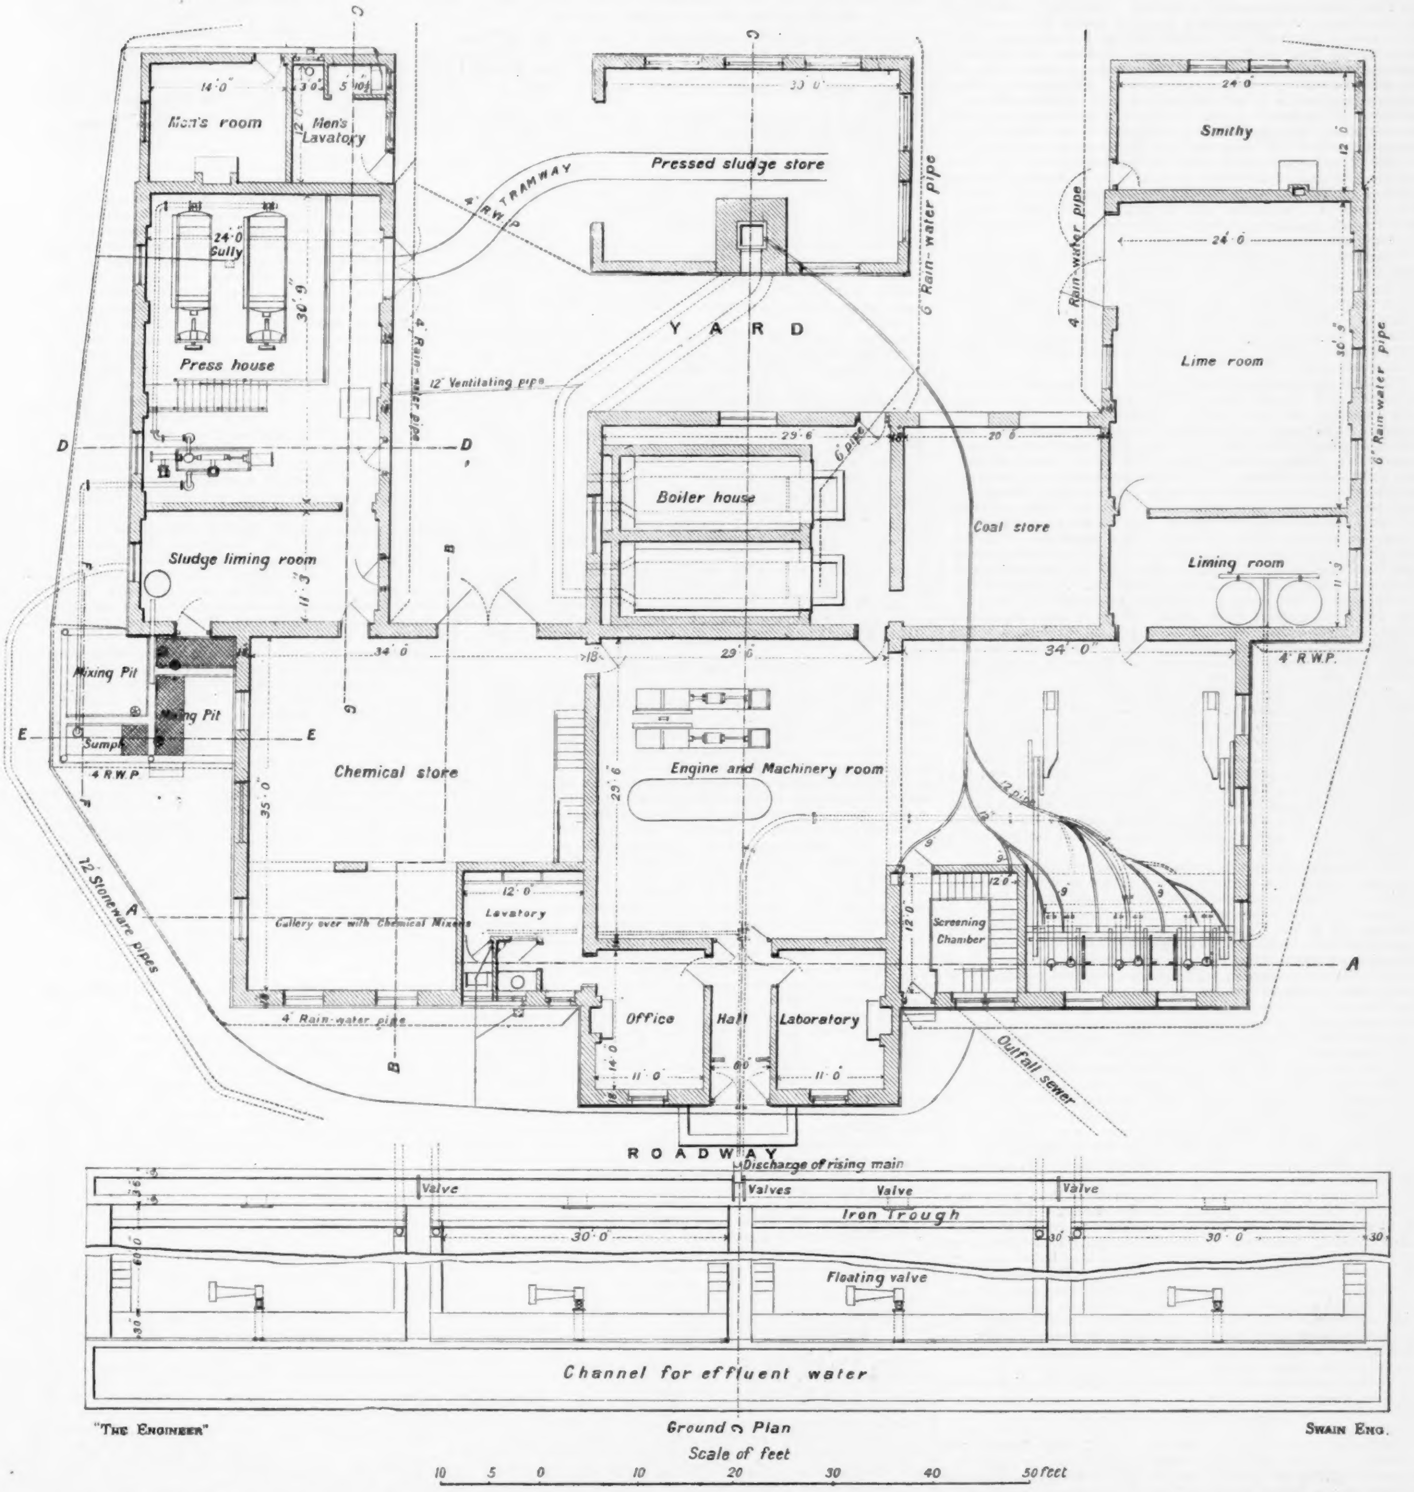
[*] Paper read before the Incorporated Association of Municipal and County Engineers, Saturday, June 23rd, 1894.

# TEDDINGTON SEWERAGE WORKS—GENERAL PLAN



"THE ENGINEER" SWAIN ENG.

Ground Plan

clay is generally found at a depth of from 18ft. to 20ft. below the surface, but in a few places it crops up nearly to the surface. The subsoil water at the present time is chiefly at a depth of from 6ft. to 8ft. below the surface, although in some places where the clay forms basins I have observed the subsoil water to be at a depth of only 18in. below the surface. In a few instances, on the other hand, water is not found nearer to the surface than 10ft. or 12ft. One result of the subsoil water being found in such shallow depths has been, that wells have been sunk in large numbers, and these wells being frequently in close proximity to percolating cesspools, the risk of the contamination of the water was very great.

In the very early days of the parish many of the houses were drained direct into the Thames by means of the ditches or small watercourses which intersect the parish. These naturally soon became a nuisance, and were built over in places, forming culverts. These culverts were the earliest form of sewerage in the parish, and from them arose the present system of storm water sewers. In 1865 the Thames Conservancy obtained an Act prohibiting sewage from being discharged into the Thames below Staines, and accordingly Teddington, with other places, was required to prevent all sewage from being discharged through the storm water drains. The Local Board, which was established in 1867, then set to work, and to a very large extent freed the storm water drains from sewage. They also, from time to time, extended the storm water drainage, until now the district has a system of storm water drainage almost equal in extent to the new system of soil sewers. One of the most beneficial results which followed upon the laying of the storm water drains was the lowering of the subsoil water. The drains in certain instances were laid with the avowed object of lowering the subsoil water, the pipes being jointed only half round.

So far it may be said the district was drained entirely by cesspools, and notwithstanding the liability of the wells to become contaminated the inhabitants were very fond of them, drank the water freely, and generally lived to a good age. In 1877, however, all the districts of the Thames from Molesey and Hampton to Barnes and Mortlake were combined to form what was known as the Lower Thames Valley Main Sewerage Board, the object of which was to obtain a scheme of outfall and disposal for the sewerage of the several districts. This Board had the reputation of being the most energetic and extravagant Board ever known. Innumerable schemes for the interception and disposal of the sewage were considered, and one—designed by the late Colonel Haywood—was approved by them, and a Local Government inquiry extending over forty-three days was held; this scheme was not sanctioned. Subsequently another scheme by Messrs. Mansergh and Melliss was put forward, and an inquiry held upon it. This scheme was approved by the Local Government Board but was not carried out, owing to some of the contributory districts forming the joint Board successfully petitioning Parliament to dissolve the Board. Thus ended the first efforts towards the sewerage of this district. The joint Board was afterwards dissolved.

The necessity for sewering the district, however, was increasing; and in 1887 I was instructed to prepare a scheme for the sewering of the district, Mr. Melliss being appointed by the Board consulting engineer in the matter. The first business of course was to obtain a site for the work of pumping and disposing of the sewage, and eventually the present site of the works was obtained privately through the then chairman of the Board—Mr. H. Page. The scheme was then put into shape, an inquiry held by Major General C. Phipps Carey, and the sanction of the Local Government Board obtained for raising a loan for the work. The sewerage scheme, as executed, does not vary in any appreciable degree from the original design. It consists of about fourteen miles of sewers ranging from 9in. to 21in. in diameter. Branch sewers have also been carried up from the main sewers to all existing houses. All are stoneware except where the railway is crossed, and there an iron pipe is used. They are laid without exception at self-cleansing gradients, and it is calculated that sewage will reach the outfall from the most distant part in one hour twenty-two minutes. Another contract is about to be entered into by the Board for an extension of the scheme through all the private roads, which will add another four and a-quarter miles to the length, making a total of over eighteen miles of sewers. Owing to the level character of so large a portion of the district, it became necessary to have an intermediate pumping station near the railway station. The sewers accordingly gravitate from the upper part of the district to that spot where the sewer—a 15in. pipe—is 21ft. below the surface, or 9ft. above Ordnance Datum. This sewer takes the sewage from all that part of the district lying west of the Kingston line of railway. The intermediate lift is effected by means of Shone's ejectors, of which there are three of 300 gallons capacity each, two being capable of doing the maximum required work, and the other being kept in reserve. The sewage is discharged by the ejectors into an 18in. gravitating sewer which conducts it to the outfall works. The remainder of the district has sewers which gravitate to the outfall works.

The main outfall sewer is 21in. in diameter and about 26ft. below the surface, or 1ft. below Ordnance Datum. At the upper end of each main sewer is an automatic flushing tank. These tanks contain from 750 to 1100 gallons of water, according to the length and size of the sewer into which they discharge. Many of the intermediate manholes are provided with flushing discs. The ventilation of the sewers is at present by means of openings in the manhole covers in the surface of the roads; but the question of sewer ventilation is now receiving the very careful attention of the Board, as I find that even with efficient flushing and carefulness in other matters smells occasionally arise from the gratings.

Although the present population is only about 11,000, the capacity of the sewers is sufficient to receive the sewage from a population of 30,000 persons, calculated at 45 gallons per head per day, half this quantity being allowed to pass away in six hours. The outfall sewer, which is at a gradient of 1 in 700, has a discharging capacity of 353 cubic feet per minute, with a velocity of 147ft. per minute when the pipe is running half full. The sewage is discharged into the purification works at the depth of 26ft. below the surface of the ground, and is there pumped to a total height of about 36ft. into the precipitation tanks. Previously to entering the pump well the sewage passes through a close screen in order that it may be freed from rags and substances likely to affect the pumps, and milk of lime is added to it, the mixing of the milk of lime with the sewage being performed by the operation of pumping. Chemical mixers are situate on the gallery in the room which on the present occasion is devoted to the purpose of the luncheon, and these are of sufficient height to inject the alumino-ferric into the rising main of the pumps before it leaves the building; by this means the sewage is deodorised entirely within the sewers and the pumps, thus providing against all risk of nuisance at the works from the smell of sewage.

The arrangement of the works is such that the Board may adopt any other chemical treatment if so desired. The sewage containing the chemicals is discharged direct from the pumps into a channel at the head of the tanks, from which channel it is conducted into either of the four precipitation tanks, which are of sufficient capacity to contain collectively 225,000 gallons, or nearly one-half the estimated daily flow from a population of 13,000 persons. The tanks are constructed so that they may be used either on the continuous or intermittent principle. The effluent water from the tanks after the sewage has been precipitated is conducted by the channels provided for the purpose to the filtration area which is $6\frac{3}{4}$ acres in extent, and which, with the exception of a small osier bed, is under drained at a depth of about 6ft. These under drains intercept the effluent water passing through the land and convey it by means of a stoneware pipe drain 15in. in diameter to the river Thames, discharging into the tidal portion of the river at a short distance below Teddington Weir.

To return to the purification works, the effluent water having been drawn from the tanks, the remaining sludge is swept up to the drain which conducts it to the sludge pit which is situated under the pressing house. The sludge has a small quantity of lime added to it, the mixing of the lime with the sludge being performed by means of compressed air, and then pressed, rendering it easily portable, the liquor from it being conveyed back to the sewer for re-treatment.

The air-compressing machinery by Messrs. Hughes and Lancaster or working the Shone's ejectors, which are about one mile away, s in duplicate, and is situated in the same room as the pumping engines. The pumps are arranged on the triple principle, and the engines for driving them are in duplicate, either engine being powerful enough and so arranged as to drive any two or three of the pumps if necessary. The sludge presses are in duplicate, we have also two 30-horse power boilers, one to work all the engines and machinery, the other as a standby. The machinery and tanks are designed so as to be readily capable of enlargement—if necessary—to deal with the sewage of a population of 30,000. The pumps are of the kind known as vertical plunger pumps, fitted with Okes' patent valves, which are specially adapted for sewage, and were supplied by Messrs. Owens and Co. An inspection of the diagram of the pumps, kindly lent to me by the patentee, Mr. Okes, will explain their action. They are each capable of lifting 450 gallons per minute, working at 38 revolutions. The engines driving the pumps are of the ordinary horizontally single cylinder kind, and were made by Messrs. Marshall, Sons, and Co. The sludge presses are those of Messrs. Johnson and Co., the sludge being pumped direct into the presses without the use of compressed air. The boilers are Messrs. Galloways' patent, 18ft. long and 6ft. diameter. The pump well and the sludge pits are ventilated by pipes into the chimney shaft. The lime and chemical mixers are those of Messrs. Johnson and Co., and the mixing is performed by means of compressed air; this I have found to be a very convenient arrangement, and the lime mixers perform their work very efficiently. The water required for chemical mixing and boilers is obtained from a well in front of the buildings and pumped into tanks in the roof by means of a donkey pump.

The buildings are lighted by electricity, which is generated by a dynamo worked by an arrangement of pulleys from the pumping engine; for ordinary purpose of work the speed of the engine is sufficient to obtain a very good light. Teddington was the first place in the United Kingdom whose sewage works were lighted by electricity. Seeing that we obtain water on the premises and generate our own artificial light, we are entirely independent of all water and gas companies. The character of the building is of good class, it being felt that it was due to the locality that a building of some appearance should be erected, and I moreover felt that where sewage has to be dealt with, against which there is considerable sentimental feeling, the better and more pleasant the surroundings are the more that sentiment is overcome. The entire cost of the sewers and disposal works has been £50,655.

The works have now been in operation and have successfully treated the sewage for the last twelve months. Until the end of last month pumping was carried on only during twelve hours of each day, but it was found that there were several objections to allowing the sewage to accumulate in the sewers during the night. An experiment of continuous pumping has, therefore, been tried, which so far has given most satisfactory results. I find that there is less smell from the manholes, and the sewage can be more easily treated at the works. Flushing is facilitated, and the flow being more regular the machinery can be used to better advantage. Continuous pumping is of course more expensive, but the advantages are so many that I shall urge my Board not to return to intermittent pumping. The quantity now pumped is equal to 379,000 gallons per twenty-four hours, the coal consumption being 22 cwt. per twenty-four hours. The chemicals used are lime, about five grains per gallon; alum, $3\frac{1}{2}$ ditto. The population at present draining into the sewers is nearly 5200; but this number is rapidly increasing, and fresh connections are being made with the sewers daily.

In a succeeding impression we shall publish additional drawings of these works.

ELECTRIC LIGHTING IN LONDON: A LARGE ORDER FOR ENGINES.—One of the largest orders yet given out for engines for electric lighting in London, or perhaps anywhere, has just been placed by the British Thomson-Houston Company in the hands of Messrs. Willans and Robinson, for the Bankside Station of the City of London Electric Lighting Company, as part of one of the largest orders for electric lighting plant ever determined at one time. There are eight engines in all, of 700 indicated horse-power each, coupled direct to Thomson-Houston alternators, and we believe they form part of a complete order which the British Thomson-Houston Company have received for engines, dynamos, boilers, pipes, exciters, &c. The Thomson-Houston Company have already put down at this station four engines of 300 indicated horse-power each, coupled direct to their alternators, and it is no doubt the successful working of these which has led to the present order.

THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—The Society visited on Saturday last the works of Messrs. Maudslay, Sons, and Field, of Lambeth, over which they were taken by Mr. G. M. Lemmi, on behalf of the firm. The party were first shown the historical portion of the works, which is the birthplace of modern machine tools, the self-acting lathe having been invented and constructed by Maudslay. Lathes constructed as long ago as 1800 are still at work, as also are three table engines constructed as long back as 1824. The members were then shown the engines in course of construction for H.M.S. Renown, together with a number of engines for torpedo boat catcher vessels. A pneumatic dynamite gun was then inspected. Various propellers in phosphor bronze, cast, and wrought steel, were shown. The visitors were then taken to the "Belleville" boiler, and were shown the simplicity of its arrangement, the ease and facility with which it is worked, the readiness with which steam can be raised, and the many other good qualities of this boiler. This type of boiler is not an experimental one, as it is now becoming largely used by both mercantile and naval vessels. The two warships Terrible and Powerful are to have boilers of this type; the French have adopted them, the Spaniards have adopted them, and they are in use in some of the largest mail steamships. Another type of water-tube boiler, the "White," is also constructed at these works, it having proved very efficient; it is used principally for the smaller class of vessels, such as torpedo boats. The party then visited the smithy and foundry, the latter being famed for the excellence of its productions. The model room, an important feature of this establishment, was not passed over.

## LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

### THE LATE MR. EDWIN CLARK, M.I.C.E.

SIR,—It will probably be interesting to the readers of THE ENGINEER to hear that Mr. Edwin Clark, in 1844 and 1845, was an usher in a proprietary school owned by the late Rev. Edward Wickham, called Eagle House, and situate at Brook Green, Hammersmith.

That school was famous for preparing boys for public schools. At one period the headmasters of Eton (Dr. Warre), Winchester (Dr. Ridding, Bishop of Southwell), Harrow (Dr. Butler, Master of Trinity, Cambridge), and Wellington (Mr. Wickham, Dean of Lincoln) were quondam pupils at the school alluded to.

The position held by Mr. Clark was that of arithmetical and writing master. Many a rap over the knuckles he dealt me with a ruler for not following his instruction in respect of writing, which at the time I did not appreciate, and I am afraid that judicious punishment did not have the effect of making me an efficient caligraphist. He was much liked by the boys, was a first-class botanist, entomologist, and musician, and took much pains to impart his knowledge to those who had a liking for the subjects he knew so well.

Few men after the age of thirty could adopt a skilful profession such as that of a civil engineer, and become so eminent as he did. He must have felt sadly misplaced as a subordinate teacher in a private school; and instructing small boys in the rudiments of mathematics must have been a most uncongenial employment to so able a man. It was a lucky incident in his life which brought George Stephenson and himself together, and the undertakings carried through successfully by the former under the supervision of the latter are records of the great perseverance and skill displayed by those distinguished engineers. Smiles, in his life of George Stephenson, in alluding to the construction of the "Britannia" and "Conway" Bridges, describes Clark as the former's "able assistant," and states that the hydraulic power used in the erection of those bridges was after a method originally suggested by Clark.

Doubtless Stephenson in erecting the Victoria Bridge at Montreal was greatly assisted by the knowledge and experience he had gained in constructing the tubular bridges above alluded to, and which were completed under Clark's supervision.

Cambridge, October 29th. BROOK GREEN.

### LOCOMOTIVES AND TRAINS.

SIR,—I have read your leading article on "Locomotives and Trains," in your issue of the 26th October, with great interest. I was a passenger by the train that met with the accident, and being unhurt, I was able to make some observations on the state of the train, which very much surprised me, and have continued to furnish abundant matter for reflection. Like the other correspondents to whom you allude in your article, I possess no special acquaintance with the conduct of railway traffic. But I think the observations which I was able to make, and which in their general lines were published in a letter to the *Times* of the 5th October, are worth stating with a little more precision in a paper such as yours, where they will come under the notice of professional railway engineers, who may possibly be able to make some use of them.

I was travelling in one of the ordinary East Coast sleeping cars, which at the time of the collision was third carriage from the rear. I heard the danger signal blown by the goods driver, and noticed that the brakes were put down instantly. After probably not more than five or six seconds' violent jolting the train stopped. On looking out of the window nothing seemed to be amiss with the train, and I expected every moment that it would start on again. I only learned the truth when the guard came along with his head covered with blood, and reported that the whole of the front part of the train was demolished. I then got out to see what had happened, and to render any assistance that I could. Fortunately and miraculously all the passengers were—like myself—unhurt, and the wounded drivers and stokers were being attended to by several medical gentlemen. Bonfires were soon made out of the *débris* of the wagons, and it was possible to see the damage which had been done.

The condition of the train was roughly as follows:—The two engines were wrecked, the pilot one being thrown over on to the down line, and partially down the embankment. The guard's van next the engine and two third-class carriages behind it were demolished, the two third-class carriages being squeezed out to the left by the Pullman car, which came immediately behind. The body of the Pullman had been wrenched separate from the bogie truck frame which carried it, and slid along it, driving the third-class carriages out sideways, and penetrating into what remained of the guard's van. Behind the Pullman was an ordinary sleeping car which also had slipped forwards on its bearings, but was otherwise undamaged. The carriage behind this was very little hurt, and the remainder—some seven or eight carriages—were standing on the line, just as if they had been stopped in the ordinary way, and neither they nor their occupants had suffered any damage at all. Shortly, the engines and the great part of the train up to the Pullman car were destroyed. One or two carriages in the middle of the train suffered slightly, and the rear half of the train, consisting of at least seven carriages, was unhurt. The train was running at a high speed when the danger signal was given by the goods engine driver, and the brakes were put down instantly. Had there been no continuous brake, there would have been no sensible reduction of speed before the collision, and the carriages would have been piled one on top of another, and the loss of life would have been appalling. As it was, none of the passengers were hurt, but the guard in the front van got an ugly knock on the head, and the four men on the engines were seriously hurt. Could these men and their engines not have been saved? Looking at the train as it stood after the collision, it is evident that if, at the moment of putting down the brakes, the forward part of the train had been made to disappear, the rear part of the train would have stopped under the influence of its own brakes before reaching the mineral train which was on the line, and no collision would have taken place. If, on the other hand, at the moment of putting down the brakes the rear half of the train had been removed, the forward portion of the train would have run with greater violence into the mineral train, because it would not have had the drag of the after portion, which was efficiently braked. Hence the conclusion is forced, that if the forward half of the train had been as efficiently braked as the after portion no collision would have taken place.

An ideal distribution of brake power would be such that, on shutting off steam and applying the brakes, the train as a whole should come to a standstill in the shortest possible distance, and each individual vehicle making up the train should have its speed reduced at the same rate as every other one, so that there should be neither pull nor push between neighbouring vehicles. The brake distribution in the ordinary carriages of the Scotch express seems to approach this standard sufficiently for practical purposes. It is when we consider the engines that the great defect is apparent. The tender is always fitted with powerful brakes on all of its six wheels; but so have all the ordinary coaches, which do not weigh half as much as the loaded tender. Formerly the engine was entirely wanting in brakes, but gradually they have come to be fitted with them, but the friction surface supplied is quite insignificant when their great mass is considered. We may take the engine of such an express to weigh at least four times one of the ordinary coaches, yet the brake-blocks applied to its wheels are seldom of greater surface than those of the ordinary coaches. The leading wheels are never supplied with brakes at all.

As the velocity of every portion of the train is the same, the brake friction or retarding power ought to be proportional to the weight of each vehicle. If the pressure per unit of area of rubbing surface is the same in each vehicle, then the area of rubbing surface ought to be in proportion to the weight of the vehicle. This proportionality does not exist in any of our railways, when the ordinary carriages are compared with the locomotives. To the ordinary lay observer there would seem to be no insuperable difficulty in fitting an engine which has four 7ft. driving wheels and four bogie wheels in front, with four times the brake surface which can be applied to an ordinary six-wheeled carriage. It would be very interesting to know, from the professional side, how it comes that this great difference between the power which the driver has of stopping the train of carriages and that of stopping his engine has been allowed to continue. Had there been no such difference, the East Coast Railway would to-day be the richer by three or four carriages, two express engines, and the services of four experienced men. J. Y. BUCHANAN, F.R.S., F.C.S.

London, October 29th.

SIR,—I see that in your leader on this subject you have taken up the defence of the authorities, but you have not directly dealt with the point which I endeavoured to emphasise. It can be simply enough stated, and is this: If there are two engines, one of an old design, cheap to build, light in weight, and economical of fuel and repairs, and the other of a higher first cost, more expensive to work, and 50 per cent. heavier on the road; and if of these two engines the latter cannot work trains any heavier or faster than the former, then I think that you will agree with me that the older engine is the better of the two, and that, in default of some altogether fresh design being forthcoming, the most sensible thing to do would be to revert to the old practice.

I have no means of knowing whether or no your other correspondents are in "positions of authority," but am glad to see that THE ENGINEER is inclined to hold the official position theory at its true value. One constantly sees sententious paragraphs to the effect that no one can possibly tell as well as the engineer in charge what particular type of locomotive is most suited to the work to be performed on any particular railway, the inference being that whatever is is best, and that outside criticism is little short of impious. And yet, what is it that almost invariably happens when a locomotive superintendent dies or retires? A new engineer is appointed, and, having the same traffic to deal with under the same conditions, forthwith proceeds to build engines quite different to any hitherto in use on the line, and as often as not obtains better results than his predecessor. Surely this disposes of the argument that because those in authority approve of a particular type of rolling stock, that type must necessarily be the most suitable.

You refer to high speed and heavy loads as an excuse for the use of two engines; but the tendency of late has been to divide and lighten trains, and every one knows that under the pressure of bad times speed has been falling off all over England for some years; so that the work demanded of the locomotives of to-day is certainly no harder than that of the recent past, and it must be admitted that for some reason or other the newest locomotives on certain railways seem unable to accomplish it as successfully as those which they have been built to replace.

You make two charitable suggestions to account for the employment of a pilot engine on the night of the Northallerton accident, one "that there should be no delay or hesitation at climbing banks," the answer to which is that there were no banks to climb; and the other "that the pilot was only a light engine working home." But unfortunately for this view, the pilot was a Darlington engine, and was just starting away from home, and it has been specifically stated that it was taken on because the train engine was short of steam. W. B. THOMPSON.

Devonshire Club, St. James's, S.W.,
October 30th.

SIR,—I was very much interested in your leading article of last Saturday on railway speeds in connection with the correspondence arising out of the recent accident to the Scotch express. As you say, the subject is not a bit understood, and I am sure that having it so clearly explained as you have done will do good. The difficulty in making up time at high speed is very striking. Thus, to take the case you mention, 10 miles to be run at 60 miles an hour, average line, omitting the hill you introduce, suppose the driver is a couple of minutes to the bad when he comes to this length of 10 miles, which he generally runs in ten minutes. If he runs it, say, at 65 miles an hour, he is then only making up one minute in every 13 miles, and if he runs it at 70 miles an hour, he makes up one minute in every seven miles. He is probably so timed as to make it necessary to do the 10 miles about as fast as he can every day, so that trying to pull up even a couple of minutes in this length is out of the question. Again, if he relaxes the speed 10 miles, say, to 50, he is losing time at the rate of one minute in every five miles. Thus, from a speed of 60 an increase of 10 miles only gains one minute in every seven miles, but a decrease of 10 miles loses one minute in every five miles. You are quite right in saying that engines are worked up to their full capacity. I had twelve months' firing—six on goods and slow trains and six months on expresses—after I served my time, besides a good deal of riding on engines since, and therefore know something about it. There is another point which is often overlooked by people who make timetables and others who ought to know better, and that is the time lost in stopping at and getting away from big stations. You cannot run into stations like Rugby, or Crewe, or York, and stop as you would at a roadside station, nor can you get away from them in the same style.

If you look at the down Irish mail, 8.20 p.m. from Euston, in "Bradshaw," you will see that the time stands thus:—London to Rugby, $82\frac{1}{2}$ miles in 104 min., 47·6 miles per hour; Rugby to Stafford, 51 miles in 65 min., 47 miles per hour; Stafford to Crewe, 25 miles in 33 min., 45·4 miles per hour; Crewe to Chester, 21 miles in 28 min., 45 miles per hour; Chester to Holyhead, $84\frac{3}{4}$ miles in 109 min., 47 miles per hour. The timetable speed from Stafford to Crewe, and Crewe to Chester, is about two miles an hour slower than the rest of the run. But the actual speed required between those places is as fast—if not faster—than that on the rest of the journey; the reason being that the distances between are shorter, and they are large stations where time is lost approaching and leaving. As bearing on the present craving for high speed, it is a question whether the game is worth the candle; a very slight increase either in speed or load, will eat up any saving in coal that the locomotive superintendent can make. A. H.

London, October 30th.

SIR,—Instead of taking up your space with "dimensions"—already familiar to your readers—I will forward to "Scrutator" full particulars, if he will give me his full address. Having no theoretical knowledge of the subject, I cannot presume to discuss the virtues of any particular engines; but was simply asking for information as to whether the enormous increase in working expenses is fully accounted for by shorter hours and increased pay of employés; or whether it does not largely date from the employment of such heavy locomotives, and the running of such an unnecessary number of nearly empty express trains. A short speech made by Mr. Macdonald at the discussion on "Compound Locomotives," at the Institute a few years ago, seems to fit the—shareholders'—case exactly. F. BOWLES.

London, October 30th.

SIR,—That two engines were on the unfortunate train in the late accident at Northallerton, proves nothing as to the inefficiency of modern locomotives. Any man who understands railway working will tell you that a second engine is often attached, as you suggest in your excellent leader, in order that a man may get home. It is certainly better that he should assist a train than go light, or be "booked off" away from home. When standing on the footplate I have often been asked, by one of these amateur railway men, why two engines were attached to a certain train of moderate weight; but to jump to the conclusion that one of them—and as suggested, the modern one—is therefore inefficient, is too absurd to need further comment; and the imputations made by your correspondents against modern locomotives are, I consider, unjust and unfounded. H. A. C.

October 31st

### MORE DOUBTS AND SOME CONJECTURES.

Sir,—Colonel Basevi's letter expressing doubt of things accepted and "wanting to know, you know," has whetted my ever-existing thirst for information, and stirred the old doubts into expression. Perhaps some one of your correspondents will kindly dispel the doubts by satisfactorily proving that they only arise from my ignorance.

What is gravitation? What is "the ether?"

Gravitation? Oh, gravitation is, of course, the attraction that one body has for another. Newton, you know, discovered it. Very well, but why that attraction? Why should one body attract another? Let it be admitted that gravitation is a stopgap phrase halfway explaining; but is it not time—here we are at the end of the nineteenth century—that the essence, the remainder, of the explanation was forthcoming.

We know that heat, light, and electricity are practically interchangeable or convertible one to the other. Never mind the exceptions just now. Do they count much in accepted theories? Example, "Every particle of matter in the universe attracts every other particle." How about the pith ball experiment, and like poles of magnets?

Now we all know that electricity is potential energy. We receive light and heat from the sun. But how does the heat reach us? In producing a vacuum in any vessel is or is not the ether extracted with the air? Do the light and heat rays travel as light or as something else, and are converted to light on reaching our atmosphere, or does the ether convey them, as we must assume for the present there are no molecules to assist their passage? It is difficult for me to conceive of heat passing where neither molecule nor atom exists. We won't tackle the wave theory now, thank you.

Work is done by the sun upon the earth in holding us in our orbit. Work is done by the sun in holding all the planets in their orbits, and the same work is done by the planets upon the sun each tending to pull it in its own direction; the attraction is mutual and the work equal:—unorthodox.

Now if the sun were a gigantic arc lamp or an electrically incandescent mass, the centre of a great electric "field"—the best word, I think—as well as a gigantic mass retaining by its attraction many smaller bodies in their orbits in one plane, would the proportion of heat each planet obtains from the sun be in proportion to its mass, and therefore its attraction, or in proportion to its surface?

We know the earth is a magnet, but is it an electro-magnet or a permanent magnet? Let us assume it is a permanent one; then how did it become magnetised? We cannot conceive of its being magnetised in either of the ways we should magnetise a steel or iron rod to form a permanent or temporary magnet, except that of passing a current through it; also, except the magnetisation by induction in the manner of a steel poker standing vertically, but then the poles of the earth and of the sun, the only possible magnet of sufficient power to serve this purpose, are not "end on." And the earth being a magnet, and granting that light is convertible to electricity, then most light is received from the sun in the tropical regions. What becomes of this absorbed light? It must go somewhere, it cannot be completely dead, or the conservation of energy becomes a dead phrase. It cannot exist as light, it is not all reflected, it must therefore be changed. Let us assume that it is converted to electricity in some unexplained way, and we have a current passing in at the centre of the magnet and out at the poles, causing the rotation of the magnet, the earth, and producing the continuous auroræ, the light of the return current to the poles of the sun; and this energy is continually moving in this circuit back from the poles of the planets to the poles of the sun, and from the sun to the planets as light and heat.

There is a theory that a portion of the interior of the earth is molten, but always cooling—the sequence of the nebulous condition. True, the earth grows hotter the deeper we delve, and volcanoes and earthquakes occur; but are they proofs of a molten core? Then, why the dormant intervals when volcanoes rest and earthquakes sleep? Now, those currents continually passing through the earth to the poles, find here and there a greater resistance, and consequently the interior of the earth is maintained at a fairly-high temperature; but in a few places the resistance is exceedingly high, either continuous or set up at intervals by the perturbations of other planets, and you have local incandescence produced and the phenomena of volcanoes, earthquakes, and geysers.

Why should it be assumed that there are no gases filling the planetary space? It seems to me highly probable that air, in a highly rarefied condition, fills the plane of the ecliptic, if not all space.

It is very unorthodox, it is very unfashionable, to assume—except upon the accepted bases of assumption.

Let us now make a big assumption. The Milky-way is a series of planetary systems, each with a central sun, all arranged in one mighty ring. The suns are in the core or central line of that ring, and for ever passing round that ring from sun to sun is a current of electricity, assisting to maintain the incandescence of the suns. Hence the attraction of the sun for the planets, and the retention of the planets in their orbits; and also their rotation round the sun in what is practically one plane. In the moons, the currents making magnets of them are induced.

I know there are many profound and unexplainable gaps in this assumption, particularly the passage of the electricity from sun to sun round that ring, but then we have so long been in possession of the roof and the chimneys of the Castle Gravitation, without the castle and its foundations, and I want to suggest that we ought to set about possessing ourselves of the castle. I was struck with the similarity of the positions when a well-known scientist exhibited a planet—I mean an egg, spinning on a plate by the aid of a current beneath it—some time ago. All the planets revolve round the sun in one direction. It is really a question for the mathematicians whether the vast sum total of the work done by the planets upon the sun as the work is equal to the work done by the sun upon the planets, is not sufficient to generate heat upon the sun to largely assist in maintaining, if not alone producing a condition of incandescence, in its crust, seeing that it is only a small portion of the sum of the work done by the sun that is done upon the mass of the earth, and yet it is sufficient to maintain parts of the earth in a state of incandescence. It is true that the mass of the sun is greater than the total mass of the planets.

One feels inclined to kick at the idea that man should put a limit on the working of the planetary system, and calculate a time for its ceasing to work, like an old clock—for this is what cooling means—because he finds that a continuous or perpetual motion is impossible here. And it is chiefly because of the difficulty of conceiving a continuously balanced action without loss, a continuous working the whereof we see not the cause, the one part of the system reacting upon the other without waste of energy or heat, that we wish to bring the infinite down to the level of our finite views, and limit it by our own conceptions and experiences. We do not know, we do not understand; therefore we say that the sun and the earth must be cooling, because this accords best with our own puny experience, and because this fits with the very ingenious nebular theory.

Then, again, as to that continuous battery and bombardment of molecules. Is it not more consistent with well ascertained facts, a less strain upon our faith, and more in accord generally with what we know of the phenomena of heat, to assume, if something must be assumed, that the atoms or molecules of a heated body, solid, liquid, or gaseous, simply repel one another or attract less, reducing their cohesion in proportion to the increase of temperature of that body; and *vice versâ*, as a body cools, so the molecules of a body increase their attraction for other molecules of the same body, while gaseous and liquid molecules increase their attraction for all other molecules, or masses of molecules or atoms.

The earth is a powerful magnet, yet it is not iron. The earth induces magnetism in every particle and mass of matter upon it, every independent molecule or atom, or mass of molecules or atoms, is an independent magnet. I do not mean that magnetism is a universal property of matter, but that all matter possesses it by induction. A few metals are capable of an excess or abnormal "charge" of magnetism. The normal condition of all matter is attractive because of the earth current induction, but as this induced attraction occurs in everything, it passes unnoticed, and we have eyes only for the excess or abnormal condition, and the artificially created magnetism or attraction produced by an electric current. We appreciate these and also any excess in the shape of lightning because it is abnormal. So that assuming every molecule or particle of matter to possess induced magnetism by induced current or otherwise normally to the extent of 100 per cent., and we are able to increase the attraction electrically or magnetically of any matter by 2½ or 5 per cent.; we perceive and appreciate this, but are blind to its universal occurrence because it is universal and normal. Does anyone suppose that in a return through the earth the operator uses that same current that entered the earth at the other end of the line?

Is there a fourth condition or form of the triune mystery, light, heat and electricity?

Now, the passage of power from sun to sun in that stupendous—no adjective in the English language is strong enough—ring is no doubt a difficult thing to swallow. But power passes from the sun to the earth, and if from a sun to a planet, why not from a sun to a sun? If not, what is it keeps each sun in its respective position in space? We know that our planetary system roughly maintains its respective position, and Sirius does not career about in space in an aimless way. We know that order is maintained. It must, therefore, be order on an orderly basis, not an haphazard order.

Now let us assume that gravitation is all sufficient. How is each sun kept in its relative position? We must again assume that the Milky-way is a ring of planetary systems. Very well, but gravitation requires a vast central mass to retain by its attraction the suns and their satellites in position. We cannot see such a body. Is it to be supposed that a mass of such a size, assuming it to be a dark body, beside which our sun must be a pigmy, could remain unseen even with the naked eye at night, with a thousand suns throwing their light upon it? And is it at all consistent with our ideas of a great centre of power and motion, such as the suns are, or in accord with what one's idea of the centre of work and energy would be, that it should be cold and dark. The judgment rejects it.

True, dark bodies attract, but it is only by means of energy derived from some other body. For, however you may regard it, attraction is work, attraction implies energy. Conceive a steam engine giving power without fire in its boiler. Conceive any work without heat or an electric current.

I must apologise for the length of this letter, but as I have before said, it seemed to me to be time that we got below the roof of the Castle Gravitation, even if we never reach the foundations.

Manor-road, Teddington, October 30th. J. D. Roots.

### LABOUR AND LUXURIES.

Sir,—I am glad to see that your correspondent "Y. X." has sufficient sagacity to discover that I consider that "political economy" should take account of morals and ethics. But he evidently has not gone through the course of study which I advised, or he would not say that writers on the subject "do not assert that these affect the science in any way."

"Y. X." says that it is of no consequence to a shopkeeper whether he trades with a murderer or a honest man. Now, it seems to me that if the murderer has already killed his fellow-workman for his money, it is at least possible that when this supply is exhausted he will take the life and property of the shopkeeper, which will be of considerable consequence to him. Again, I must presume that "Y. X." thinks that this community would be "better off, on the whole," if we were to allow all our old and infirm people to die of starvation. I suppose he is ready and willing to take his turn when the time comes. As to the words "men are simply distributors of gold. They work to obtain their turn in the use of it, and then to pass it on to someone else who has it in his turn." Does "Y. X." include under this head Socrates, the Apostle Paul, Milton, Cromwell, Wesley, Livingstone, and countless others. Further, if this is true, why do men desire seats in Parliament, baronetcies, or Victoria crosses? Herein is the point where "Y. X.'s" political economy fails. Men cannot and will not live by gold alone, and any science (?) which takes for its hypothesis that they will is useless and delusive. Hirn.

Owens College, October 30th.

Sir,—If "Y. X." were a more careful student of the writers he recommends to others, he might not have blundered into the strange assertion that a science, which has for its subject the laws of the production and distribution of wealth, views with equal indifference the manner of its acquisition and the way it is spent—not to speak of the more commonplace fallacy of identifying wealth and money. Ethics and sentiment apart, political economy takes note of crime as a condition unfavourable to production. The neighbourhood of a robber chieftain is apt to lie waste; and when the murderous B., having devoured A.'s earnings, proceeds to supply the needs of another Saturday at the expense of a second industrious life, the local tradesman will begin to notice the difference. When a king levies ship money, is it all one in the day of battle whether he spend it in maintaining a navy or lavish it on prodigal favourites? Or take a case in which there is no question of gold or silver. A Pharaoh of old Egypt, rich in great store of corn and onions, is it all one whether the serfs who consume the food be set to build a pyramid or to labour on that system of irrigation which fertilised the land?

Or, to come home to ourselves, is it all one whether the toolsmith to whom I shall pay two sovereigns or so next Saturday is a craftsman who has rendered value for value or a botcher who has spoiled good steel? Neither in fact nor in theory is it true that economic man is a mere agent for distributing gold, except in the sense that a railway is a distributor of wagons. The wagons and the money are alike part of the machinery of distribution, and the ultimate interest of the community lies in the production and consumption of goods, not in the mere circulation of wagons or gold. Gold is not even co-extensive with the money of a country, which for the most part is now-a-days documentary, and representative of a claim to a certain part of the wealth of the country, expressed for convenience in terms of gold. Now, as things are, the holders of money possess the power of determining the direction of the productive powers of the country, and each in his degree can determine to the extent of his own holding whether that productive power shall be so exercised as to increase or diminish the total wealth of the community. It is therefore by no means a matter of indifference economically how money is spent. Everything that is expended by the Government is subtracted from the spending power of individuals. The more labour Government employs, the less can individuals employ.

On the other hand, apart from sentiment, fixity of employment is economically desirable; and in Government employ unnecessary fluctuations are just cause of complaint. To diminish fluctuations and facilitate the transfer of labour, at the same time eliminating the unfit, is perhaps the most urgent problem of the day. It does not help on the solution much to launch very dubious economics at the head of a labourer, who, suffering undoubted if unavoidable hardship, expresses his annoyance with somewhat more picturesqueness than scientific precision. As to what constitutes luxury, I incline to include flowers among necessaries; the line cannot be drawn narrowly. In any case, wasteful extravagance does not benefit the labourer. "Y. X." must clear up his monetary theory, and then he may realise, to quote a recent lecture of Professor Nicholson's, that "there is nothing more false than the opposition drawn between political economy and common-sense morality."

October 30th. W. A. S. B.

### TRACTION ENGINES.

Sir,—It would be very interesting to have all the charges against traction engines put into such a form that answers from owners and others interested in their use could be put so that a fair opinion could be formed. If the preponderance of evidence were against the engine, then let an Act be framed prohibiting their use entirely—either for agricultural purposes or road hauling. If, on the other hand, the traction engine—which has grown in large numbers even under the present prohibitive Act—was found to be a useful member, and one which was rendering good and economical service to society, then I say an Act to aid its further use should immediately be framed. The highways should be free at all hours for the passage of engines on any portion of the roads. Bad bridges, drains, &c., that were damaged by the passage of engines, should be made good at the expense of the Highway Authorities, and not by the engine owners; and further, if it were known that owners of shying horses—there are still some—which are very dangerous in streets, could not get such excessive damages, then fewer accidents would occur, as from my experience in nine cases out of ten the drivers of such horses could prevent them. That the traction engine, even in its present form, is performing very useful service every day cannot be denied by even its strongest opponents. All that is required for traction engines is fair play and no favour. Assuming the engine is allowed to travel at the same hours that horses do, it would very soon prove to be the most useful, economical, and humane system of cheap transport that can be adopted. Under the present county and borough bye-laws, engines are only allowed to travel during certain hours, in certain streets, and then only certain kinds of inefficient wheels are allowed by law, which wheels do such enormous damage, so surveyors say.

I will quote an instance. In a certain large town when a heavy piece of machinery has to be removed in an engineer's works, simply from the foundry down to the weighbridge, and then into the machine shop, this is done by, say, 10 a.m., and the engine dare not stir out of the works again until 5 p.m., how is it possible to avoid accidents when engines are only allowed to travel at times when the heaviest town traffic has to be faced, and men having had to waste their time for eight hours of good daylight? Many men would wait in public-houses, as they cannot remain in the street in all weathers. Further, how can traction engines be feeders of railways if restrictions such as I have quoted exist, so that they cannot get to the railway before closing time? My own experience after very many years' use of traction engines—as well as horses—is, that if only fair play is allowed to traction engines, for heavy work horses would never be seen moving the heaviest loads. The saving to the community would be very great, if only in reducing the amount of foreign food imported for horses, and the Society for the Prevention of Cruelty to Animals would do more if they would assist to get the Road Locomotive Act altered, than they do by hundreds of miserable prosecutions such as are undertaken at present. With a practicable Act of Parliament we should soon see a proper road locomotive appear, and the agricultural type disappear; it has done wonders, but that it is perfect for heavy haulage is more than any user can say. I. W. B.

Ashton-under-Lyne, October 27th.

### THE THEORY OF THE STEAM ENGINE.

Sir,—Professor Smith in your last issue appears to be hovering dangerously near the domain of metaphysics. I would, however, recall to his recollection that Clausius bases his exposition of Carnot's theory on the postulate that heat cannot be transferred from a hotter to a colder body without the expenditure of an equivalent in work. Surely, then, the reverse statement may be expected to hold, viz., that heat cannot pass from a hotter to a colder body without work being gained in some form or another. Professor Smith's statement that the "abstraction, not the supply, of heat" is that which "is really effective in producing" "mechanical power," is open freely to adverse criticism.

Personally, I have no sympathy with those who undervalue Carnot's work; but if Professor Smith can show how, by any means whatever—whether practically realisable or no—consistent with the employment of a working substance receiving and giving out heat cyclically, a greater amount of mechanical work can be performed in return for the passage of a given quantity of heat from hotter to colder bodies, he will have a better right to dispute the right of Carnot's reversible heat engine to the title of "Perfect" than he at present has. Henry Cherry.

21, Festing-road, Putney, S.W., October 27th.

Sir,—I confess that I have read the letters of Professor Alexander and Professor Smith with the utmost amazement. I have rubbed my eyes, and asked myself, "How can these things be?" I could understand Mr. Cross or "common or garden" engineers writing thus, but to be told by, not one, but two professors of engineering that the text-books are all wrong, and that we have for the most part to learn our thermodynamics of heat engines all over again, is indeed an eye-opener. But is this all true? Are Professors Smith and Alexander authorities on such matters on whom we can implicitly rely? I would ask Dr. Lodge for guidance, but that I see from one of your evening contemporaries that he is engaged just now in investigating table turning, as carried out by Miss Eusapia Palladino in one of the Hyères Islands. Truly this is a wonderful age.

The general effect produced on my mind by such letters as those of Profs. Smith and Alexander is that something very like a direct spirit of confusion has prompted certain men to write aforetime about heat. It cannot be possible that *all* the authors of text-books have been ignorant of the truths which your correspondents now put on paper. How long is it since Prof. Smith, for example, found out that Carnot's theorem represented nothing in heaven above or in earth beneath, save a species of mathematical phantasy? How long is it since he learned that it has no manner of application to any real heat engine? Did he know this a year ago, or two years ago, or not until last week? If the discovery was made long since, why has he held his peace about it so long? If he has only just found it out, how did he chance on the discovery? Precisely the same questions may be put to Professor Alexander; and as I have asked so many, may I put one more and beg either or both of the professors to refer me to some work where I shall find a theory of heat engines which really and truly does possess some practical utility, and is not marred by the astounding blunders which Professors Alexander and Smith have tardily set themselves to correct. And, Oh, *what* does Mr. Cherry think of it all? Why it actually seems that Mr. Cross may be right after all. Ttaw.

Soho, October 29th.

### PIVOTED ARCHED BRIDGES.

Sir,—In your article on the above in last Friday's Engineer it is stated that, "The practice among engineers of hinging the ends of solid arched ribs is comparatively very modern," and quote among others, Southwark Bridge as having fixed skewbacks. I think, however, on further inquiry it will be found that though these arches are not hinged as ordinarily understood, Rennie adopted a device of very much the same effect, forming the springers in such a way that whilst apparently furnishing a bearing for the whole depth of the rib, there is actual contact over a very narrow breadth only, thus ensuring delivery of the thrust within narrow limits as in a true hinge. W. H. T.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

**** In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

**** We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

**** All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. S. (Langton)—*The North of Ireland carriage is carried on two four-wheeled bogies.*

### GRANITE, STONE, AND MARBLE QUARRIES.

*(To the Editor of The Engineer.)*

Sir,—Does any reader know a work giving the locality of granite, stone, and marble quarries throughout the world? If so, I shall feel obliged if he will kindly furnish me with the name of the publisher of same.

P. T. J.

Burnley, October 25th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* | £0 14s. 6d. |
| *Yearly (including two double numbers)* | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* | £0 18s. 0d. |
| *Yearly* | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* | £1 0s. 3d. |
| *Yearly* | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

**** The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary," and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

Institution of Electrical Engineers.—Thursday, November 8th, at the Institution of Civil Engineers, at 8 p.m. Papers: "Notes on Electric Tramways in the United States and Canada," by H. D. Wilkinson, member; "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by R. W. Blackwell, foreign member, and Philip Dawson, associate.

Royal Institution.—Monday, November 5th, at 5 p.m. General monthly meeting.

Society of Engineers.—Monday, November 5th, at the Town Hall, Westminster, at 7.30 p.m. Adjourned discussion on the paper on "The Utilisation of Town Refuse for Generating Steam," by Mr. T. W. Baker.

London Association of Foremen Engineers and Draughtsmen.—Saturday, November 3rd, at Cannon-street Hotel, at 7 p.m. Paper: "Drilling Square and Angular Holes," by Mr. Andrew King.

# THE ENGINEER.

*NOVEMBER* 2, 1894.

## THE BOARD OF TRADE AND LIGHT RAILWAYS.

A fortnight ago we directed attention to the action of the Board of Trade in the matter of light railways. Whether or not our words have stimulated the authorities, we cannot pretend to say; at all events, the publication of our article has been very closely followed by the issue of a circular—everything seems to be done by circular now-a-days—by the Railway Department of the Board of Trade. This circular acknowledges the existence of a movement recently set on foot with the object of obtaining further powers and facilities for the construction of light railways and steam or electric tram-roads, and suggests that a conference be held at the Board of Trade on an early day for the purpose of considering:—"(1) How far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely populated and agricultural districts; and (2) Whether additional legal facilities for obtaining powers to construct tram-roads and light railways are necessary or desirable." We shall not at present discuss the latter question, because it appears to us that there can be but one answer. Any modification of the law which will make the obtaining of an Act less costly than that process is now must be desirable. The only precaution needed is to see that the construction of a light railway shall not inflict an injury on any individual without providing that he shall receive suitable compensation. Care ought also to be taken that the promoters of "wild-cat" schemes shall not be afforded opportunities for robbing the public. The first question is one of far more general importance, and possesses a special interest and significance for many of our readers.

At the outset we may reasonably ask why the officers of the Railway Department of the Board of Trade find it necessary to consult with ordinary civil and mechanical engineers, traders, contractors, and others, as to how far the authorities can be justified in relaxing their rules? Surely the inspectors of the Board must already know all there is to be known about the working of every type and class of railway under the sun. All the gallant officers are past middle life, and have had years and years of special experience on such matters. How can they look for enlightenment to those who are outside their own ranks? Is there not a danger that if they appeal to others they may be misled, and induced to do that which they would subsequently have reason to regret? Thus, for example, if a line were not adequately fenced, a pig might be run over, or even two pigs. The theory that the Railway Department of the Board of Trade really does not know anything about light railways, and that the conference is to be held for purely educational purposes, is so ridiculous that it only needs to be stated to secure its rejection. But these reasonings, and conclusions, and deductions only leave us more puzzled than ever as to the object the Board has in suggesting the conference. The rules and regulations of the Department have, it is well known, been framed with great care—at least that is what we have always been told. But surely it is not too much to expect that those who prepare them and administer them understand precisely why, how, and where they apply, and how, why, and where they do not? Thus, for example, it is obvious that the complete block system should be established on our great main lines; but the inspectors must know that nothing of the kind is needed for the narrow gauge line between Slopperton-on-the-Marsh and a junction with a branch of the South-Northern road. The little line of ten or twelve miles is traversed by only three trains each way in the day, all mixed. Surely a conference is not needed to decide whether a 45 lb. rail can carry a 15-ton locomotive supported on six wheels and running at twenty miles an hour? These, and indeed nearly, if not quite, all the constructive or mechanical points that can be raised ought to be perfectly familiar to the officers of the Railway Department. The more the circular is thought over and pondered, the more puzzling does it become. The only solution of the difficulty is that about light railways the Department knows nothing and wants to learn. Some light was thrown on this point at the Conference of the Iron and Steel Trades Association held on Tuesday. We may say here that the proceedings of this conference were in general quite devoid of interest. Mr. Jeans, however, read the report of the special committee on light railways, and Mr. Hopgood, of the Board of Trade, who was present, said that in the event of any practical schemes being brought forward the Board of Trade would further as far as possible adequate inquiry into the subject of light railways; but practical schemes had not as yet been brought forward. The President of the Board of Trade had stated that the time had arrived when the Board might take steps to acquire by means of a formal conference to be held at the Board of Trade offices all information which could be afforded by those who were interested in the subject of light railways.

If this be the case the circular may be taken as a manifestation of a highly laudable frame of mind. The Department says:—"Here are a number of worthy folk who want light railways. We do not know much about these things ourselves, but we believe that they are very cheap and nasty, certain to kill people, and to prove general and particular nuisances. However, we must give way to the popular desire. We must obtain some information, and for that purpose we cannot do better than have a Conference." This is all very well so far. It remains, however, to be seen whether the speakers at the Conference can succeed in persuading the Department that excellent service may be done by little 2ft. 6in. roads laid with a charming disregard of much, if not all, that the Department deems essential. It may be useful to call attention to the circumstance that abroad 40-ton engines are carried not unsucessfully on 56 lb. rails, the sleepers being laid on the ordinary earth, no attempt whatever being made to ballast the road with gravel or broken stone, or other material of a proper and sufficient kind. It is possible, however, that after all, the words which we have quoted from the circular have a somewhat different meaning from that which they ostensibly convey. The Board of Trade may take a position which is best expressed by the word condescension. The Department may say, "We have drawn up certain rules which are altogether good. That is our affair. You assert that they interfere with the development of much needed means of transport. Perhaps so, but that is your affair. We are, however, willing to talk the matter over with you, in order to find how little relaxation of our rules you will be content to accept." This is quite intelligible, and it will be seen that it involves no assumption of ignorance on the part of the Department. It remains now to be seen whether the circular will elicit a sufficient response. We hope that such evidence will be adduced as will leave the officers of the Department no grounds for enforcing unnecessary restrictions. These restrictions may be of a double character. They may insist on such excellence of construction as would entail a prohibitive capital expenditure, or they may insist on the observance of traffic regulations which would very greatly reduce the utility of narrow gauge roads. We trust that those attending the Conference will be prepared to resist the Board of Trade on both points should the necessity arise.

Apart altogether from the action of the Board there is much that might be discussed with great benefit at such a conference as that suggested. For instance, it is by no means certain that any very great benefit is to be gained by laying rails 2ft. 6in. or 3ft. apart instead of 4ft. 8½in., and there are undoubtedly many objections to the narrow gauge for agricultural purposes. Farm produce, if we except grain, is generally bulky; and the rolling stock of a 2ft. 6in. road does not lend itself readily to the conveyance of fat bullocks. In mineral districts the case is different. There is a great deal to be learned yet about light railways, and certain popular prejudices concerning railway work in general must be abandoned if they are to be as useful as is desirable. But it is above all things desirable that exaggerated notions concerning what they can do should not be formed. Under no circumstances is it likely, for example, that goods or passengers can be transported over such roads at rates as low as that which obtain on great main lines. We can strongly recommend to our readers interested in these questions a paper on "Light Railways in New South Wales," by Mr. Charles Ormsby Burge, M. Inst. C.E., read last December before the Engineering Section of the Royal Society of New South Wales; and we cannot better conclude this article than with the following quotations from Mr. Burge's paper:—"The people of a district to be served must be content with slower speed, irregular running to time, less accommodation at stations and goods sheds, and, notwithstanding getting less, they must be prepared to pay more than those using the main lines, to cover the extra cost of working. . . The conclusion, therefore, which this paper maintains is that, generally, considerable cheapening of branch line construction can be made by lessening requirements and by improved locomotive design; but that there is a limit beyond which any considerable cheapening in capital expenditure will be more than overbalanced by excessive working expenses. An attempt has been also made to indicate what that limit is, as far as can be done, without having the ever-varying circumstances of each particular project in view." Mr. Burge's great experience and moderation of expression entitle his views to very careful consideration.

## STEAM ON COMMON ROADS.

From time to time efforts are made in a hesitating fashion to obtain such changes in the Highway Acts as will facilitate the use of steam on common roads. The law as it stands prohibits the use of steam-propelled pleasure carriages, and it grievously hinders the use of traction engines. Unfortunately, up to the present the owners and users of traction engines have proved themselves to be but weak and feeble folk, and nothing whatever has been accomplished. The history of the existing Act is a history of mistakes; and the builders of traction engines have to thank themselves principally for its harshness. As far back as 1862 traction engines were permitted to run about the country as they pleased. There was a grave doubt as to whether they could be made to pay turnpike tolls. It was understood that if any owner of a traction engine frightened horses or caused damage, he would have to pay a suitable sum in compensation. For different reasons, however, opposition was set on foot, and the traction engine builders and owners gave way, and instead of standing out for good terms took what they could get. The result was an Act of Parliament of the most oppressive character—one so full of pains and penalties, and restrictions and limitations, that it is remarkable that it did not kill the traction engine outright, as no doubt was intended by those who framed it. The fact that in spite of this traction engines are still built and used in this country supplies splendid testimony to their utility and capacity for doing good service. It is time that a change was introduced, and that steam on the common road was permitted to discharge the duties of which it is capable.

The objections to the use of steam on highways are in the main twofold. The first is that the traction engine frightens horses and is dangerous to human life; the other is that it injures the roads. As regards the first point, the argument is precisely that which has been urged not only against railways, but against steam, cable, and electrically worked tramways. We may put railways on one side and consider the facts. It is quite lawful to use a cable car drawing a tramcar up to a speed of eight miles an hour in a town. There is no red flag needed in front, nor, indeed, any other special precautions. Why should it be illegal to use a steam-driven vehicle on the same highway? Are we to seek in the rails the explanation of the puzzle? Would it be possible with the existing Traction Engine Act in force to obtain an Act of Parliament for a line of steam-driven omnibuses between, say, Westminster Bridge and Croydon? It is certain that the engines could be so made that they would give out neither smoke nor steam to alarm horses. The cable cars are passed by thousands of horses every day with perfect equanimity, and there is no reason that we can see why the steam car should not prove equally inoffensive. Any day and every day steam rollers may be seen at work in the streets of London. There is no trace of either steam or smoke, and horses take no notice of them. The greatest nuisance about them is the noise the rollers make, but that is in a sense part of their duty. The red flag business has been reduced to a farce. There is a boy, or even two boys, but the red flag might just as well be stuck on the engine chimney. One of the curiosities of the matter is that it is more than doubtful if the authorities have power to interfere with vehicles propelled otherwise than by steam. Some years ago an attempt was made to stop the use of tricycles, the "safety" was not yet born—but that came to nothing. Recently electrical omnibuses and parcel vans have run in the streets. No attempt has been made to bring the law to bear against them. Is it clear that a man running a phæton propelled by an oil engine could be stopped? It is certain that he could not run a steam engine until he had paid £10 for a licence, and then not without a boy a hundred yards in front with a red flag, and the speed must not exceed four miles an hour. All this seems childish, but it is true, and from first to last these regulations have been framed on the theory that horses must of necessity be frightened out of their wits by a steam engine on a common road or in a street.

The second argument, that traction engines ruin roads, is one worth discussing. The facts can be easily reached, but they must obviously vary with each special case. Traction engines are employed, for instance, in Kent in drawing manure to the hop gardens. Now the question presented for solution takes this form:—Is the damage done by an engine and a couple of wagons greater than the damage that would be done by horses and carts conveying the same weight of old woollen rags, &c., over the same ground? The answer will, we think, depend on the road. If that is well bottomed and properly kept up the engine will do much less harm than the horses. On a weaker road the contrary may be the case. The surface mischief will be greatest where horses are employed, but the engine has no doubt a capacity for finding out weaknesses in a road of which horses cannot boast. But even if it be conceded that the balance of evidence is against the engine, the difficulty admits of being readily overcome. The money paid for the annual licence could be devoted to the maintenance of the road. If the mechanical facts are sifted out it will be found that the law was based on the theory that the traction engine must be a noisy, clanking, puffing, smoking nuisance, to be discouraged as much as possible. No doubt time was when this theory was sound. At the present moment engines may be found which are in the most abominable sense of the word a nuisance. Yet there is no difficulty in building engines which are nothing of the kind. But there is nothing to be gained by doing this; the aid of Parliament was indeed specially invoked to prevent improvement. Whether an engine is noisy or ugly or not makes no manner of difference so long as it complies with the law, and consequently the better types of engine have been principally intended for use abroad.

It is better, having stated an evil, to suggest a remedy, although it is not indispensable that we should do so. The proper course seems to us to lie in modifying, not in repealing, the Highway Acts so far as they refer to the use of steam. Thus, for example, the use of any self-moving engine weighing more than ten tons, unless it be a steam roller, might be prohibited, on the ground that a greater weight ought not to be put on country bridges. Again, it might be settled that engines whose wheels did not each carry more than 1½ tons might run at a speed of nine miles an hour in the country and at six miles an hour in towns. For all engines or self-propelling vehicles licensed to run at the higher speeds, the use of the red flag to be unnecessary. As a matter of course, neither steam nor smoke must be emitted in a town. In every and any case the owner would be liable to an action for damages if his engine did mischief in any way—as by frightening horses, &c. Certain privileges might be conceded to engines specially contrived to avoid giving offence. In fact, the law as it stands is so one-sided and defective that nothing is much easier than to suggest improvements on it. One immediate result of a change would be, we think, that the use of steam for hauling purposes on common roads would be rapidly extended. It is argued all round us that *the* want of the age in this country is cheap transport; but transport by steam, it has been abundantly proved, is cheaper than transport by horses. No doubt the traction engine could be extensively used as a feeder to the railway if only suitable facilities were afforded for the purpose, and again improved engines capable of travelling at speeds of, say, six miles an hour, could be introduced. They have existed before in this country and did excellent service, and there is nothing but the Act of Parliament to prevent us from having them again. But besides the traction engine proper we should have self-propelled vehicles for the conveyance of passengers, and pleasure carriages. We have fully reported what has recently been done in France in this direction. If any of our readers can lay hands on Herbert's "Dictionary of Engineering," a work published nearly half a century ago, they will find in its pages ample evidence that the problem of successful passenger locomotion on common roads was worked out long since. Indeed, Sir F. Bramwell's paper read this year before the British Association, and published in full in our columns, can leave very little doubt on that point. French engineers have no doubt recently done very well. We venture to think that if English engineers were allowed a free hand they would do very much better.

◆

### TELEGRAPHY WITH AUSTRALIA AND THE EAST.

THE result of the working of the experimental lowering of the rate of cablegrams to Australasia is shown by the statement of the Eastern Extension—Australasia—and China Telegraph Company. It may be remembered that in the first year of the working of the guarantee under which the charges were lowered there was a loss of £55,040 to be shared amongst the guaranteeing Colonies and companies. In the second year there was an increase of traffic that brought down the loss to be so shared to £43,558; and now for the third year the loss is officially stated to be £12,384 only, to be shared in a similar method—one-half amongst the Colonies and one-half amongst the telegraph companies concerned. The bringing down to so small a sum is not entirely due to the increase of traffic, for it may be remembered that the Colonial Governments desired a slight addition to the tariffs to lessen the loss, and hence the increase in cost of 9d. per word has had much to do with the limitation of loss; and with the great depression in trade that has been known in the Colonies in the past year it may be fair to assume that it is to the increased cost more than to the continued growth of the use of the cables that the recent limitation of the loss is attributable. Still, there is an increase in telegraphy that must soon wipe away that loss, which is to the whole of the guarantors so small now, both from enlarged use of the cables, and from the tapping of additional feeders of the system. The value of the telegraphic communication with the Far East is known now, even with the censorship that seems to prevail, and it is probable that one result of the war that is raging will be to open out much more rapidly that great part of the East from which it has been shut out. To many parts of the East the system of cable communication has been so improved and strengthened by duplicate and triplicate cables, that whilst at the opening of communication the time occupied in transmission averaged ten hours to Australia, it is now effected in less than two hours; whilst to India thirty-five minutes is the average time, instead of five hours as at the opening of the line. There is now not only a rapid but also a sure basis of communication that is afforded by alternative routes and cables, and which must be expected to be increased. As the area for the collection of traffic is augmented by the opening out of new lines, so the receipts of the companies must be enlarged; and that enlargement could be aided materially by the guaranteeing by the Governments of the loss through reduction of the rates of charge—a guarantee which experience shows to be heavy at first, but to be reduced from year to year as the cheapness of telegraphy induces a larger use of its powers of quick communication.

### THE PARIS METROPOLITAN RAILWAY.

THE project of M. Barthou, Minister of Public Works, for constructing a metropolitan railway in Paris, is meeting with general favour by those interested in the carrying out of the undertaking. M. Alfred Picard, the Commissioner for the Exhibition of 1900, approves of the scheme, and says that the work ought to be put in hand next year, as it would be very undesirable to have any works in progress during the period of the Exhibition. The railway should be terminated at the earliest possible moment, so that the workmen should be free to be engaged upon the Exhibition buildings. He thinks it is absolutely essential that none but smokeless engines should be employed upon the Metropolitan, and in his capacity of inspector-general of the Ponts et Chaussées, he has already insisted upon the adoption of some such system upon the new extension from Molineaux to the Esplanade des Invalides. Since the project of M. Barthou was presented to the Municipal Council, it has been discussed by a committee appointed for that purpose, and criticisms have been passed upon the proposed two transverse lines, on the ground that they would not serve some of the districts in which several members of the committee were interested. The chairman also thought that the Council should have more authority over the Metropolitan than the Government seemed inclined to give them, especially in view of the fact that not only were the Council to make a grant of the land required for the construction of the lines, but they had to allow the free entry of the material used in the construction of the railway. It was feared that this latter condition would only be made the precedent for a claim by the Government to have the material to be used in the erection of the Exhibition buildings introduced into Paris free of octroi duty, in which event the Council would lose a revenue of several millions of francs. Another objection raised was the supposed danger incidental to such a vast system of tunnelling, as some members asserted that the disturbance of the subsoil might result in the spreading of an epidemic of contagious disease. Before pronouncing definitely upon the scheme of M. Barthou, the committee is considering the many other schemes that have been brought forward for the construction of a Metropolitan, but it is believed that it will finally pronounce in favour of the proposal of the Minister of Public Works with one or two slight modifications.

### COLLIERY ENGINE MEN.

THE dispute in the coal trade regarding engine men and boiler men's wages has now been settled. A conference between the coalowners and the men took place at Sheffield on Tuesday. The men's demand was that they should be allowed to stand, in regard to wages, as they did last July, before the Conciliation Board decreed a reduction of 10 per cent. They repudiated the right of the Conciliation Board to deal with their wages on the ground that engine men and boiler men were not consulted or represented on the Board. They, therefore, handed in their notices, and for a time it seemed as though a second grave strike was imminent in the coalfield. It was ultimately agreed to withdraw the notices on the understanding that a conference between the owners and men should take place. This was the conference held last Tuesday, which was of a very protracted character. It was found impossible to prepare any resolution which would fairly meet the views of both parties, or suit the circumstances of every colliery. The owners, however, intimated that each colliery proprietor would endeavour to arrange with his own engine men and boiler men, according to the circumstances prevailing at each pit, and added that in the event of any difficulty arising the owners' committee would willingly meet a committee from the other side and try to adjust any exceptional cases. After the conference the representatives of the engine men and boiler men held a meeting, at which they recommended that the whole of the men employed in the steam trade in the collieries in South and West Yorkshire to appoint delegates, who, with two of the officials of their Societies, should endeavour to bring about a settlement. It is believed on both sides that the dispute will be amicably arranged and give little further trouble.

## LITERATURE.

*Elementary Treatise on Natural Philosophy—Based on the Traité de Physique of A. Privat Deschanel.* By J. D. EVERETT, M.A., D.C.L., F.R.S., Professor of Natural Philosophy in the Queen's College, Belfast. Thirteenth Edition. London: Blackie and Son. 1894.

THE appearance, some thirty years ago, of Dr. Atkinson's translation of Ganot's "Physics," marks an important epoch in the scientific development of this country, as we were thereby first made generally acquainted with the accurate and artistic representation of scientific apparatus and phenomena. Professor Everett's translation of the *Traité de Physique* of Deschanel soon followed, and here in many instances the illustrations were complete works of art, some of which we are sorry to miss in the present edition; this is owing to the exigencies of space, and partly also to a change of scope and plan in the English version. For while the French text of Ganot's "Physics" is still closely followed in the translation, Professor Everett has struck out an original line, and now his "Treatise on Natural Philosophy" styles itself as based on Deschanel's *Traité de Physique.* In this thirteenth edition the work has been entirely recast, with the exception of the portions relating to the comparatively stationary subjects of Mechanics, Hydrostatics, and Acoustics, and thereby previous editions are now superseded; we hope, however, to find in the next edition a diagram and description of Mr. Fleuss's effective and workman-like air-pump. The engineer will find the diagrams taken from the French version more worthy of his approval than the usual absurdities made to do duty in our English text-books; at the same time he will recognise some old paradoxes which seem immortal; for instance, the figure 26, in which the equilibrium of the lower weight is impossible so long as the middle portion of the cord is on the slant. The first principles of statics are well explained in Chapter II., but the needless conception of a rigid body is introduced, as if the theorems were inapplicable to an elastic body, say the Forth Bridge or Tower Bridge; we only require the elastic body to have come to rest for the elementary principles of the composition and resolution of forces in statical equilibrium to be employed.

The explanation of the composition and resolution of forces in § 32 would be improved, in our opinion, if the second of the two components was always kept in view, as thereby a fruitful source of error in the minds of beginners would be avoided.

The C.G.S. system of units is carefully explained, as might be expected, considering the important part taken by Prof. Everett in their introduction; but the engineer will always despise these units, as too minute for any problem except of delicate physical measurement, and he will deplore the loss of Prof. Johnstone Stoney's amendment, that the metre and the kilogramme, instead of the centimetre and the gramme, should be adopted as units; as indeed they are in reality in the working electrical units, such as the joule, watt, volt, ampère, and ohm.

But what will astonish the engineer most is the extraordinary use of the word *weight*, interpolated in the English version, but not to be found in the original French of Deschanel. Article 81 runs, "The weight of a body, strictly speaking, is the force with which the body tends towards the earth." But, strictly speaking, this is no definition at all, but a mere description of one of the qualities of matter. A mathematical definition must be such as to afford a precise numerical estimate of the measure of a quantity, and this is lacking in the above attempt at a definition. If we amend it into "the weight of a body is the *number of units of force* with which the body is attracted by the earth," we shall find that the unit of force invariably employed in this definition is the gravitation unit. Thus, if a body weighs 10 lb., it is attracted by the earth with a force of 10 lb., and it is impossible that this force should be anything different, say 9 lb. or 9 99 lb. If the author will consult the Act of Parliament on weights and measures, he will find that he is liable to a fine if he employs his definition of §91, and attempts to sell grammes by weight in dynes, or pounds by weight in poundals. Does any engineer ever use the expression of a "pressure of 150 lb. *weight* on the square inch," so carefully insisted upon in this treatise? And if he meets it, does he not mentally look for an equivalent number of pound weights of matter, directly superposed on the safety valve? The two separate qualities of matter, as measured by *weight*, are very clearly distinguished in §89 as *mass* and *gravitation*; and no objection can be raised to the statement that the *gravitation* of one gramme is about 981 dynes, or of 1 lb. is about 32 poundals; but the attempt to degrade the good old word *weight* to the mere meaning of gravitation must result in confusion and failure. No wonder Professor Kennedy, in his inaugural address before Section G of the British Association at Oxford, dwelt upon the necessity for young engineers of a mathematical course quite distinct from that obtainable in the treatises prepared by the schoolmaster and the college professor.

Part II., on "Heat," contains two valuable chapters on thermodynamics worthy of study in conjunction with Professor Oliver Lodge's striking presentation of the subject in these columns. The mysterious quantity called "entropy" is dismissed rather curtly. A popular explanation is much wanted of the properties of this function, originally introduced into thermodynamics by Clausius and Rankine as an analytical help in the integration of the differential equations.

The rapid progress of electrical science in recent years has rendered sweeping changes necessary in Part III., on "Electricity," so that this part has been thoroughly recast in this edition. Extensive changes have also been made in Part IV., on "Sound and Light." The beauty of the diagrams makes this volume very suitable for a school prize, and serves to gild the pill of hard mathematical treatment occasionally—too frequently, to some minds—interpolated in the pages of description.

---

*Theoretical Mechanics: I. Solids; II. Fluids.* By J. Edward Taylor, M.A., B.Sc., London; Head Master of the Central Higher Grade and Science Schools, Sheffield. London: Longmans, Green, and Co. 1894.

Although published as separate works, the first nine or ten chapters of these two treatises are identical. They are intended to be used by young people preparing for the London University Matriculation and for the Science and Art Department examinations, and the corresponding syllabus has been closely followed. There is a wonderful similarity in the treatises on mechanics which swarm at the present time, each adapted to the requirements of some particular examination; and an engineer will be sure to find some amusement from the unpractical nature of the diagrams and illustrative examples, showing that the author has merely copied his ideas from some other similar treatise, and has never lifted his eye from the page to look at the real articles around him. In the present treatise the diagrams are, as a rule, fairly accurate; but the engineer will smile at the figure of the man pushing at a capstan-bar with a force of one hundredweight—Fig. 24—as this would imply that the man's weight is about one ton. No wonder the Georgia Magnet astonished the world a short time ago with her feats of strength, presuming on the ignorance of the spectators that the push or pull that can be exerted depends entirely on the overhang over the toes of the weight of the body through its centre of gravity. Fig. 116 of the second system of pulleys is statically impossible. Who is to be so bold an innovator as to correct it? But a statement on page 195 of Solids wipes out the science of dynamics of the last 250 years, and carries us back to the times anterior to Galileo.

"A stone will be found not to describe a straight line, but a curve. Why is this? Because the body is acted on during each second of motion by two forces, one producing a uniform motion, the other producing a uniformly accelerated motion. They are (1) the force of projection, producing a uniform motion; (2) the force of gravity, which produces a uniformly accelerated motion. The first acts in the direction of projection, *i.e.*, obliquely, whilst the second acts vertically downwards," &c.

After this we shall expect to find that the Science and Art Department accepts the mediæval theory of the Primum Mobile, or of a dæmon who turns the crank which keeps the celestial movement going.

The author attempts to clear up the confusion between $\frac{1}{2} M v^2$ and $\frac{w v^2}{2 g}$ as a measure of kinetic energy; this he does by saying that $M = \frac{w}{g}$, but in the numerical illustrations of page 208 he finds that he is obliged to put $M = w$ to make the results agree.

In an example on page 67, it is proved that 1 lb on the earth's surface would weigh 29·3 lb. on the sun's surface; but the reverse is the truth, if the weighing is carried in a balance, of the size demanded by Archimedes, reaching from the surface of the earth to the surface of the sun. These are some specimens of the ideas which are carefully driven into the schoolboy's mind, which he has to unlearn again as fast as possible when he comes as an engineer to deal with actualities.

---

*The Electric Transmission of Intelligence, Electrical Measurements, Electricity and Magnetism.* By Edwin J. Houston, A.M. The W. J. Johnston Co., Limited, New York; and Whittaker and Co., London. 1894.

We have before us a set of three advanced primers of electricity by Mr. Houston, who is perhaps best known on this side of the Atlantic from his "Dictionary of Electrical Words, Terms, and Phrases." He is careful to explain that these are not mere revisions of his "Primers of Electricity," which were published during the International Electrical Exhibition held in Philadelphia in 1884. The public are no longer so ignorant of the principles of electrical science, and more advanced works are required. The author's position as Professor of Natural Philosophy and Physical Geography to the Central High School of Philadelphia has shown him that the student is often in doubt as to the best books with which to begin his studies. In turning over the leaves of these primers, which are illustrated, we recognise the same old cuts we have seen so many times before. The "Electric Ray" still does service; what use its properties may be to the practical electrician we cannot say. The term "standard works," as used by the author, appears to include a considerable number which we had never seen classed under that heading before; and whether the young student will be assisted in forming a trustworthy opinion is open to doubt.

The primer on "Electricity and Magnetism" attempts to cover a great deal of ground; but, from our point of view, it is a misnomer to call it an advanced primer—in fact, all three appear adapted for boys of the upper forms in day schools. The author appears to favour cramming for examinations, as at the end of each volume he gives a "primer of primers," in which he attempts to give what we may designate "tips" useful for stimulating the jaded memory before an examination. The student is there, among other things, desired to remember that a particular shaped core is known as a Krizik core; and is informed that iron is preferable to copper for lightning rods.

The volume on electrical measurements appears to us better than the one just alluded to; and the chapters upon alternating currents contain useful information. Sufficient space is given to Tesla's experiments upon currents of high frequency to give the student some idea of what is being done. The portion treating of dynamo-electric machines appears the best illustrated; and here we can appreciate how much Professor S. P. Thompson has done to elucidate the construction of the machines, as the diagrams recall the illustrations in his works.

The telephone and telegraph are described in the third volume; but, throughout all the parts, many of the cuts are so very small and indistinct that they are quite useless to give the student the least idea of what they represent. In our opinion books of this kind are called into being by the rage for examinations. The class of questions set usually range over such a wide area that the student is required to pick up a surface knowledge of a mass of things, and doubtless considers he understands the subject he has read. Teachers are, of course, but little to blame; it is the system of education to which the result is due.

---

*An Elementary Treatise on Theoretical Mechanics.* By Alexander Ziwet, Assistant Professor of Mathematics in the University of Michigan. Part I., Kinematics. Part II., Statics. Macmillan and Co. 1893.

The present book owes its existence mainly to the difficulty of finding a good modern text-book suited to the requirements of the American student. So says the author at the outset in his preface; and certainly he is right as far as our text-books on mechanics are concerned; these are written to suit academical students, and the requirements of the engineering student are completely ignored. With the characteristic spirit of innovation of his countrymen, the author breaks through the old-fashioned entanglements employed in this country to retard the advance of the student. He starts off at once with the ideas and symbols of co-ordinate geometry and the calculus; but explains the details of the analysis as he proceeds, so that once the plunge is made into the new notation, the student is rapidly carried forward instead of being kept shivering on the bank, as his less fortunate fellow students in this country. The diagrams are elegant and correct, being taken from real objects, and thus they form a great contrast to the diagrams we are accustomed to expect.

While discussing crank and connecting-rod motion in Chapter III., the author might well introduce the important modifications due to the obliquity of the connecting-rod. An elegant geometrical demonstration, due to Professor Klein, has lately been brought before our notice by Mr. Archibald Sharp. The geometrical treatment of mechanical problems, well-known to engineers of all times, has now-a days been developed into a large independent subject under the name of Graphical Statics; the treatises of Culmann, Cremona, and Sir George Clarke may be mentioned. The author gives some well-chosen examples of the method, with sufficient indications for the engineering student to practice it further on his drawing-board, the only place where the subject becomes a reality. Mr. Boys' last determination of the mean density of the earth as 5·5270 should now be taken as practically final, and should replace the rough estimate of $5\frac{2}{3}$ given in §262. The American student is to be congratulated on the possession of so admirable a text book. It is a pity that it could not supplant the antiquated treatises in use over here.

---

*The Beam: or Technical Elements of Girder Construction.* By William Lewis Baker, A.M.I.C.E. London: Chapman and Hall. 1892.

This is a pleasant little treatise on the calculation required by the young engineer in the ordinary problems which occur in connection with beams and girders of moderate span. The methods are illustrated by a series of extremely simple examples, worked out to their numerical results. The author shows thereby that the complicated algebraical formulæ which bristle on the pages of more ambitious treatises, to the terror of the novice, are not found necessary for the determination of any ordinary question that may arise; and for this the student owes him best thanks.

The elementary stresses of a beam are well explained in Chapter I., including a model demonstration shown in Fig. 8; this is attributed to Professor John Perry, but must have been in use long previously at the Chatham Military School.

## MANCHESTER SHIP CANAL.

Some of those who are or may be credited with being well informed on this subject, maintain that there is no longer any doubt as to the prospects of the Manchester Ship Canal. Month by month they find the returns of the traffic department showing a better and more promising state of affairs. The approaching completion of some of the unfinished works confirms them in the belief that many of the commercial advantages are only now becoming available. This is perhaps more particularly to be noted in connection with what may be called the ports along the line of the canal.

The canal, as our readers will remember, does not touch Warrington proper, but passes to the south of the old river bend round the Arpley meadows. The original intention was to dredge and widen the Wilderspool bend of the Mersey, and to make it into a large dock, some twenty-three acres in extent, and 26ft. deep.

As yet the scheme has not been completed; the river diversion channel to the north, from Walton Arches to Arpley Bridge, has been cut, and now passes the tidal flow up to the town and beyond, as far as Latchford old weir, and the entrance to the proposed dock from the Ship Canal is made. Any future work can thus be carried out without difficulty or delay to traffic in any way.

From Warrington to the sea there are two distinct channels, viz., the old river course and the new Ship Canal. Both are tidal, or more correctly, the canal is semi-tidal, as the entrance gates at Eastham prevent the tidal waters from falling below a certain level, whereas the river falls to low tide level without let or hindrance. It is therefore to enable small coasting craft and other vessels to pass from the river to the canal at Warrington, or *vice versâ*, at all states of the tide, that the lock referred to has been constructed.

There is, however, a curious feature which somewhat complicates the situation. Although the tide rises in both canal and river, the time of high water at Walton is not the same in both channels. This is due to the more direct modern channel enabling the tidal flow to travel quicker than is the case in the tortuous old river bed. Thus the period of high tide is earlier in the canal, and the ebb, too, begins sooner than in the Mersey at the same point. From this it follows that the lock connecting these two channels must—if it is to be available at all times—be constructed to lift either way, and to work up-stream or downstream as the tidal conditions may require. Accordingly, we find at the Walton Lock duplicate gates mitreing in opposite directions at each end of the chamber, and working by chain gearing similar to that employed in the large locks, but actuated by hand instead of water power. The lock chamber, unlike those of the canal proper, which are of concrete and blue brick, is built of old sandstone, and is 229ft. long by 30ft. wide; the depth of water on the sill at low tide is 10ft. 6in. To the south of the lock is a sluice on the Storey patent principle, having an opening of 20ft., and intended for flushing purposes. It is scarcely more than ten months since this important work was begun, and already the permanent work is completed and the lock in use. All that remains to be done is the deepening and widening of the Warrington basin.

## THE ANTWERP EXHIBITION.

### BRITISH AWARDS.

#### Metallurgy (Iron and Steel).

*Diploma of Honour.*—Palmer's Shipbuilding and Iron Company, Jarrow.

*Gold Medals.*—Cradock, Geo., and Co.; The Patent Nut and Bolt Company; United Horseshoe and Nail Company.

*Silver Medals.*—Cardiff Tin Stamping Company; Chubb and Sons; Milward, Henry, and Sons.

*Bronze Medal.*—The Steel Forging and Ball Bearing Company.

#### Large Mechanical Construction: Motive Machines, Draining, Extraction Machines, Boilers, &c.

*Grand Prix Diploma.*—Babcock and Wilcox; Galloways, Knott Mill Ironworks.

*Diplomas of Honour.*—Green, Ed., and Son; Tangyes; Temperley, Joseph.

*Gold Medals.*—Bryan Donkin and Co.; Burt, Peter, and Co.; Dowson Economic Gas and Power Company; Fielding and Platt; Smith Bros. and Co.

*Silver Medals.*—Davis and Co.; Lockwood and Co., W.; Picksley, Sims, and Co.

*Bronze Medals.*—The Frictionless Engine Packing Company.

#### Machinery and Machine Tools.

*Grand Prix Diploma.*—Thomas Robinson and Sons.

*Diplomas of Honour.*—Barnett and Foster; Linotype Company; Smith and Coventry.

*Gold Medals.*—The Central Cyclone Company; Sowden, David, and Sons; Stevens, Thomas; the Hardy Patent Pick Company; the Steel Forging and Ball Bearing Company; Wilson Brothers.

*Silver Medals.*—Copley, Turner, and Co.; Leggott, W. and R.; Sagar, G., and Co.; United Horseshoe and Nail Company; Tilghman's Patent Sand Blast Company.

*Bronze Medals.*—Miller and Richard; Dermantine Company.

*Honourable Mention.*—Musto, J. J., and Co.

#### Railway Plant.

*Grand Prix Diploma.*—Westinghouse Brake Company.

*Diplomas of Honour.*—Lancashire and Yorkshire Railway; London, Chatham, and Dover Railway.

*Gold Medal.*—Patent Nut and Bolt Company.

*Bronze Medal.*—Skelsey, Geo. Henry.

#### Armoury.

*Gold Medals.*—Eley Brothers; Schultze Gunpowder Company.

#### Small Machinery. (General.)

*Diplomas of Honour.*—Chubb and Sons, Lock and Safe Company; North's Typewriting Manufacturing Company.

*Gold Medal.*—Thos. Robinson and Son.

*Silver Medal.*—The Cyclostyle Company.

*Honourable Mention.*—Leggot, W. and R.

#### Piles, Dynamos, Electrical Transmissions, Lighting, &c.

*Gold Medal.*—Crompton and Co.

#### Telegraphy, Telephone.

*Silver Medal.*—Ander's Telephone Company; Chubb and Sons.

#### Heating and Ventilation.

*Diploma of Honour.*—Wilson, Charles, and Sons.

*Silver Medal.*—Dowson Economic Gas and Power Co.

*Honourable Mention.*—Crawshay, F. G.

#### Lighting.

*Diploma of Honour.*—Cowan, W. and B.

*Gold Medal.*—Pain and Company.

*Silver Medal.*—Stott, Jas., and Co.

#### Bridges, Canals, Roads, Civil Architecture.

*Diploma of Honour.*—Chance Bros.

#### Shipbuilding, Armament, Equipment, and Life Saving Apparatus.

*Grand Prix Diploma.*—Armstrong, W. G., Mitchell and Co.; Cunard Steamship Company; J. and G. Thomson; Peninsular and Oriental Steam Navigation Company; Fairfield Shipbuilding and Engineering Company.

*Diplomas of Honour.*—Darlington Forge Company; Denny, Wm. and Brothers; Lloyd's Register of British and Foreign Shipping; Palmer's Shipbuilding and Iron Company.

*Gold Medals.*—African Steamship Company and British and African Steam and Navigation Company; Anchor Line; Blasberg, Eugène, and Co.; British India Associated Company; Canadian Pacific Railway Company; Castle Mall Packet Company; Chubb and Sons; Davis and Co.; Great Eastern Railway Company; Green, Joseph F.; Hawthorn, Leslie, R. and W., and Co.; London and India Docks Joint Committee; London and South-Western Railway; Orient Steam Navigation Company; Royal Mail Steam-packet Company; Silbe, Gorman and Co.; Sir Raylton Dixon and Co.; Swan, C. S., and Hunter; Thompson, J. L., and Sons; Union Steamship Company.

*Silver Medals.*—Allan and State Line; Barrow Steam Navigation Company; Brazilian Submarine Telegraph Company; Cook, Thos., and Sons; Edwards Bros.; Jeffrey, Alf., and Co.; Knott, James (Prince Line); London, Chatham, and Dover Railway Company; Pain, James, and Sons; Smith, G., and Sons (City Line).

*Bronze Medals.*—Chance Bros. and Co.; City of Cork Steam Packet Company; Clyde Shipping Company; Cochrane and Colper; Cork Steamship Company; Gibson, Geo., and Co.; Manchester, Sheffield, and Lincolnshire Railway Company; Palgrave, Murphy, and Co.; Tyne Steam Shipping Company.

*Honourable Mention.*—Blue Star Line, Carlisle and Co.; Farrar, Groves, and Co.; Henrard, Geo.; La Bandera Espagnola Hawkes, Somerville, and Co.; Pyman Bell and Co.; Trinder, Anderson, and Co.

---

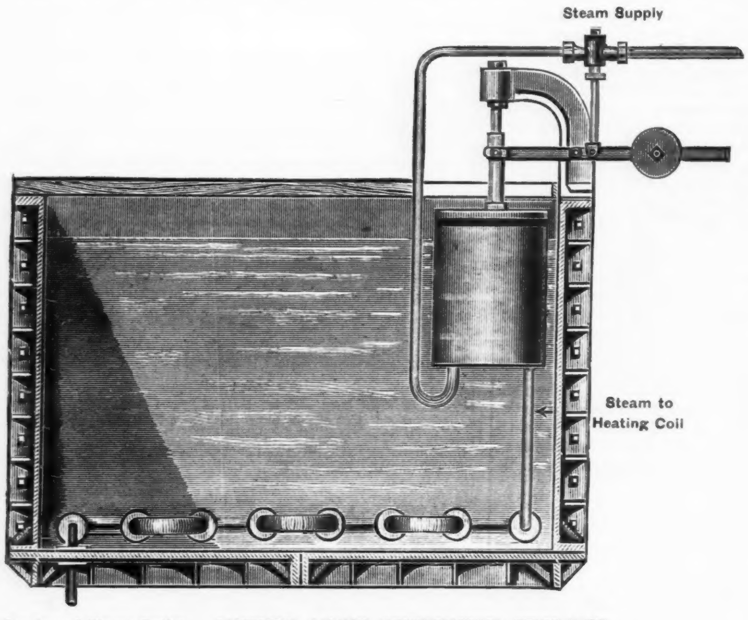
Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet Engineer W. E. Beal, to the Katoomba. Chief Engineer Quinton W. King, to the Latonia. Assistant Engineer W. W. Bills, to the Victory. Engineers—H. L. Manning, to the Pembroke; and R. W. Donohue, to the Edinburgh.

## BREWERS EXHIBITION, AGRICULTURAL HALL.

### SECOND NOTICE.

THE Farringdon Works exhibited several new appliances, which will be useful to manufacturers other than those for whom this exhibition is more especially intended. One of these, called "Mackay's Patent Hot Liquor Tank Automatic Steam Regulator," is an apparatus designed to economise the steam employed for heating hot water tanks. By its use the supply of steam is so controlled as to ensure the maintenance of any required temperature.

The regulator is a hollow metal cylinder; and, like a diving bell, is open at the bottom, but closed at the top, except that the cover is provided with a small tap, to allow the air to escape. As will be seen by the illustration, this cylinder is connected with the steam cock by means of a hinged lever, which is so arranged that if the cylinder rises in the tanks the supply of steam will be cut off, whilst if it falls it will open the steam valve. The steam on passing through the supply valve is first conducted to a small coil inside the regulator, but not in contact with it. This coil is not shown in the illustration. The pipe then goes to the bottom of the tank, and the steam having traversed the large coil, goes out by the outlet at the opposite end. A ball-cock regulates the admission of fresh water, which is so arranged that the supply pipe will deliver it on to the lid of the regulator, which just projects above the surface of the hot water. The steam, on entering the small coil, heats the water enclosed in the regulator; this gives off a certain amount of vapour, though the temperature may not perhaps exceed 100 deg. Fah. As it gets warmer, the body of vapour increases, lifts the cylinder, and eventually closes the steam valve. Meanwhile the steam, in passing through the large coil, brings the rest of the water in the tank to the same temperature as that which is in the neighbourhood of the small coil, underneath the regulator. There is a sliding weight on the prolongation of the lever which connects the regulator with the steam valve, and this will partly balance the weight of the cylinder, when water at a comparatively low temperature, say 80 deg. or 90 deg. Fah., is required in the tank. If the apparatus has to be so constructed as to allow of a varying temperature, the rod on the top of the regulator cover is prolonged, and weights are placed on it. By means of these weights the temperature of the water in the tank can be raised to any degree below 212 deg. Fah. before the vapour under the lid of the regulator will lift it, and so shut off the steam supply. When the tank has been partially emptied the fresh water which has been turned on by the descending float of the ball-cock falls on the lid of the regulator and condenses the vapour underneath it. The vacuum thus created is of course filled by water from the tank, the regulator drops and opens the steam valve. It will thus be seen that when once set to a temperature this apparatus is automatic, so that not only is waste of steam prevented, but also those using it can be sure that the water will not be any warmer than they require it.



MACKAY'S LIQUOR TEMPERATURE REGULATOR

The same firm exhibit a new system of metallic packing for steam-tight joints, which they say will stand a pressure of 150 lb. It consists of from four to six sets of semicircular pieces of steel. These pieces, which are of the exact diameter of the rod, are placed so as to break joint with one another, and are held in place by small spiral springs behind each piece.

They also show two distinct sorts of refrigerators. In both ammonia is used; but whilst one is of the ordinary description, with pumps for compressing the ammonia, &c., the other is entirely without pumps or other moving parts. This machine, like the steam regulator, is the invention of Mr. F. Mackay, and the process is based on the fact that water at an ordinary temperature will absorb a large quantity of ammonia, and give the same off when heated. Refrigerators on this system are not entirely new. Mr. Mackay's machine is, to some extent, a modification of one patented some years ago by Mr. A. Glasson, of the same firm; and Messrs. Stewart and Co., of Glasgow, also made an absorption machine, using a steam coil to heat the solution of ammonia and water. The chief novelty in Mr. Mackay's machine is in the arrangement, the rectifier being placed on the generator, and the absorber on the top of that.

The generator is an iron vessel, which is heated by a ring of gas jets; or, if preferred, by petroleum. It is filled with a mixture of ordinary commercial ammonia and water, the ammonia being about one-third of the total, and the solution is at a pressure of 120 lb. to the square inch. On heat being applied, ammonia vapour mixed with steam ascends an upright pipe in the middle of the rectifier. In this the steam is condensed by means of the cooling water, and flows back into the generator, whilst the ammonia vapour, collecting at the top, also condenses, and flows down a spiral iron pipe that surrounds the other, as liquid anhydrous ammonia, the pressure remaining the same as in the generator, viz., 120 lb. At the bottom of the rectifier is a valve, through which the ammonia is allowed to pass very slowly into a pipe which leads to the brine tank. The pressure in this pipe being only about 10 lb., the liquid ammonia immediately expands and vaporises, its temperature at the same time dropping to from 30 deg. to 60 deg. below freezing. The ammonia vapour passes through coils round the cells, which have been filled with fresh water and placed in the brine tank; and its temperature on leaving the tank is only a little below freezing. From this it rises to the absorber, which is filled with weak liquor from the generator. The process of condensation and absorption is aided by a coil with cooling water which passes through this vessel. To return the recharged liquor to the generator, the process is stopped occasionally, and a valve in the absorber opened, when it is allowed to run back by gravity down a tube outside the machine, and then through another valve into the generator. The machine exhibited consumed 800 cubic feet of gas in twelve hours, and the cooling effect was equal to that obtained by melting half a hundredweight of ice per hour, or as heat efficiency, of from 17 to 18 per cent. Where a large quantity of ice, or great cooling power is needed, it is more economical to use a compression machine; but for small factories the simplicity of the absorption machine renders it very valuable.

An ammonia compressor ice-making machine is also exhibited by the Linde British Refrigeration Company, and a carbonic anhydride machine by Messrs. J. and E. Hall.

From a mechanical engineer's point of view, the greatest change which has taken place in English breweries of late years has been in the method of cooling. The primitive plan of turning the wort out into immense "backs" or tanks, and allowing the air to cool it, has not quite disappeared, even in London, though it is gradually being superseded, or at least supplemented, by the use of cooling machines. These used formerly to be circular, the wort, passing through a spiral pipe, was met by cooling water which travelled in an opposite direction. No circular refrigerators are shown at this exhibition, and English brewers seem to be adopting the continental method, in which both air and water are used—partly by evaporation—to cool. Refrigerators of this type are exhibited by Messrs. H. J. West and Co., Messrs. S. Briggs and Co., Messrs. Lawrence and Co., and others. The apparatus usually consists in a series of copper pipes placed horizontally in an upright cast iron frame. These tubes, though circular inside, are made with a rib on the bottom and a groove on the top, running the full length of the tube, so that they fit close together, presenting a corrugated surface. The wort flows over the top, down either side, and is caught in a trough at the bottom; whilst water, either from a well or artificially cooled, is forced through the series of copper tubes from the bottom to the top. Several modifications of this system were exhibited at Antwerp, and described in THE ENGINEER a few months ago.

Besides vertical coolers, Messrs. Lawrence and Co. show a horizontal, or low-fall, refrigerator. It is the invention of Mr. C. F. Hughes-Hallett, and is intended for use where there is not sufficient height for one of the ordinary type. The one exhibited—see illustration—is 2ft. 6in. long, 4ft. 3½in. wide, and 15in. deep. It is placed on the slope, with a fall of 3in., so that the total height required is 18in. This machine is in five sections, and will, we are informed, cool fifteen barrels per hour. The cooling water is in copper pipes, flat, but corrugated longitudinally, and 12in. deep. The principal part of the invention consists in the use of a deflecting diaphragm between each of the sections containing water. These diaphragms have narrow feathers or ribs projecting opposite the corrugations in the water pipes, so that the wort may be forced into them, and have the full benefit of the cooling surface. It will be seen by the illustration that the water passes from left to right, and right to left, whilst the wort flows down one side of the coolers and up the other. The sections through which the cooling water pass are interchangeable, and if it should be necessary from any cause to remove one, the rest of the refrigerator can be used, so that the cooling would not be stopped.

Another instrument, exhibited by Messrs. Lawrence on the same principle, is the "sectional condenser" for condensing and cooling spirit. It consists of a set of corrugated sheets of tinned copper or other suitable material, each surrounded by a metal frame, faced on both sides. These sections are interchangeable, and a number of them are bolted together, the sides of the condenser being of cast iron. The vaporised spirit from the still enters one side at the top, and passes through alternate sections, whilst the cooling water, entering at the bottom, is forced through the intermediate sections in the opposite direction.

Another horizontal refrigerator is exhibited by Messrs. R. Morton and Co., of Burton. It is 20ft. long by 6ft. wide, and will cool sixty barrels per hour. The cooling arrangement is similar to that of Mr. Hughes-Hallett's refrigerator, but the diaphragms, of which there are fifty, are smooth, instead of being ribbed. This firm exhibit many other brewing appliances, including a Steel's mashing machine, a cask-washing machine, wort pumps, and a beautifully made mash tun. The washing machine consists of a cast iron receptacle communicating on one side with the steam and water supply, and on the other side with the cask. The whole process is done with one handle. In its first position it allows the receptacle to fill with cold water, the second admits steam to heat it, whilst the third injects the hot water into the cask, following it up by dry steam which drives it out again. While the cask is being removed, the handle is put back into the first position, to be ready for the next. The mash tun exhibited is of cast iron, with gun-metal rousers and false bottom. The chief novelty about it is that the sparger is self-acting, having holes on one side only of the arms, so that the falling water turns it. It is on ball bearings, and runs very easily.

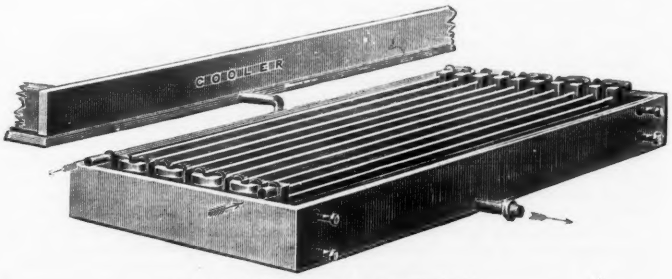
THE PRESSURE NEEDLE FILTER

The natures of different descriptions of wood, and the objects for which they may be employed, is always an interesting subject for engineers. Cedar, as a material for vat making, is comparatively unknown in England, but Messrs. Shuters and Chippendales, who exhibit some large vats and backs constructed with it, say that it is extensively used in the United States for that purpose. Railway sleepers made of cedar outlast oak, especially in positions where they are subjected to both heat and moisture; so that it is not surprising that for vat-making, it is found to be more desirable than fir or pine. The wood used by the exhibitors comes from North Carolina, and is known as "White Swamp Cedar." They say that besides being very durable, it is free from tannic acid, resin, or colouring matter, has hardly any expansion or contraction, and is not liable to crack; also that it is not affected by acids. The same firm exhibit various sized barrels, all made of oak. They do not recommend cedar for this purpose, but only for stationary receptacles, as it is too soft to withstand the treatment which a barrel receives.

Vats made of white cedar are also exhibited by Messrs. G. Adlam and Sons, of Bristol. The same firm show several other appliances used by brewers, such as an apparatus for washing and purifying a number of casks at once, but their chief novelty is "Hudson's Duplex Economiser." This machine is for the purpose of obtaining a supply of pure hot water for cask washing, boiler feed, or other purposes. It consists of two cylindrical tanks which, though separate, are for convenience placed one on the top of the other. The exhaust steam enters the lower tank at the side. Here any heavy matter in suspension, and nearly the whole of the oil is deposited. The steam—with a small oily residuum—passes by a pipe outside to the top of the second tank. On entering this, it is met by a spray of cold water, which must contain a small amount of carbonate of lime. There is no difficulty in finding hard water of this description, and if it is desired to use it for feeding boilers, the economiser has the additional advantage of being able to soften it. When the steam meets the spray, the former is condensed and the latter heated. The carbonate of lime is thrown out, mixes with the remainder of the oil, and falls to the bottom of the tank. By this means an ample supply of pure water is obtained at a temperature of 200 deg. to 208 deg. Fah.



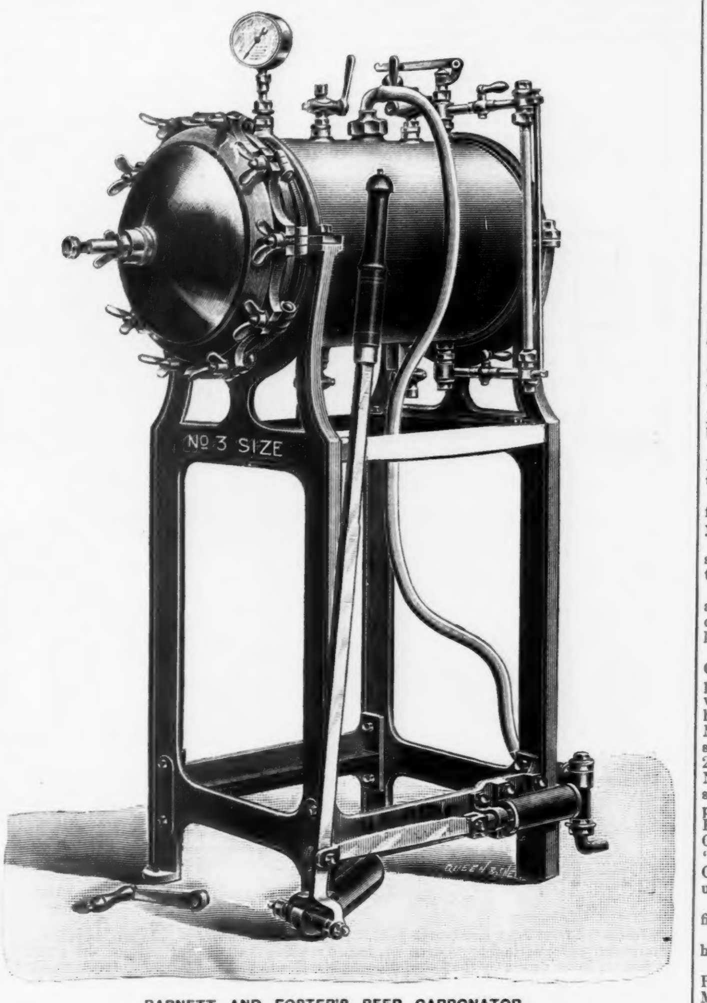
THE HUGHES-HALLET REFRIGERATOR

As pure water is an absolute necessity for mineral water manufacturers and brewers, it is natural that several descriptions of filters should be exhibited. Of these, only one appears to be new, the "Pressure Needle Filter," shown by the Silicated Carbon Company. As will be seen by the illustration, the water first passes through a strainer B, and is then partially filtered through granular silicated carbon C before impinging on the needle A. By this means the water is nearly pure before reaching the needle, and the makers claim that when it leaves the filter it is absolutely sterilised. Some of the tests to which this filter have been subjected are interesting; for instance, Professor Wanklyn writes that he has passed a poisonous solution of strychnine through it, and then drunk it. By unscrewing the nozzle, the needle can be removed, cleansed by boiling, and replaced, whilst at the same time the granular carbon may either be scalded, or replaced by new material.

The tubular fire bars made by Messrs. Caddy and Co., of Nottingham, have already been described in THE ENGINEER; but a novelty which they show at this exhibition consists in a rocking attachment. The bars are cast the whole length of the furnace, and by means of this arrangement the fire can be cleaned without using a pricker, or opening the furnace door. By raising a lever outside, every alternate bar will be lifted in front an inch and a-half, and at the same time will slide backwards about three inches; meanwhile the other bars will remain fixed. On lowering the lever, the bars move back into their original position. As this operation can be repeated without difficulty, the stoker has no trouble in keeping a clear fire, and preventing clinker from forming on the bars.

Of the subsidiary industries connected with the manufacture of aërated waters, the production of liquid carbonic acid is probably the most important. It is not so many years since the liquefaction of carbonic acid was considered to be a mere laboratory experiment; interesting, but leading to no practical result, whilst even distinguished scientists looked with wonder on a "snow ball" of solid carbonic acid. And now, thanks chiefly to the mechanical engineers who have made pumps to compress it, and bottles to hold it, liquid carbonic acid is sold by weight like any ordinary commodity, the present price being about 4½d. per lb. Each pound is equal to 52 gallons of expanded gas, capable of aërating eight or nine dozen 10-ounce bottles of mineral waters at an average pressure of 100 lb. per square inch, or of carbonating eighteen dozen bottles of beer at a pressure of 20 lb. per square inch. The Carbonic Acid Gas Company, of Lea Bride-road, show tubes containing the liquid acid, and appliances for using it. They have also lumps of solid carbonic acid at their stand, and these, notwithstanding the heat of the hall, diminished in size very slowly.

The use of liquid carbonic acid is gaining ground amongst the manufacturers of mineral waters, as it is cleaner and more convenient for them, as well as probably cheaper, to use it than to make their own carbonic acid, with whiting and sulphuric acid. It is especially useful for carbonating beer, which is then ready for use within twenty-four hours, instead of requiring to be kept till the gas had been produced and the beer matured by partial fermentation. Our illustration shows a machine for carbonating beer, which is one of a number of different sizes exhibited by Messrs. Barnett and Foster. The beer is pumped into the copper drum; in this machine the pumping is done by hand, but in some of the others by steam. The steel bottle containing the liquid carbonic acid is fixed to the machine, and connected to the drum by a regulating valve on which there is a pressure gauge. When the drum has been pumped full of beer and the gas has been admitted to the required pressure, the handle of the mixer is turned, and the beer is ready to be drawn off to the bottling machine. In some instances the gas is first charged into a gasometer, in order to have a large supply at a constant pressure. To do this without supervision, the exhibitors have just brought out an automatic valve. By the use of this valve the gas is admitted at the same rate as that at which it is drawn off, no matter how the speed may vary. On the tube becoming exhausted an electric bell is rung, so that the only attention which is required is to replace an exhausted tube by a full one.



BARNETT AND FOSTER'S BEER CARBONATOR

Another novelty is a filling machine, fitted with an automatic measuring attachment. This is intended for stone and other opaque or dark bottles, and ensures the bottle being filled with a definite and pre-arranged quantity of liquid, whatever the pressure may be, and without the operator needing to see the height to which it has been filled. This firm have also a large number of different descriptions of bottling machines for soda-water syphons, screw-stoppered bottles, &c. Two of these called the "Mammoth," and claimed to be the largest yet made, have been supplied to Kimberley and Johannisberg, South Africa.

Messrs. W. Meadowcroft and Son also claim to have made the largest soda-water machine in the world, and exhibit the "Giant," a very fine machine, which they say is capable of producing 10,000 to 12,000 dozen 10-ounce bottles of highly charged mineral waters per day of ten hours. They also show a large collection of smaller machines.

Another firm who have a very large show of aërated water machinery at work are Messrs. Bratby and Hinchliffe. Their latest production, the "Columbia" steam cork bottling machine, is a double machine, capable of filling 100 dozen per hour when both sides are being worked. A boy or girl can feed both sides, and does not require to touch the bottles after they have been once put in.

---

TWENTY-SEVEN boilers out of a battery of thirty-six, at the Henry Clay Colliery, Shamokin, Pa., exploded on the morning of October 11th. Five men were killed, two seriously injured, and four slightly. The nine remaining boilers were wrecked, although they did not explode.

---

## LEGAL INTELLIGENCE.

### HIGH COURTS OF JUSTICE—QUEEN'S BENCH DIVISION.

*October 25th*, 1894.

(*Before the* LORD CHIEF JUSTICE *and a Special Jury.*)

EARL OF SHAFTESBURY *v.* LONDON AND SOUTH-WESTERN RAILWAY.

THIS was an action by an owner of property in Dorsetshire to recover damages for the destruction of part of his property, which he alleged was set alight by the defendants through the negligent use of a locomotive on their line. The defendants denied their negligence or liability.

Sir EDWARD CLARKE, Q.C., Mr. E. U. BULLEN, and Mr. GORE BROWNE were for the plaintiff; Sir RICHARD WEBSTER, Q C., Mr. BUCKNILL, Q C., and Mr. ACLAND for the defendants.

Sir EDWARD CLARKE, in opening the case, said that the two questions the jury would have to consider were:—(1) Had the fire been caused by the defendants' engine, and (2) if "yea," had they been guilty of negligence in their use of it? The facts were simple, and were shortly these. On June 17th, 1893, a train left West Moors Junction on its way to Ringwood. The gradient was rather steep for about half a mile, and pressure had to be put upon the engine to get the train up. The train left at about 3.45 p.m., and at 4 p.m. a fire was observed to be burning three-quarters of a mile from the station just after the train had passed. Attempts were made to put out the fire, but without avail, and the result had been that 124 acres of valuable property had been burnt down. There was no footpath or house anywhere near the spot, and there could therefore be no doubt as to the originating cause of the mischief. As to the defendants' negligence, the engine in question had been in use since 1875, and although originally fitted with a "grid" to prevent sparks from coming out, this had been removed and the engine fitted with "Adams's Vortex blast pipe," which had the effect of, in fact, causing a much greater draught than before. It enabled, however, the defendants to use a much smaller engine than they would otherwise require, and that was probably the reason it was used.

Mr. A. H. Tyler, C.E., formerly in the locomotive department of the North London Railway, said he had examined the engine in question—the Milo. It had nothing to prevent an escape of sparks, and was fitted with the "Adams Vortex blast pipe," which would tend to throw up sparks on account of the increased draught. A "grid" would catch large sparks, and the use of "Adams's blast pipe" would cause sparks which would otherwise rest in the smoke-box to fly up through the funnel.

Cross-examined.—He was a pupil at the North London Railway Works at Bow from 1884 to 1887. He had never heard of a "grid" being used with Adams's blast pipe. The Adams patent claimed that it caused all the boiler tubes to act uniformly. He did not consider that the Adams patent should be used through a country liable to be set alight.

Re-examined.—The Great Eastern Railway used an adjustable blast pipe.

Mr. Fuller and Mr. Griffiths, civil engineers, gave evidence in the same direction. If a "grid" was used a stronger blast was required, and that would cause any sparks that got through the grid to travel further.

Mr. Richards, a land agent at Wimborne, estimated the damage at £1337, and Mr. Squarey, of Salisbury, at £1318.

Cross-examined.—The value of the land to sell might be from £1000 to £1200.

Mr. Wilbraham, Lord Shaftesbury's agent, fixed his estimate of the damage at £1463.

Sir RICHARD WEBSTER, Q.C., in opening the defendants' case, said that if plaintiff's view was correct, relief had at last been found for the "distressed landholder," who had only to have a good fire on his estate, and then sue an unfortunate neighbouring railway company. The law, he should submit, was now the same as in 1861, and recently Mr. Justice Mathew, in the case of "Groom *v.* Great Western Railway" (8 the *Times*, L.R., 253), referred to the direction of Mr. Justice Williams to the jury in "Freemantle *v.* London and North-Western Railway" (2 F. and F. 340). No engine had yet been invented that did not emit sparks, and the mere fact that sparks had come out did not make the defendants liable or guilty of negligence. The real question was, Had the defendants taken every reasonable precaution?

Mr. Watney, a surveyor, estimated the damage at £194.

Cross-examined: He valued the land at £4 an acre. That was an outside price, as it was situated at such out-of-the-way spot.

Mr. Harris, a Winchester surveyor, fixed his estimate of the damage at £218. In his opinion, if half the firs were replanted the plaintiff would be in a better position than he was before the fire.

At this stage the Court adjourned.

On the further hearing of this action,

Charles Oran, the engine-driver of the train which was alleged to have caused the mischief, examined, said he had been twenty-five years in the defendants' service, and during eighteen of the twenty-five years as engine-driver. On the day in question the fire was made up at Wimborne, and was not touched again until he reached Ringwood. This was after passing the scene of the fire. The engine was running at the least possible steam, and no ashes were raked or thrown off during the journey. At the end of the day the smoke-box was only half full of ashes. The Milo was not a particularly "wicked" engine with regard to giving off sparks.

Cross-examined.—This was the second occasion on which he had driven that particular engine in 1893, but he had driven it in previous years. He was four minutes late out of West Moors Junction, but he was not trying to make up time. He would start at full pressure, but after a hundred yards would bring his lever to the first notch. He passed up a gradient of 1 in 352, and was going at about 20 miles an hour when he passed the scene of the fire. There had been several fires near the line about that place and some a good way off the line. There was a rule of the company against throwing clinkers off the engine, and, indeed, during the journey they could not get at them if they wanted to.

Cornelius Spredbury, the fireman, gave similar evidence.

Cross-examined.—Removing clinkers from the fire would "clear" it, but it could not be done except when the fire was low.

William Goodwin, the guard, proved that no time was "made up" after leaving the junction.

Oran, recalled, said the "specimens" produced by the plaintiff were lumps of coke which had fallen off trucks, and were not Welsh coal such as was used on the engines. Coke would be found in the ballast on the line, as the cinders from the yards were collected and used for that purpose. The bits found within the "burnt area" were probably Welsh coal.

George Wilcocks, seventeen years a ganger on the defendants' line, said he saw the fire at about 4 p.m. He obtained help and put the fire out, as he thought, but the next day it broke out again.

Cross-examined.—He had not told Read—the plaintiff's first witness—that the train had caused the fire, or must have caused the fire.

Mr. Brewer, permanent way inspector at Ringwood, and Mr. Baines, permanent way superintendent, gave evidence as to there being footpaths near the spot where the fire commenced.

Cross-examined.—There were a good many fires near the line in 1893. Eight of these were between West Moors Junction and the scene of this fire, a distance of three-quarters of a mile.

Re-examined.—One of the fires was three-quarters of a mile from the line; another, a quarter of a mile off; and a third, 117 yards away.

Mr. Thomas Higgs, locomotive superintendent at Nine-elms, said he had tested the Milo, and after a run of 154 miles found that the smoke-box was only half full of ashes.

Cross-examined.—He did not see the plaintiff's engineers take any samples such as had been produced. The load the Milo was drawing on the day in question was only 75 tons, and with such a load a gradient of 1 in 352 was nothing.

Mr. Dugald Drummond, formerly chief engineer to the Caledonian Railway Company, whose experience extended over a period of thirty years, stated that the plaintiff's samples of coke which were picked up on the line were not Welsh coal at all, and had never been in the furnace of an engine. In his opinion the Milo was a perfect working engine, and was fitted with all that science or experience could suggest. In his opinion it could run 200 miles without requiring to have its smoke-box emptied. Nothing had yet been designed that would absolutely prevent sparks coming away from the engine. No engine with a blast pipe or modern fire-box should be fitted with a spark "arrester." He had been connected with the London, Brighton, and South Coast Railway and the North British Railway. The cost of "arresters" was nominal, and he had discarded them on the Caledonian Railway. He was not aware that they were generally used in America.

The LORD CHIEF JUSTICE.—They do not seem to prevent forest fires.

Sir EDWARD CLARKE.—I tremble to think what might have happened if they had not been in use.

Mr. Dean, chief locomotive superintendent of the Great Western Railway; Mr. Johnson, chief locomotive superintendent of the Midland Railway; and Mr. Whale, assistant locomotive superintendent of the London and North-Western Railway, all gave evidence in favour of the construction of the Milo, and against the use of a "grid" or "arrester" when the Adams Vortex blast was in use. They were of opinion that in any case they created rather than prevented sparks, on account of the stronger draught they required. Cage arrestors were used in the docks, where engines were continually starting and stopping with heavy loads. The Adams blast had been tried on the Midland, but was found unsuited to their engines. There were no objections to its use. It claimed to reduce the consumption of coal.

Mr. WILLIAM ADAMS, the inventor of the Vortex blast pipe, and locomotive superintendent of the London and South-Western Railway, having been called to explain his invention,

Sir RICHARD WEBSTER, Q.C., and Sir EDWARD CLARKE, Q.C., addressed the jury on behalf of their respective clients.

The LORD CHIEF JUSTICE, in summing up the case, said the chief question in the case was—had the defendants been guilty of negligence? Then and then only if that question was decided against them did the question of damages arise. As to that question, which he would deal with first, it ranged from £1463, the plaintiff's highest figure, to £194, the defendants' lowest estimate. At the same time they must remember that the plaintiff was not entitled to be put in a better position than he was in before the accident. The first question to consider was whether the fire was in fact caused by something which came from the engine. The fact that the other fires had occurred should not bias their minds, but they must draw their own conclusions from the evidence before them, and the fact remained that immediately after the train had passed the fire was discovered. Assuming that the fire was caused by the defendants' engine, then arose the principal question—Had the defendants been guilty of negligence or of want of reasonable care either in the construction or working of the engine? The law on this point was quite clear, that where a company had powers from the Legislature to do certain acts, they were not liable for the results of those acts so long as they acted with reasonable care. He hardly thought that they would come to the conclusion that the driver or stoker had thrown live coals off the engine, and therefore the question of negligence was narrowed down to the question of whether a "spark arrester" should have been used or not. The most recent case in the House of Lords was almost on all fours, and he would read them a portion of the judgment of the Lord Chancellor in that case:—"Port Glasgow and Newark Sailcloth Company *v.* Caledonian Railway Company"—Court of Session and House of Lords cases, volume xx., page 35, 9 the *Times* L.R., 300. In considering the question of negligence in construction it did seem to him that there was some force in the defendants' contention that a close mesh "arrester" would act as a damper and require a great extra draught. The question was shortly this—Was it negligence on the defendants' part to use the Vortex blast without an arrester? The learned judge, having carefully reviewed the evidence, left the following questions to the jury:—(1) What caused the fire? (2) Were the defendants guilty of negligence? (3) What damages was plaintiff entitled to?

The jury retired at 4.30 to consider their verdict, the parties having refused to accept the verdict of the majority. The jury returned into court at 5.15 and found:—(1) That the fire was caused by something from the engine; (2) that if an "arrester" had been used the danger would have been minimised; (3) damages, £400.

The Lord Chief Justice having left the building, the jury were ordered to attend on Saturday morning.

On the 31st ult., arguments were heard on a point of law, Sir E. CLARKE, Q.C., moving that judgment should be entered for the plaintiffs. It was distinctly laid down that a railway company were bound to avail themselves of every modern invention, unless —(1) the danger was very slight; (2) the cost of the invention very great; or (3) the use of the invention materially interfered with the working of the engine. In the present case the answer to every one of these questions was a negative. All the defendants could say was that they had saved a few pounds of coal per mile by not using an "arrester," and this they had no right to do at the expense of the public.

SIR R. WEBSTER, Q.C., for the defence said that the evidence showed that if arresters were used a stronger blast was required, which would cause more sparks. The defendants were called upon to provide "general" and not "particular" remedies, and he asked that judgment be entered for the defendants.

At the conclusion of the arguments the LORD CHIEF JUSTICE said he would take time to consider his judgment.—*Times.*

---

## SOCIETY OF ENGINEERS.

### THE UTILISATION OF TOWN REFUSE FOR GENERATING STEAM.*

By T. W. BAKER, B.A.

THE practice of the larger southern towns in England is that all fluid waste from dwellings is called sewage and its disposal is provided for in these towns by different systems of treatment; but there are even now some towns in the North where the pail system is still in use. The class of refuse treated under the latter system is not included in this paper, but what will be considered consists of the usual ashbin contents, street-sweepings, and sludge.

The disposal of the ashbin refuse and street-sweepings in large towns has been a source of considerable trouble and expense to the local authorities, and several vestries in London are now paying 3s. per ton for its disposal, exclusive of the expense of collecting it. Consequently if 70 per cent. can be utilised and barging saved, considerable economy must ensue. There appears at the present time no doubt whatever that ordinary ashbin and street refuse should be dealt with by fire at the earliest moment and at the nearest possible point, as it soon becomes a prolific source of zymotic diseases. Consequently prompt and localised destruction is particularly desirable as railway conveyance or barging causes delay and contamination to the surrounding atmosphere.

In order to better understand what ashbin contents consists of, the author appends the analysis of Mr. Joseph Russell, given in a paper read before the Sanitary Institute on February 10th, 1892, and which may be of interest, the same having been practically corroborated by several other authorities.

| Component parts. | Average per 1000 loads. Tons | cwt. | qr. | lb. | Percentages of weight. |
|---|---|---|---|---|---|
| Breeze, cinder, and ashes | 611 | 3 | 0 | 4 | 63·69 |
| Fine dust | 187 | 1 | 9 | 8 | 19·51 |
| Vegetable, animal, and various mineral matters | 44 | 3 | 3 | 20 | 4·61 |
| Waste paper | 41 | 1 | 1 | 20 | 4·28 |
| Straw and fibrous material | 30 | 18 | 1 | 6 | 3·22 |
| Bottles 5,000 | | | | | 0·96 |
| Coal and coke | 8 | 0 | 2 | 14 | 0·84 |
| Tins | 7 | 11 | 2 | 22 | 0·79 |
| Crockery | 5 | 5 | 0 | 0 | 0·55 |
| Bones | 4 | 12 | 1 | 1 | 0·48 |
| Broken glass | 4 | 11 | 2 | 2 | 0·47 |
| Rags | 3 | 15 | 3 | 16 | 0·39 |
| Iron | 2 | 0 | 0 | 20 | 0·21 |
| | | | | | 100·00 |

From the report of the London County Council on dust destructors, the average from several districts gives 260 tons per annum for one thousand of the population, although the actual quantities vary widely. Taking this into consideration, and the fact of the preponderant amount of combustible material which it will be noticed is present in this refuse, it is apparent that it should be disposed of by fire not merely with a view to its destruction for hygienic reasons, nor yet to reduce its bulk—which is done by the destructors in present use leaving only from 25 to 30 per cent. of ash and clinkers—but that the heat set free in the process of destruction should be utilised.

Professor Forbes and others have estimated the value of ashbin refuse at a much higher figure than results from practice, the various estimates ranging from 3 lb. to 5 lb. of water evaporated for 1 lb. of refuse. Hitherto in practice this result has not been obtained, and according to statistics collected by Mr. C. Jones, M.I.C.E., from the larger towns using destructors with steam generators by the waste heat, 6-horse power per cell burning from six to eight tons every twenty-four hours, appears to be the average result. This result, doubtless, can be increased by the use of forced draught, at the same time enabling the furnaces to do a far greater amount of work as destructors.

These statistics no doubt include the disposals of the street sweepings, which must be taken carefully into account, they being the vehicle for moisture impregnated with effluvia, which during destruction absorbs some of the active heat from the more combustible ashbin refuse. As the various local authorities, particularly around London, are now anxious to use their powers under the Electric Lighting Provisional Orders granted to them for laying down plant for lighting their districts by electricity, this appears to be the better and most direct method of using this source of gratuitous heat. At the same time there are waterworks and sewage pumping stations requiring steam, as well as baths and wash-houses which frequently belong to the local authorities, where the heat could be advantageously utilised.

There can be no doubt that the calorific value of the refuse is low, particularly when street sludge is used, and from results obtained by the author, only 1 lb. of water evaporated per pound of unsifted refuse is actually obtained. With screened refuse, however, that is, with the paper and loose rubbish, commonly called breeze, taken out, a fair average of 2½ lb. of water evaporated per pound of breeze is the result. For some months past the author has been using this fuel in an ordinary double-flued Galloway boiler, 22ft. long, 7ft. diameter, with twenty-two cross tubes and steam jet forced draught, the boiler being used for boiling purposes. These results could only be obtained by burning the breeze in direct contact with the boiler, and could not be so obtained if used in a destructor, and then passed through brick flues to the boilers; Mr. Jones' statistics before referred to are based upon the working of plants of the latter description.

The trouble in stoking, owing to the amount of ashes and clinkers, prohibits the general use of town refuse in boiler furnaces to any great extent. A very large boiler capacity and great area, proportionate to the quantity of steam required, are necessary, far beyond that usually required for ordinary coal burning, and further unless the refuse is mixed with coal, 60 lb. appears to be the maximum boiler pressure obtainable. Even with a strong forced draught in the ashpit 80 lb. only has been obtained. Consequently to make the use of the town refuse economical, in connection with the best modern steam engine practice, a greater heat must be available and a higher pressure attained. Moreover in thickly populated districts all escaping vapours must be rendered innocuous, so that there are three conditions for consideration, namely:—(1) Facilities for stoking and cleaning the fires. (2) Burning up the obnoxious fumes. (3) Temperature of combustion to be raised to produce higher pressures. First as regards facilities for stoking and cleaning the fires. The principle of the ordinary dust destructor in its general design is doubtless the best, viz.:—Having the feeding hopper at the upper end and the fire-bars at a lower level continuing towards the cleaning doors, and having mechanically moved fire-bars bringing the refuse forward, allowing the green fuel to be gradually brought towards the fire, thus evaporating and burning up the moisture in it. Of the several designs of different makers, that known as Healey's appears to be a good type, and most advantageous when used with a forced air draught, although there are several other designs which are equally applicable, viz:—Fryer's, Horsfall's Wiley's, and Warner's.

In Healey's furnace the hearth plate is at an upper level, on which the refuse is fed, and which in its descent, travels on to a movable gridiron and from thence to the fire-bars proper. In order to keep the furnace at its full work this continual feed is necessary; but Healey's movement of the furnace bars has the triple effect of feeding the furnace and clearing the clinkers off the bars and pushing them into a receptacle for removal. This is accomplished by resting the front of the fire-bars on the dead plate, the back bearer being a rotating cam-shaft with excentrics, on which is fitted each alternate bar, which has a slot fitting these excentric cams on their undersides. The other alternate bars are fixed to a bearer and in a recess on the front dead plate. On their upper edge another bar is fitted with a parallel ball-and-socket joint. The upper ends of these bars oscillate in a recess in the upper hearth plate. The fronts of the fire-bars also oscillate on the front dead plate, so that on the bearer shaft being rotated towards the front, the movable bars lift the clinkers and fuel forward off the fixed bars and a constantly clean fire is kept. At the same time new fuel is fed from the upper hearth plate. The shaft is rotated by a ratchet wheel worked by an excentric from a rotating shaft at the furnace front, driven by the forced draught blast engine. The air blast is brought from a conduit under the ashpits by pipes on either side and opposite each other, in the forepart of the ashpits. Special facilities are provided for clearing away the dust from the flues at all possible points, and a dust-settling flue or chamber is also provided between the furnaces and the chimney, which is preferably on the back of the furnaces.

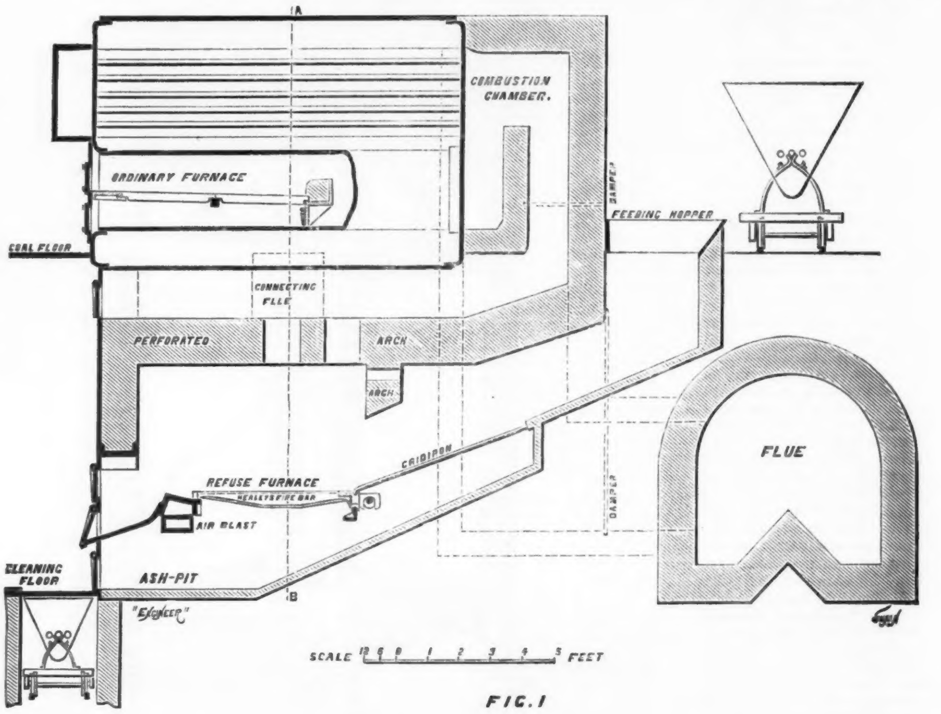


FIG. 1

Hitherto the practice as regards the generation of steam has been to place a tubulous steam boiler between the destructors and the chimney, leaving the walls of the flues to absorb a large quantity of the heat before reaching the boiler. Between the destructor and the boiler a Jones' fume cremator is frequently used, which consists of coke furnaces so constructed and arranged that the flues from the destructors conduct the gases over these fires by deflecting masonry, thus cremating them and rendering them innocuous by destroying the excess of moisture and effluvia which would otherwise escape as noxious vapour and condense in the atmosphere, and cause what has been recently described as an unmitigated nuisance.

At Cambridge, Messrs. Wood and Brodie's system of furnace is being adopted. It consists of a water-tube Babcock type steam generator placed in series between every two refuse furnaces. The waste gases are conducted through brick flues into a chamber under a V-shaped ash-tray or pit, and then over its upper edges through the fire-grate to the water-tubes and ordinary setting of the generators.

At Warrington a special refuse furnace has been erected in front of the furnace of a Babcock steam generator, the place of which it takes. It is fitted with forced draught, the refuse fuel being conducted by hoppers from the floor above to the furnace. The following are the results of working which Messrs. Babcock and Wilcox have kindly supplied.

*The Corporation of Warrington.*
*Test of Patent Destructor Furnace with Unscreened Refuse.*
*Warrington Installation.*

| | |
|---|---|
| Date noon to noon | Nov. 23 & 24, 1893. |
| Duration of trial | 24 hours. |
| Nature of fuel | Unscreened refuse. |
| Total quantity of fuel burned | 53,536 lb. |
| Quantity of fuel per hour | 2231 lb. |
| Total quantity of water evaporated | 61,314 lb. |
| Quantity of water per hour | 2556 lb. |
| Weight of clinker produced | 14,400 |
| Per cent. of clinker | 27 |
| Pressure of steam maintained | 66 lb. |
| Temperature of air in boiler-house | 45 deg. Fah. |
| Temperature of feed-water | 104 " |
| Temperature of gases leaving damper | 550 " |
| Quantity of water evaporated per lb. of house refuse | 1·14 lb. |
| Average temperature of copper wire test | 2000 deg. Fah. |
| Average air pressure (water) maintained | 8¼in. |
| Draught velocity in feet per minute | 82 ft. |

From the author's experience the system which recommends itself is that of placing a steam generator directly over the destructor furnace, so that the heat shall pass around or impinge directly on the heating surface of the generator. The ordinary generator furnaces are placed above the refuse furnace, and are used as supplementary furnaces to increase the temperature necessary for the higher pressure demanded, and also to cremate any obnoxious gases from the refuse furnace below. Where destructors are in use, and it is desired to utilise the heat from them to generate steam at high pressures, the generators may be arranged in a series adjoining the main flue to the chimney, and by connections the gases may be directed into their combustion chambers, and so utilised and cremated. Where it is practicable, however, to place the generators over the existing lower furnaces or destructors, it is greatly to be preferred, as being more effective.

There is no doubt that the gases from refuse are impregnated with a large percentage of moisture, and are of low temperature. This is shown by an analysis of the gases, where a preponderating amount of nitrogen is found, amounting to 22 per cent., and any contact with the side walls of brick flues has the effect of impairing the efficiency, the walls being always ready to absorb some of the moist heat, the surfaces necessarily having to be large. With these considerations it will be seen that to obtain the best effect the radiated heat must be absorbed directly by and transmitted to the generator. This is accomplished by placing a reverberatory perforated fire-brick arch over the refuse furnace, with the generator above it, so that when an excess of green fuel comes down from the hearth-plate, the regenerative heat from the arch assists to cremate the fumes before passing to the upper furnace.

There is no doubt that hand sorting of ashbin refuse will be largely discontinued on account of its degrading nature, and also from the decreasing prices of bones, rags, waste paper, &c., making it less profitable than formerly. There will therefore be a proportionately greater quantity of animal matter to be disposed of, and the consequent effluvia must be constantly dealt with, so that the need of an effectual fume cremator is absolutely necessary. These fumes it is proposed to cremate and destroy, with the assistance of the reverberatory arch, by the higher temperature of the combustion chambers of the ordinary and supplemental furnaces of the generators, this being their hottest part, the temperature of which will be never less than 1500 deg. Fah. It has been found that to effectually destroy refuse fumes, 1250 deg. Fah. is absolutely necessary, and it would appear almost impossible for any effluvia to escape after passing through these two heats. Means must also be provided for the admission of fresh oxygen into the combustion chambers if necessary to complete combustion, the gases or fumes from the destructors might also be burnt through the furnace bars of the supplementary furnaces if desired, when oil or producer gas is used as fuel.

The author has recently had some experience of the effect of escaping effluvia when saturated with moisture. It was proved in a recent law case that persons in close proximity to the 60ft. chimney shaft, from whence it was alleged the foul gases were escaping, scarcely complained, but numerous complaints arose from those from 300 to 1000 yards distant, showing that it took that distance to bring the saturated effluvia to earth. In some existing plants in which no utilisation is attempted, the cost of fuel for the crematory fires has been so great that they have been discontinued, but serious complaints from the neighbourhoods are now arising, thus showing the advantages of cremation.

The calorific value of refuse being low, it is necessary to provide ordinary generator furnaces to assist in raising the steam to the required pressure, for economical use as well as for cremating, as in several of the existing plants with the boilers in the flues, 40 lb. pressure per square inch is all that can be obtained, and at Warrington, as previously stated, 66 lb. only is obtained even with forced draught. In the ordinary furnaces of the generator, good fuel should be used, and if a supply of Russian oil can be obtained, that, or producer gas, appears to be especially applicable.

Having now described the general principles of the generation and absorption of the heat by the generator, and having specially in view the use of the steam generated by it for electric light stations, viz., to assimilate the supply to the demand, the author will deal with the question from the latter point of view. It is well known that the demand of electricity during the day is so light, even where a fairly high load factor is obtained, that the use of the steam generating plant at even half its capacity would be an excess, so that a system of heat storage is necessary for the economical use of the refuse, as the destructors must always be at work. Any ordinary form of steam generator may be adopted, but the cylindrical dry back marine boiler with two flues, or the inclined water-tube boiler of the Babcock and Wilcox type, are best suited. They are illustrated at Figs. 1, 2, and 3, and they are so well known as to need no further description. Fig. 2 is a section showing the method of connecting the refuse furnaces to either steam generator. Lancashire boilers on account of their length are not well suited to the present purpose, as the temperature of the gases in the combustion chambers frequently falls below 1250 Fah., and allows the moisture to pass away undecomposed. In all cases the refuse gases are conducted into the combustion chambers or their hottest part, while in the marine form they

---

[*] Paper read on the 1st October and open for discussion on the 5th inst.

are led to the space above the flues and opposite the tubes, the gases from the ordinary and crematory furnaces of higher temperature mixing with them. In the water-tube generators they enter the ordinary furnace from behind the furnace back, in both cases meeting with the partly incandescent fire-brick masonry, which assists in evaporating any moisture and destroying the effluvia. It is also necessary to keep the generators short, otherwise the feeding floors must be placed over the boilers with descending hoppers. This design also takes up more ground area for the inclined roadway, the other forms being conspicuous for the small space occupied by them.

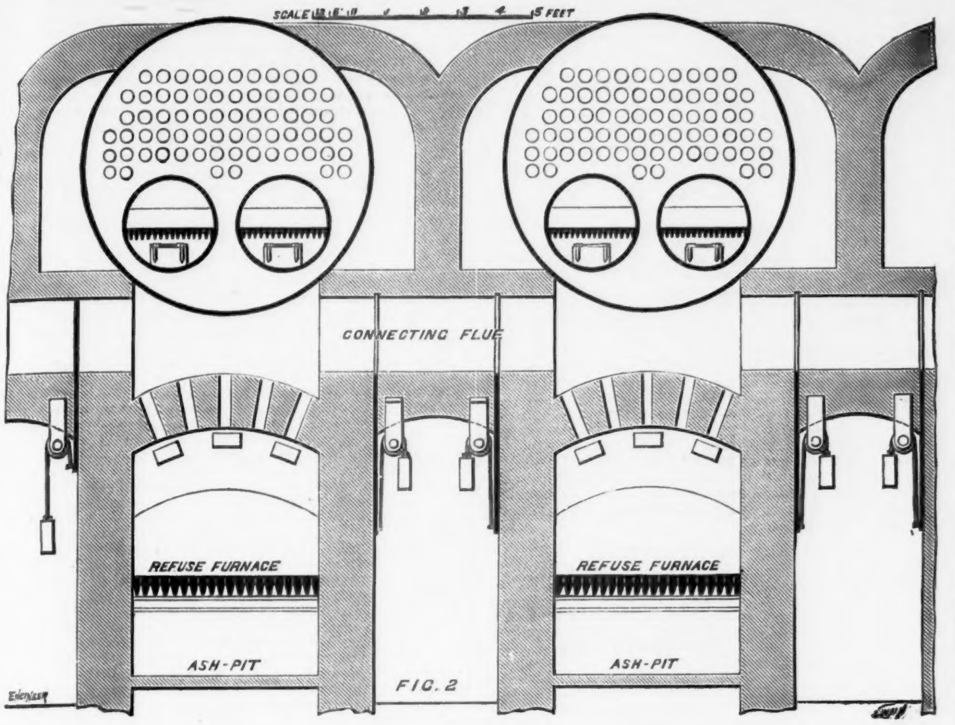

FIG. 2

Referring to the refuse destructor and steam generator combined, for dealing with 420 tons of refuse per week—which is an average quantity from several London vestries—some six or eight sets would be required for electric lighting purposes. These would be in one battery, adjoining each other, the flues between the arches over the refuse furnaces, and under the generators, would communicate with each other, so that any number of refuse furnaces might be coupled to one generator and its crematory furnace. For the day load, however, they should be worked in sets of three, so that the middle generator alone would have its ordinary furnace in use, the refuse furnaces below all communicating with the one generator by dampers being opened between them, and other dampers closing the two outer generators from the chimney flue. It will thus be seen that the two outer generators would be kept at the same working pressure as the middle one, and would always be available by their own furnaces being brought into use, so that the stand-by losses would be wholly taken up by the refuse. There would also be an excess of steam, during the extreme light loads, which should be stored in the following manner:—

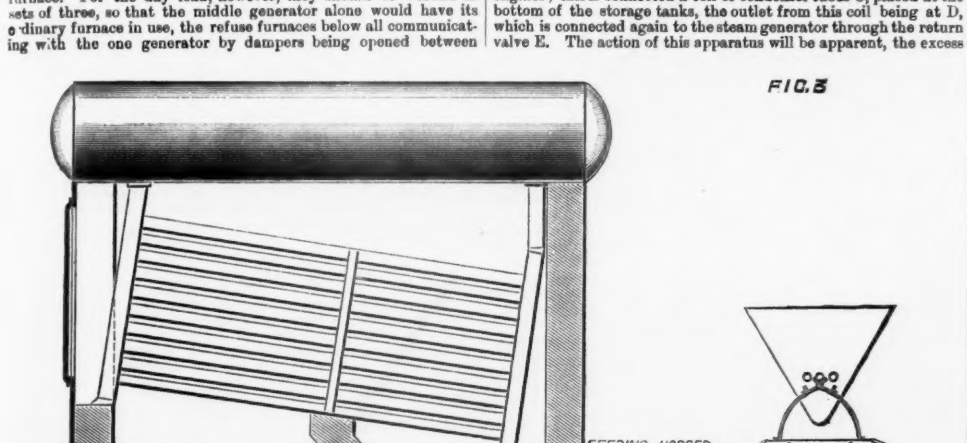

FIG. 3

A tank or reservoir properly clothed to prevent radiation is to be placed as a roof to the boiler house, and in this tank near the bottom is fitted a coil of pipes. The waste steam would be taken into this coil which is immersed in water, thus condensing the steam, and ejecting the condensed water into the tank itself, eventually filling it with practically distilled hot water every day, and this would be the case either with condensing or non-condensing engines; but when condensing engines are used it will be preferable to filter the condensed water from the air pumps, and use this as feed-water through the boilers, and thence into the storage tanks, as before described, but where non-condensing engines are used it would be better to allow the exhaust steam in the coil to heat up and boil the water in the storage tanks, in which would be deposited most of the impurities, the coil being connected by a system of steam flow and water return to the generators. Under these circumstances a live steam feed-water heater and separator would be necessary to feed the generators during the light load, bringing into use the boiled storage water during the heavy demand for steam.

This may be explained by reference to the diagram, Fig. 4, showing the steam generator and heat storage tank and their connections. A is the steam main supply pipe connecting the generators with the engines, &c., from the main by means of an automatic balanced steam valve B, allowing the escape of any excess steam over that required for the immediate requirements of the engines; this is connected a coil of condenser tubes C, placed at the bottom of the storage tanks, the outlet from this coil being at D, which is connected again to the steam generator through the return valve E. The action of this apparatus will be apparent, the excess of waste steam being conducted through the coil, which is immersed in the water in the tank—if used with a non-condensing plant—containing the original impurities inherent from its source; thus steam heat will then be transferred to the volume of water as previously stated of 20,000 gallons, preferably in four tanks or reservoirs, the condensed water returning by the pipes and valve E to the generator. Where carbonate and sulphate of lime is present in the feed-water, and with a non-condensing plant, it will be precipitated in the storage tanks, the live steam feed-water heating up the water to 300 deg. Fah., setting up the separation on its entering the tank and afterwards settling in it, means being provided for preventing its settling on the coil, so that practically pure hot-water will be provided for use without any pumping under pressure. In condensing plants, the feed-water having been filtered in coming from the air pump, it may be condensed and ejected into the storage tanks through the generators, having been previously purified, or directly into the tanks, and there reheated as in non-condensing plants. It must also be observed that any generators not actually in use for the day load will also be additional storage reservoirs.

When multitubular generators are used, care must be taken that increased internal tube area is afforded for the passing of the gases from the three refuse and crematory furnaces. This system can be applied to existing destructors, as water-tube generators may be made of a width to suit such circumstances, where probably cylindrical boilers could not be so placed. The net result of this system would probably be, that ¾ lb. of water would be evaporated by 1 lb. of refuse, allowing for the lesser value of street sweepings or sludge, and the absorption of a certain quantity of heat in the furnace masonry, as compared with the 1 lb. of water per 1 lb. of refuse, which has actually been accomplished—as before explained—a result which is corroborated by Mr. A. Collins, A.M.I.C.E., of Reading, and the Warrington tests in directly-fired generators. Reducing this to financial terms, the saving in barging which has been mentioned as the only credit must be first considered. This, according to the average cost per ton to several of the London vestries, amounts to 3s. per ton after collection, and 70 per cent. can be utilised, leaving only 30 per cent. of ash and clinkers as a residue to be disposed of, which in the spring is readily marketable for road-making, and where crushing machinery is in use it can be prepared for mortar, and with cement manufactured into street paving. This source of profit will, however, be absorbed by the cartage on the unsold residue, also by the fuel account for the generator furnaces, for working the forced draught and moving the furnace bars, the net saving being therefore the cost of barging or disposal of 70 per cent. at 3s. per ton; and, taking six furnaces burning ten tons each every twenty-four hours, equal to the consumption of 420 tons per week of seven days—294 tons at 3s., will represent the saving in barging, amounting to £44 per week, or £2288 per annum.

The gross credit will be the value of the steam generated from the refuse. As each furnace will be of a capacity to burn ten tons every twenty-four hours, and taking 20 lb. of steam per indicated horse-power per hour, and non-condensing engines without the cremating fires, the effective evaporation will be equal to 35 indidated horse-power per hour per generator set and available for electric lighting. From the returns of the various London electric lighting plants, published in *Lighting*, 1d. per unit appears to be a fair average for the cost of coal. Six destructors and generators would give an hourly output of 210 indicated horse-power from refuse only, or allowing 15 per cent. for frictional loss = 177 electrical horse-power, which at 1·34 horse-power per unit = 128 units at 1d., or 11s. 1d. per hour, say £93 1s. 6d. per week, against which the extra cost of maintenance, wear and tear have to be debited. If ashbin refuse alone were burnt the results would be 15 per cent. to 20 per cent. in excess of this, but this result could only be attained if the steam were used by the engine as generated, but against this, and as a general debit, the inherent losses of storing the heat and the reheating will have to be considered. As this process will be going on for two-thirds of each twenty-four hours, the author estimates this loss at 30 per cent., but being sixteen hours only out of the twenty-four = 20 per cent. on the total 35 indicated horse-power, leaving a net effective result—after deducting 15 per cent. for frictional losses—of 23·6 electrical horse-power per hour per set, which may be absolutely depended upon. The total value at 1·34-horse power per unit equals 1s. 5½d. per hour per set, or 8s. 9d. per hour for the six sets; that is £73 10s. per week, or, per annum, £3822; less £350 for steam for auxiliary blast and grate engines and pumps, £350; total, £3472.

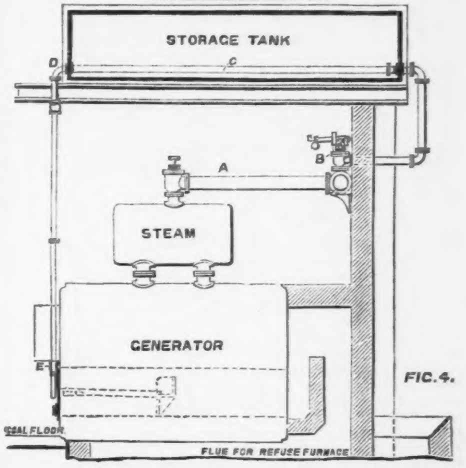

FIG. 4.

Mr. G. Watson, C.E., of Leeds, in his paper read before the British Association in 1892, gives the theoretical value of ashbin refuse as 1 lb. evaporating 2·13 lb. of water and the practical result at 1d. per indicated horse-power per hour with a steam generating plant of improved type, or 1s. 3d. per cell per hour, burning 5 cwt. of refuse at a total cost of 1s. 10d. per ton. At Oldham, some authorities give the cost at 1s. 6d. per ton, including all expenses and depreciation. Taking these figures and the evaporative tests of the author, of Mr. Collins, and those from Warrington, the foregoing figures may be considered fairly substantiated, together with the results deducible therefrom. The ordinary or supplementary furnace heat is not considered in these estimates, as that would be directly available for extra evaporation at proportionately increased returns. The author considers, as previously stated, that a plant capable of dealing with 420 tons of refuse per week would be of suitable working capacity for a London vestry. The plant would consist of eight refuse furnaces—two in reserve—with six steam generators for 140 lb. working pressure with feeding, coal and cleaning floors, forced draught, machinery, movable fire-bars, storage tanks and chimney, and capable of a total output of 900 brake or electrical horse-power when fully loaded. The author estimates the cost, including £3000 for the site, at £18,000.

The maximum indicated horse-power from the refuse only is computed at 48-H.P. per cell, the extra evaporation by the supplementary furnaces at high load utilising the remainder of the heated feed-water out of a total of 25,000 gallons. The following is a statement of the returns, which are inclusive of engineers' charges and royalties.

The quality of ashbin refuse varies greatly. During the summer it is generally very poor, but from the better districts of London it may be advisable to sift it over a shoot during early spring, reserving the better fuel, which it will be found to contain, for use in the ordinary furnaces during the summer, and thus increasing the economy. From inquiries the author finds that the refuse from some localities would not repay this necessary outlay. The author's experience is that the Paddington siftings have been fully 25 per cent. less in value in July than in March, which has caused a lower evaporative average value to be given than the individual tests before referred to by others, as on individual weeks in January to March the breeze was particularly good, which is shown by the water and quantity tests.

The author has endeavoured to place the complex question of the disposal of town refuse in a practical light before the Society. The obtaining of the facts has been the outcome of the necessity of obtaining a cheap fuel for slow steaming, and of utilising refuse for producing electricity. The author's experience in connection with electric lighting since 1878, particularly when required for factories, is that would-be users first ask themselves—"Have I engine or boiler power to spare?" The idea of a separate plant using a waste product has been, until the past few years, quite foreign to the question. It now, however, may be said to solve an important problem. It will probably be admitted from what has been stated, that in addition to meeting sanitary and hygienic requirements, this system of refuse utilisation constitutes a valuable source of profit, to which public authorities are at length becoming alive.

## A SHIPYARD FOREMAN ON TRADES UNIONS AND LABOUR TROUBLES.

The Clyde Foreman Shipbuilders' Mutual Association met at Duncan's Hotel, Glasgow, on the evening of the 27th October, to discuss the paper read on the 28th April last upon "Trades Unionism," by Mr. Hugh Glen, of Clydesbank, which was reported at the time in The Engineer.

In the course of an interesting discussion, in which many of the members took a part, Mr. J. F. Paton, head foreman fitter at Messrs. W. Denny and Bros.' shipyard, Dumbarton, after complimenting Mr. Glen upon his able paper, said:—

The writer of the paper, in referring to Trades Unions in their in newest form, said:—"There is no subject in all the range of social or political economics that appeals so loudly to our consideration." I believe we may add "Amen" to that sentence, because industrial wars have been going on with increasing vigour before and since Mr. Glen's paper was written, and we can safely say, had it not been for the wretched blundering of our Legislature while tinkering with the conspiracy, combination, protection of property, and the picketting laws, for reasons best known to themselves, not 5 per cent. of the numerous strikes would have taken place, or continued for any length of time. Mr. Glen speaks of "colossal fortunes made in a brief space of time by successful masters, making many anxious for a share of the gains." There is nothing strange about that, but he must have heard of colossal losses too—what then. Not a word! Although we are "buffers" in a sense between capital and labour, we are not met to consider whether one or the other should dictate terms. Mr. Glen, while referring to the rights of both, steers clear of the point. But I hold, it is our duty, and also our right as a perfectly neutral body, to watch carefully the progress of every disturbing element introduced, and do what we can to preserve a good relationship between both; and yet it is sad for us to think that at this time of day we find members of trades councils, and workmen, or labour representatives openly bullying city and local authorities who are responsible for law and order. Mr. Glen says, "Workmen have united, and in all fairness we see no reason why they should not unite to guard their own interests and consider their value as well as our doctors or lawyers." "Why should not our workmen have as good a right to their union as our masters to their association, &c. &c.?" Mr. Glen is too late in the day in bringing up this point. It has been settled long ago; but the point which concerns us is just this: Should labour have the power to domineer over capital or capital over labour? Both are supposed to have equal rights. Doctors or lawyers have no Act of Parliament at their back to poison or plunder when they please or how they please, but we can almost believe from recent events that the men's leaders have the power to do both with impunity. We seldom read one of their orations but it is a case of poisoning the minds of all within reach of their voice; and when a midnight excursion has been arranged in the interest of labour, "urgent business" necessitates the departure of certain local justices to the coast. I cannot understand why men should be allowed to roam at large about a town or country like a lot of wild beasts, destroying property and frightening the life out of people, because employers will not knuckle down to their demands. I hold that all this nonsense must stop, and the fruits of both capital and labour be preserved and protected at the point of the bayonet, if need be. The administration of justice in our courts is simply a farce, justices and counsel alike being saturated with political bias and under the thumb of the mob. In following Mr. Glen through his interesting paper, we have evidence of great care in selecting reliable information for us. I have, like him, looked into the costs of trades unions, their benefits, and their errors; but their future seems to me to be something black and ugly, unless the reins of supervision and government are pulled in a little tighter. Mr. Glen, in the last page, says:—"Masters will associate and federate more and more, and men will unite and amalgamate more and more, and the sooner the better." Why? If the law of the land is not strong or good enough to keep both right, then the sooner our Legislature takes the question up the better for all concerned. Then Mr. Glen goes on to say, "My hope of fair and equitable adjustment of terms lies in the fact of each knowing the power and endurance of their opponent." No, no, Mr. Glen; this is an industrial question, and should not be allowed to approach the "beggar-my-neighbour policy." But to get over the bridge between us—Will this suit him, gentlemen? (1) Employers and workmen have a perfect right to unite, amalgamate, or federate; but neither should have power to put the ordinary laws of a civilised community at defiance to forward their own interests. (2) Employers and workmen have a perfect right to make or refuse a demand; but neither should have the right or the power to prevent a third party from accepting the conditions laid down; or, to put it another way, merchants or employers have the right to charge what they please for their goods or manufactures. Workmen have also the right to put on any value they please on their labour; but can you imagine any reason why the one should be favoured by the State and not the other? The words federation, or to federate, have been grossly abused in labour circles. We are told openly by trades and labour unionists that federated bodies aim at, and will have the power to stop the necessaries of life going into any district when capital and labour is at variance, in order to force capital to give way to the demands of labour. The public are told through the press what the 20th rule of the Miners' Federation of Great Britain is, and Mr. C. Robertson tells us through the same source, "That when the Englishmen saw the Scotch miners nine weeks' on strike, they should have applied the rule and stopped coal coming into this country." We know that strikers break away from their leaders and create mischief, but is there any reason why our Government cannot step in and stamp out such combinations before it is too late? I have no manner of faith in conciliation as a balancing power between capital and labour. Councillor Ben Dean—miner's agent—is reported to have said lately at a meeting of workmen:—"he was not in favour of strikes," he "believed in conciliation; but they would get nothing by it, unless prepared to hit hard, if hard hitting were required." Just so, employers, on the other hand, believe in conciliation too; but, at same time, don't hesitate about hitting hard when necessary. Workshops are shut up, capital is also shut up. Natural result, the general public have to bear the brunt of it, and who is to blame? You would have noticed lately during the industrial troubles the many frantic appeals for some third party to step in and end the disputes, but one and all sweetly declined. I see nothing for it but to allow capital and labour to fight if they wish to do so, but our Legislature should have the power to hedge both in, in such a way that no one outside of the ring would suffer. Workmen must not be allowed to prevent others from doing what they want to do. Employers must not be allowed to prevent other employers taking in hand contracts or work they have refused to do. I notice also that Mr. Glen, while covering little more than a page of his pamphlet with the benefits of Trades Unions, omits nearly altogether the fact that remedial measures are urgently wanted to cover the numerous errors and evils pointed out by him, and then he quietly begins the last part of his paper on the future of Trades Unions by saying: "I can give no forecast with certainty." I have, perhaps, said enough on Mr. Glen's paper; I may add, it seems to me the electors, rich and poor alike, do not seem to realise their power for good or evil when entering the ballot box. Modern faddism apparently has more concern for them than bread or butter, and I have no manner of sympathy with them when called upon to pay the enormous expense for extra police or troops when required in a district to preserve law and order through labour troubles. We have far too many political weeds in power to begin with, and the remedy for this evil also lies with our Legislature. Every individual ratepaper, in my opinion, should pay an equal share of the expense, without regard to either income or rent value; and I am certain the worries and troubles between capital and labour while at close quarters would be reduced to a minimum.

In the remainder of the discussion Mr. Lambie—Greenock—said he was in favour of paying workmen by results; and that the opinions of the older and more experienced men should prevail in the settlement of disputes.

Mr. Haughie—Govan—said he was opposed to the levelling of workmen, without regard to skill, which trades unionism effected. In his opinion workmen should be divided into three classes.

Mr. Cooper—Port-Glasgow—contended that all in charge of labour should combine, if for nothing else than the prevention, as far as possible, of friction between capital and labour.

Mr. Glen, in replying, said he still believed in trade regulation of wages, as employers had more than once broken faith with men; but he was against time wages pure and simple, and thought all workers, either time or piece, should be paid according to results. He belived in conciliation.

## SHELLS CAPPED WITH WROUGHT IRON.

It is extremely doubtful if the Ordnance Department of the Navy will conduct further experiments with shells capped with soft wrought iron. The first experiments, which were held on October 5th, at the Indian Head Proving Grounds, resulted so seriously to the gun that the Ordnance Department officials have come to the conclusion that further trials in this direction would be dangerous. The shells tested were four experimental Wheeler-Sterling 6in. A. P. shell, and the plate used was the 6in. Harveyised nickel-steel barbette plate, A-883, Carnegie Steel Company, which had already been attacked by four 6in. A. P. shells. Before the capped shell was fired, two projectiles were discharged against the plate, the first soft to file on surface all over, relative low carbon and high chrome, and the second hard to file as far as lower edge of bourrelet, ogive magnetised. The third round, in which the capped shell was used, resulted as follows, according to the official report of Ensign Tisdale, who superintended the test:—"Projectile, Wheeler-Sterling 6in. special A. P. shell, No. 6, of normal dimensions and weight, hard to file to ¾in. below the bourrelet, ogive magnetised, of relatively high carbon and low chrome. An annular ring ½in. wide and ⅜in. deep at its forward end was cut in the ogive about 3in. from the point. A soft wrought iron conical cap ½in. thick was placed over the point of the shell's ogive, fitting it neatly, and was held partially by the magnetism, but principally by three screws equidistant, about 1½in. from the bottom end of the cap, the inner ends taking in the groove, and setting up evenly against the shell. The cap then presented a length of about 3½in. When put on, it seemed to be perfectly tight and rigid. Weight of cap, 8 lb.; charge, 43·8 lb. O. P.-b.; striking velocity, 2000 foot-seconds; striking energy, 2776 foot-tons. It was my opinion that 2100 foot-seconds would be necessary to perforate the plate; but as this velocity was required to perforate 6in. Harvey plate without a cap, 2000 foot-seconds was used to demonstrate the value of the cap. The shell struck the plate 20in. from its top, and 48in. from its left edge; angle of impact inclined 6 deg. to the normal, striking the plate 12in. to the left of the point desired, which would have given a normal impact, smashed up the ogive welding in the plate, apex of cavity ·9in. in from the face of the plate, estimated penetration from 3in. to 4in. The remainder of the shell broke into numerous fragments, but the greater part was in two longitudinal fragments 7in. long, forming the lower body and base, weight 44 lb., its edges being fuzed, and showing a tough metal. A back bulge 2½in. high, about 18in. in diameter and cracked through, was raised. The plate about the impact scaled considerably, mostly in a vertical direction, the hardened surface separating from the softer metal of the plate, as before. A few surface cracks were started. No trace of the cap was found. At the time, the deviation of the shell from the line of fire was attributed to the peculiar form of the cap." After giving the results of another round, fired with a projectile, hard to file ¾in. below the bourrelet, which, with a velocity of 2100 foot-seconds, perforated the plate, the report concludes:—"None of the above shell did any more work on the plate than the ordinary service A. P. shell, and they broke up in very much the same manner. The plate itself acted remarkably well. (See photograph No. 320, showing the fragments of all the above four shells, partially built up) After the firing was over, the fragments of the different shells were more minutely examined, when it was found that there were marks of rifling on the lower body and rear of shell No. 6—third round—which had the soft wrought iron cap on it. The bore of the gun was then thoroughly cleaned out, wiped and examined. It was found that at a point about 8ft. 6in. from the muzzle, the gun was very seriously injured, the shell having jammed in the bore, possibly by reason of the cap being jarred off on discharge, the shell passing through it, or being jammed by it. This injury is the subject of a special report. The action of the shell in the gun, then, explains the great deviation from the mark on the plate in round No. 3."—*United States Army and Navy Journal.*

Another new submarine boat is announced. A Reuter's telegram from Melbourne says that Mr. Seymour Allan, a resident of Sydney, has invented a submarine torpedo boat capable of sinking to any depth and of travelling under water as quickly as on the surface without revealing its presence. A working model of the boat was tried the other day in the public baths at Melbourne in the presence of the Earl of Hopetoun, the Governor, the Naval Commandant, and a number of naval and military officers. The experiments were a complete success, the model rising or sinking, turning, reversing, or remaining stationary in obedience to the electric current by which it is worked. The inventor claims that a full-sized boat would be capable of remaining under water for three days and would carry torpedoes on the bow and stern decks. When fired the projectiles would be magnetically attracted to the bottom of an enemy's ship. The Admiral commanding on the station, who inspected the model at Sydney, declared that if the vessel would do what the model performed it would revolutionise naval warfare.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

Iron trade prices this week show little change from the quotationt given last week, but surprise has been occasioned by the statemen that in the ironmaking districts of the Western States of America bar iron at the present time is being rolled at £4 12s. per ton, and delivered to consumers 1000 miles or more inland from the Atlantic coast at £5 6s. per ton. This figure is compared to £6 5s., at which Staffordshire common or ordinary bars are being delivered to consumers in the West and other parts of England. Statements like this, showing the low prices now ruling in the American iron trade, are on a par with the report lately made to the Middlesbrough Chamber of Commerce by Mr. Jeremiah Head, that pig iron is being made in Alabama at 24s. 2d. per ton, and sold at from 26s. to 29s. per ton in trucks at works.

An important event of the past week has been the practical starting of the new steel works at Brierley Hill, erected at a cost of about £40,000 by the Earl Dudley Round Oak Iron and Steel Works Co. The works are not yet fully completed, and a meeting of the shareholders and others interested is called to consider the question of the raising of additional capital, but the company is now in a position to supply open-hearth steel in the form of bars, engineering sections, &c., for which there is an increasing demand. The restart is also announced this week of the Congreaves blast furnaces, late the property of the New British Iron Company, by the new proprietary.

Authoritative information this week of the extent of the orders for bridge and girder work lately placed in this district on account of the new Manchester, Sheffield, and London Railway extension puts the amount down at 8000 tons, and not at several exaggerated figures greatly in excess of this, which have appeared in different quarters. As previously announced, the work has gone to the Horseley Engineering Company, Tipton, and delivery is to extend over two years. The entire bridge work required for the line is understood to have been divided amongst seven British engineering firms located in various parts of the kingdom. As regards the Horseley Company's contract, all the material employed is to be of steel, and it is eminently satisfactory that the Staffordshire Steel and Ingot Iron Company has taken the order for the metal. The Horseley Company is at present employing some 600 workpeople.

In the matter of the brickwork necessary to the extension, this district has benefited to a greater extent than as concerning the iron and steel work. For the tunnelling required on three or four out of the seven sections the whole of the orders have come here. West Bromwich is the town which has secured the business, a number of firms having shared the contracts. One firm alone—Messrs. P. and S. Wood—will supply 10,000,000 blue and brindled bricks, and other firms have been equally fortunate. Large orders for bricks and invert blocks and copings have also just been booked by Messrs. Wood and Ivery for the Birmingham water scheme, through the Glasgow contractors for the work. These orders coming just in the face of winter, and after the prolonged depression in the iron trade, are all the more welcome. Delivery will be spread over a period of three and a-half years South Staffordshire stands pre-eminent in the production of blue bricks for constructive engineering purposes. For tunnel work, sea walls, quays, culverts, reservoirs, and all works where great strength is required, the bricks of this district is, it is stated, deemed by competent engineers to be even more substantial than granite. The Severn tunnel is, it is noteworthy, constructed of Staffordshire blue and brindled bricks.

The experience of gas engineers in the Midlands of late has been somewhat trying. The Gas Committee of the Birmingham Corporation are now paying for coal between £75,000 and £80,000 a year more than they paid a few years since, yet the price of gas remains the same. Then the introduction of the eight hours' shift for the men has also cost the Corporation a serious sum of money. Notwithstanding all this, the committee hope to reduce the price of gas in December, and they have also given immediate satisfaction to the manufacturers of Birmingham and district by lowering the price of gas-coke on Thursday, November 1st.

The new method for the treatment by electric chemistry of the materials used in the North Staffordshire pottery trades, to which I referred a few weeks ago, and which it is alleged is destined to supersede the ponderous machinery at present used in these trades for the grinding and preparing of the potting materials, is still engaging attention. It is stated that the results so far obtained have prompted several scientific gentlemen and capitalists to formulate an arrangement for the erection of an initial plant on a practical working scale. I hear that they do not expect to at once arrive at a complete solution of the problem, but they apparently believe in its possibility, and intend to go on with it. Meanwhile expectation in the pottery trade runs high as to what the exact particulars of the new process may be, and caution is countenanced in the expenditure of more money upon existing plants, as in case of the success of the new system such machinery expenditure would be lost. The present position of the potteries industries, owing to prolonged bad trade, growing foreign competition, and other causes, invests any suggestion for increased economy in processes with marked importance just now.

Well known in mining engineering circles the kingdom through as one of the least fiery and best equipped—even as it is one of the most prolific—coal raising concerns in England, the Sandwell Park Colliery, of West Bromwich, has hitherto been singularly free from accidents of a serious character. This enviable record, however, has been broken, for about seven o'clock last Saturday morning an explosion of fire-damp took place, which injured thirteen miners, of whom two have since died. The men were working in No. 2 stall of No. 1 pit, about a quarter of a mile from the bottom of the shaft. The usual first examination of the pit had been made, and "all safe" had been reported. The under-manager was making a second examination of this stall when a sudden rush of gas was heard, and this was followed by an explosion. The men were working with naked lights. It has been customary to use them, as that part of the pit was considered very safe. One theory of the explosion is that a hollow place had been struck, and that there had been also a change in the pressure of the atmosphere since the first examination. The inquest was opened on Wednesday, and adjourned until the 22nd instant for scientific evidence to be adduced.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The reports as to the condition of trade in connection with the iron and engineering industries of this district vary considerably. In some quarters one hears that there is apparently a "turn for the better," and that more business has been done in the iron market during the past week. Engineering establishments also are here and there reported to have experienced an improvement, and that they are better off for orders than was the case a short time back. There is, however, still no general improvement in the position, and business in the iron trade, taking it all through, continues extremely slow, with prices weakening, if anything; whilst as regards the engineering industries it is, as I have reported for some time past, only in exceptional cases where establishments are either better off for orders or more than very moderately engaged, and the outlook shows no reliable indication as yet of any revival as regards either the iron or engineering industries of Lancashire.

There was a more numerous attendance on the Manchester Iron Exchange on Tuesday than for several weeks past, and here and there an increased weight of business was reported. Generally, however, there seems to be an absence of inquiries of any moment, and where business was being put through sellers for the most part had to give way upon recent quotations. Lancashire makers of pig iron still quote on the basis of about 39s. 6d. for forge to 42s. for foundry, less 2½, at the works, but these are little more than nominal figures, so far as business doing in this immediate district is concerned, and transactions in local brands are chiefly confined to occasional special sales, or where makers have exceptionally favourable rates of carriage. District brands continue to ease down gradually, and in Lincolnshire forge moderate transactions have been put through at 38s. 6d. net cash, delivered equal to Manchester, with consumers who have further orders to place holding out for a still lower figure; but fair transactions would in all probability be put through if makers were prepared to accept about 38s. net cash, delivered here. Foundry Lincolnshire remains fairly steady, quotations averaging 40s. to 40s. 6d. net cash, but Derbyshire brands continue weak and irregular, ranging from 43s. 6d. and 44s. up to 45s. 6d. and 46s. net cash, delivered Manchester.

With regard to outside brands offering here, Middlesbrough remains without any really quotable change, 44s. 4d. net cash being still about the minimum for good foundry qualities, delivered equal to Manchester, with makers asking 6d. above this for special named brands. Scotch iron is, however, gradually giving way as the production increases, and 47s. 6d. net prompt cash is now the full quoted price for Eglinton delivered at the Lancashire ports, with sellers in the open market disposed to come something below this figure. and Glengarnock offered very low.

In the manufactured iron trade business continues of a hand-to-mouth character, with forges not kept running more than four to five days per week. Makers still quote late rates, but here and there give way to secure business. Delivered in the Manchester district, quotations for Lancashire and North Staffordshire bars remain at £5 7s. 6d. to £5 10s., but 1s. 3d. per ton under these figures has been taken. Lancashire and Staffordshire sheets are still quoted from £7 to £7 5s., and Lancashire hoops £5 17s. 6d. for random up to £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

The position in the steel trade remains without improvement, and only a very limited business is reported in either raw or manufactured material. For ordinary foundry hematites prices now average about 52s. to 52s. 6d., less 2½; ordinary basic billets remain at about £4 net cash; steel bars are quoted £6 to £6 2s. 6d.; and for steel boiler plates makers are asking £6 to £6 5s., delivered in the Manchester district, but business is scarcely practicable at this figure.

In the metal market buyers still give out only the smallest possible orders for manufactured goods, in the expectation that list rates, which are still maintained at the last advance, will have to give way.

The opening paper on Saturday last, for the discussion session of the Manchester Association of Engineers, was one by Mr. John Holliday, A.M.I.C.E., on the cost of steam raising, in which he dealt with his subject under four heads, viz.: Fuel, working expenses, maintenance, including insurance, and capital charges, and gave calculations showing the cost of evaporating 1000 gallons of water, which he adopted as a convenient number, at a brewery with which he was connected. In summarising the cost per week per 1000 gallons evaporated, of the steam made with forced draught and natural draught boilers respectively, Mr. Holliday said the average amount evaporated per week was 113,560 gallons by forced draught, and 195,440 by natural draught boilers, the larger amount evaporated by the latter giving it a slight advantage over the forced draught, but that in the latter system the fuel bill was 2s. less per 1000 gallons evaporated, and the total cost in the forced draught was only 7s. 8d., as compared with 8s. 6d. per thousand gallons in the natural draught. In considering the cost of steam raising it should, however, be remembered that the solid was not the only form in which fuel could be used. Gaseous firing with water-gas, affording as it did opportunities for recovering valuable waste products, such as sulphate of ammonia, had already been tried in several places, and it would be interesting to know what would be the minimum demand for steam that would justify a manufacturer in putting down a water-gas plant, complete with apparatus for the recovery of sulphate of ammonia, and firing his boilers with the water-gas made. In the course of discussion on the paper, Mr. James Hartley remarked, with regard to mechanical stokers, that he knew a case where a very considerable saving had been effected by discontinuing their use. Mr. J. Nasmith gave particulars of the cost of steam raising in several Oldham mills, which showed a range of from £3 2s. 5d. up to £5 14s. per thousand spindles. With regard to inferior fuel, he thought its use ought to spread, provided that the furnaces were specially adapted for it, and the boiler was fitted with appliances for dealing with it effectually. As to gaseous fuel, he had found that the gas produced almost invariably passed through the fewer burners when the many were not open, so that the system was not economical. The use of this fuel was only economical when adopted for steam raising in combination with other purposes. Mr. Marshall said he had adopted forced draught boilers, and not only got more power than previously, but saved a considerable sum in the cost of fuel. Mr. Craven pointed out that gaseous fuel possessed many advantages in its application for blast furnaces, and in many other cases, but not for burning under the flues of a steam boiler. Mr. Meldrum gave some interesting details as to the use of waste products for steam-raising purposes in connection with ironworks, collieries, &c., by which 75 per cent. was frequently saved. In one case the economy amounted to thousands of pounds a year, and he might add that the calorific value of inferior fuel was often as great as that of dearer fuel.

The outlook in the coal trade continues anything but satisfactory, and the winter season has so far brought forward no appreciable improvement in prices, such as is usually looked for, at any rate in the better qualities of round coals, suitable for housefire purposes. These still meet with only a moderate demand, and it is exceptional where the pits are able to work full time, four to five days per week remaining about the average. The most that can be said is that the better qualities of round coal are maintaining late rates, but it is still exceptional where more than 11s. is being got for best Wigan Arley, whilst Pemberton 4ft. and seconds Arley can be bought for 9s. 6d. to 10s., and common house coals 8s. to 8s. 6d. at the pit mouth. With regard to the lower descriptions of round coal, trades continue in an extremely depressed condition, with the probability of even still lower prices in some of the inferior qualities. Common round coals still move off very slowly for iron making, steam and general manufacturing purposes, and with plentiful supplies upon the market excessively low prices have to be taken, 7s. being about the average figure at the pit mouth, only specially good sorts fetching more than this; whilst engine fuel is a complete glut upon the market, with so many special parcels offering at excessively low figures, that prices generally are weakened, and common low slack is readily obtainable at 3s. to 3s. 6d., with better sorts averaging 5s. and 5s. 6d. per ton at the pit mouth. In the shipping trade only a quiet business is reported, with common round coals offering for steam purposes at as low as 8s. to 8s. 6d., and better descriptions, suitable for house fire consumption, fetching about 9s. to 9s. 3d. per ton, delivered at the Garston Docks or the High-level, Liverpool.

*Barrow.*—There is no change to note in the hematite trade this week. Orders are scarce, and only thirty-three furnaces are kept employed. Stocks have decreased only ten tons, and now represent in warrant stores 158,500 tons. Prices are easy at 43s. 6d. net cash sellers, 43s. 5d. buyers. Makers are quoting 44s. to 45s. 6d. for mixed Bessemer numbers, net f.o.b. Makers are holding considerable stock.

Iron ore is weak at 8s. 6d. to 13s. 6d. from ordinary to best samples, net at mines.

Steel makers are only indifferently employed in most of the heavy departments, except that of steel plates. Rails are quiet.

Shipbuilders are busily employed, and report the prospect of new orders.

Coal and coke quiet at late rates.

Shipping very depressed, although the returns show an improvement on the corresponding week of last year.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE South Yorkshire coal trade is not so active as it was last week. One or two reports confirm this statement, although others say the opposite. On the whole, however, I am inclined to believe that trade is rather more depressed than it was a week ago. The pits are at present working five days a week, but the output is still in excess of the demand, even in house coal. Although the London market is taking a large tonnage, the agents state that sales are not up to the mark, and that stocks are rapidly accumulating. In consequence of merchants having large supplies in hand, and buying being very limited, sacrifices are occasionally made to get rid of stocks on the rails. The advances which were reported to have been obtained at the beginning of this month are now altogether lost, and prices are about the same as they were in September. The quotations are as follow:—Silkstones are making from 9s. 6d. to 11s. per ton; Barnsley house coal is at 8s. 6d. to 9s. 6d. per ton; second qualities being obtainable at the low rate of 8s. per ton. Steam coal is in steady demand for the season of the year, and prices are fairly well maintained. The Humber ports are still receiving extensive supplies, and there is no doubt that the large amount sent to Hull and the other ports last month will be fairly approached when the October return is out. Hull and Goole, the two chief ports, are reported to be taking freely from the district pits. Barnsley hards made from 7s. 9d. to 8s. 6d. per ton; second qualities ranging from 7s. per ton. Gas coal is in fairly good demand, mainly on account of contracts; prices are well maintained, being at 7s. to 8s. per ton. Manufacturing fuel is in the same depressed condition as when last reported, and no improvement can be reported. Good slacks are at present making from 4s. 6d. to 5s. 6d. per ton; pit slack from 3s. 6d. per ton. Smudge and small coal exhibit no change, prices being low and the requirements far less than the supply. Coke is in good demand, and may be quoted at 9s. to 11s. per ton.

The iron trade, if anything, is somewhat weaker, the majority of the large works being but indifferently employed. Hematites range from 50s. to 52s. 6d. per ton, according to brand, and forge iron 38s., both delivered in Sheffield. Swedish brands still maintain the advance of half-a-crown which was imposed when English iron went up a few weeks ago, but unless a change for the better comes in trade the extra half-crown will no doubt be taken off. Bessemer billets are quoted at £5 10s., bar iron £5 10s. to £5 15s., wire rods £5 5s., rope rods and high carbon rods £8 8s. Very little is doing in railway and shipbuilding material. Railway companies are generally short of supplies of all kinds. It is impossible, therefore, that they can continue to hold their hands much longer, as the railway extensions in hand will compel them to increase their rolling stock. For the new Sheffield, Manchester, and Lincolnshire line to London, the company's works at Gorton are making adequate preparations. One of the orders to be executed at Gorton is no less than one million chairs for the permanent way.

A decided improvement is still maintained in the cutlery trade with the United States. The call is chiefly for the medium qualities of pen and pocket cutlery, which have received most benefit from the new tariff. Table cutlery and the higher classes of spring knives are in somewhat better request, but not to the extent anticipated. It is believed that the ultimate effect of the new tariff will be averse to Sheffield by fostering home production. But several years of good trade are looked for before that comes about. Manufacturers of silver and electro-plated goods are very busy at present, the season trade having set in most satisfactorily. There is a slight upward tendency in silver, which is quoted this week at 2s. 5½d. per oz.

Sir Ughtred Kaye Shuttleworth, M.P., Financial and Parliamentary Secretary to the Admiralty, visited the Cyclops Works of Messrs. Charles Cammell and Co. on Saturday. The Persian Minister, Mirza Mohamed Ali Khan Ala Es Saltane and family accompanied him. Sir Frederick Mappin, Bart., M.P., was also of the party. Mr. Alexander Wilson, J.P., managing director, conducted the visitors over the various establishments. They witnessed the rolling of a very large armour plate for the first-class battleship Mars, and the other processes of bending and finishing similar plates, together with several structures erected in the shops for H.M.S. Magnificent. At the Grimesthorpe Works the party witnessed the casting of a sixty-ton ingot, intended for the production of another armour plate for the Mars. The working of the 6000 tons hydraulic forging press was seen in operation for another armour plate, also intended for H.M.S. Mars. The production of steel shells for the War Department was afterwards witnessed. Sir Ughtred expressed his pleasure and surprise at the ease with which the huge masses of steel were dealt with, and the rapidity with which the company were completing the armour ordered for the Magnificent and other new vessels to be added to the Navy. The same day the Persian Minister visited the cutlery works of Messrs. Joseph Rodgers and Sons, and witnessed the processes of cutlery manufacture. The Persian Ambassador and suite had previously visited the works of Messrs. Mappin and Webb, Norfolk-street, where they witnessed the beautiful process of silver manufacture, electro-plating, &c.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

IT cannot be said that any change for the better has appeared in any branch of the iron and allied industries, and prospects are not encouraging, especially in the finished iron and steel trades. The recent improvement affected these trades, but very slightly, and prices have generally during the last few weeks lost much more than they gained; indeed, steel plates are now being sold at lower figures than were ever before known; in fact, they can be got at cheaper rates than iron plates, and thus the experience of the rail trade is being repeated in the plate trade —steel being cheaper than iron.

The steel plate mills are not kept fully employed, though it is to be borne in mind that the shipbuilding industry, which provides them with the bulk of their orders, is in an exceptionally dull condition, many of the builders having half their berths unoccupied, and a sorry winter for the workmen seems probable, for there is nothing in freights to induce owners to contract for more vessels, seeing that they cannot find profitable employment for those they have, and a large number of steamers are laid up on our rivers. At Whitby, however, the shipyard which has been for a long time idle has just been reopened. For steel ship-plates £4 15s., less 2½ per cent. f.o.t., has been generally quoted this week, and business has been reported at £4 12s. 6d., less 2½ per cent. f.o.t.—a price lower than has ever before been taken, and at least 10s. less than was being quoted a few weeks ago. Materials and labour have not come down in anything like the same proportions, so that the situation for steel plate makers has distinctly become worse, and shortness of orders has led to very keen competition, especially with the Scotch producers, whom North of England makers are underselling in their own markets. Iron ship-plates cannot well be had under £4 15s., less 2½ per cent. f.o.t., and leaves no profit at that. Iron ship angles are about £4 12s. 6d., less 2½ per cent. f.o.t., and steel angles are quoted half a crown higher, but both can be bought at less, though competition is not so keen as it is in the plate trade. Common iron bars have for several months been kept at £4 17s. 6d., less 2½ per cent., f.o.b., and though the mills producing them are not well off manufacturers adhere to the old quotations, and are undersold in some markets by the Belgians. Work at the steel rail mills is fairly active, but does not leave anything in the way of profit. The closing of the Darlington Steel and Iron Company's rail mills has thrown 800 men out of work, and to relieve the distress following on this the poor law authorities have decided to open a stoneyard for married men with families.

The final step in connection with the dispute between the moulders and their employers in the North of England has this week been reached. The men struck work in March last for an advance of 3s. per week, which claim they subsequently modified to 2s., and they were idle for nearly five months, when an arrangement was made that a Conciliation Board should be formed, which would deal with the men's claim, and also with the claim of the employers for a reduction of wages. The Board has decided that no advance is to be given. None could, however, be expected when the present state of trade is taken into account. Though it is nearly two months since the strike ended, many of the moulders are still idle, as the masters have lost so many orders that they cannot find employment for them. The pattern makers in the district continue on strike for 3s. per week advance in wages, and have been idle since the beginning of April, but in spite of the hopelessness of their case, they will not budge from their original demand, or allow the matter to be settled by conciliation or arbitration.

Pig iron makers in the North of England find business very quiet, but as competition is less keen they are able to keep up their prices. It was expected in the earlier part of this week that prices would have been easier, as is usual towards the end of a month, seeing that then speculators who find themselves unable to accept deliveries due to them in that month sell to those who can, and generally at less than the regular price. But there has been less of that than usual, and no further reduction in prices can be reported. The speculators seem to be in no hurry to sell, as, though the quietest period of the year is at hand, it is thought that prices will not fall materially below the present figures, and probably may show some improvement towards the middle of this month, when frequently there has been a spurt in demand and better prices, especially if the weather has been favourable enough to allow of large shipments. Holders of pig iron, either makers, merchants, or speculators, seem in no hurry to sell at present, but at the same time consumers hesitate to purchase for forward delivery.

The general quotation for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. pig iron is 35s. 9d., but rates have been made at 35s. 7½d. Cleveland warrants have fluctuated very little during the last three weeks, the difference between the highest and lowest prices being not more than about 2½d., and a little more is being paid this week than last. The closing figure on Wednesday was 35s. 8½d. cash. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday evening was 88,631 tons, the decrease for October being 1114 tons. Of hematite pig iron Messrs. Connal and Co. also held 70,657 tons, an increase of 7891 tons for the month. No. 1 Cleveland pig iron is in smaller request, now that the northern navigation season is over, and it has been sold at 37s. 6d., while No. 4 foundry is at 35s., and grey forge at 34s., all for prompt f.o.b. delivery, but 33s. 9d. has been taken for the last named. East Coast hematite pig iron is in better supply than demand, and mixed numbers can readily be got at 42s. 9d. for prompt f.o.b. delivery. The prospects are not good for producers of hematite iron, because of the close of the navigation season, and local consumption will be reduced on account of the unsatisfactory condition of the steel plate industry. Foreign ore is somewhat cheaper, because freights have further declined, the rate Bilbao-Middlesbrough being now 5s.; Bilbao-Tyne, 4s. 10½d.; Bilbao-Stockton, 5s. 1½d.; Carthagena-Middlesbrough, 8s. 9d. Good Rubio ore can now be bought at 12s. per ton delivered Tees. The October pig iron shipments from the Tees amounted to 80,159 tons, as compared with 80,139 tons in September, 1894, and 95,673 tons in October, 1893, large deliveries having been made to Baltic ports.

The engineering industries are very quiet; in fact, some firms declare they have never known business so slack, and it is the exception to find full work being carried on at any establishment. Ironfounders give similar reports, as also do the bolt and nut manufacturers, but bridge builders are fairly well occupied, and a fair trade is done by wagon builders.

The coal trade is less active than it was, and some of the collieries do not work as regularly as they did in the summer, while for steam coal the price is lower, 10s. 6d., f.o.b., being asked for best Northumberland. Another improvement has this week been completed at Tyne Dock, which is the largest coal shipping dock in the world, covering over 55 acres, and shipping last year no less than 6,026,694 tons of coal. The improvement which the North-Eastern Railway Company on Wednesday inaugurated is the deepening of the sill of the chief entrance so as to admit the very largest vessels afloat. The entrance is now 70ft. wide, and has a depth of 32ft. at ordinary spring tides and 27ft. at neaps. The deepening of the sill, the dredging of the dock, and other allied works, advised by Mr. Wolfe Barry, have been carried out by Messrs. Lucas and Aird, and have been in progress over three years.

The traders, &c., of Sunderland appear to have a grievance against the North-Eastern Railway in respect to the way that large town is treated by the company, which has the monopoly of the carrying trade of the district. On Monday a public meeting was held in response to a petition presented to the Mayor and very numerously signed by commercial men. The Mayor presided, and the meeting passed a resolution declaring that the Central Station is altogether inadequate and unsuitable, while the facilities for travelling and for goods and mineral traffic need considerable revision and extension. Further negotiations are to be carried on with the railway authorities, and if satisfactory arrangements are not made the Board of Trade and the Railway Commissioners will probably be appealed to. As far back as April, 1888, a deputation waited upon the directors of the railway at York, but nothing has been done.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been comparatively quiet this week. Business has been done in Scotch warrants from 42s. 7d. to 42s. 6d. cash, in Cleveland from 35s. 7d. to 35s. 6d., and in Cumberland hematite at 43s. 6d., these figures in each case representing the slight decline of 1d. per ton, compared with the closing rates of last week.

The demand for makers' special brands is moderate. Nearly all those brands that disappeared from the market during the strike are again obtainable, although in no case is the quantity on offer believed to be large. Prices are steady as follows:—G.M.B. f.o.b. at Glasgow, No. 1, is quoted 44s. per ton; No. 3, 42s. 6d.; Monkland, No. 1, 45s. 6d.; No. 3, 42s. 6d.; Coltness, No. 1, 56s. 6d.; No. 3, 51s.; Summerlee, No. 1, 54s.; No. 3, 48s. 6d.; Calder and Gartsherrie, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Carnbroe, No. 1, 47s.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 57s. 6d.; No. 3, 51s. 6d.; Glengarnock at Ardrossan, No. 1, 54s. 6d.; No. 3, 48s. 6d.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington at Ayr, No. 1, 48s. 6d.; No. 3, 46s. 6d.

A large number of additional furnaces have been put in blast since last week, and there are now blowing at Gartsherrie twelve, Coltness eight, Eglinton, Govan, and Summerlee five each, Dalmellington, Calder, and Carnbroe, four each, Clyde and Wishaw three each, Shotts two, and Monkland one, the total in operation being 56, compared with 32 last week and 43 in the corresponding week of last year.

There is already a considerable improvement in the amount of the pig iron shipments, which are 5178 tons, against 6358 in the same week of 1893. Of the total there was shipped to the United States 175 tons, South America 500, India 103, Australia 1048, France 135, Italy 120, Germany 1260, Holland 245, Belgium 10, China and Japan 185, other countries 230, and coastwise 1167, against 2415 in the corresponding week.

The market for malleable iron is somewhat more active, but there is yet much room for improvement. Makers feel that coal is hardly yet cheap enough to enable them to enter upon the manufacture with confidence, and there is no great pressure of orders to force up prices. The steel trade is getting fairly well employed, but prices are very unsatisfactory, and only a few of the companies are understood to be able to make any considerable profit.

The circumstances of the Steel Company of Scotland have engrossed a good deal of attention on 'Change and in commercial circles this week. The statement was circulated a few days ago, and has since been confirmed, that Mr. James Riley, who has been the principal manager and backbone of the company almost since its commencement, had resigned his appointment and accepted that of general manager to the Glasgow Iron and Steel Company. The Glasgow Iron and Steel Co., of which Mr. Riley now takes the management, has amongst its proprietors one or two very enterprising men, who have lately been engaged in extending and renewing its plant. It is still a small affair compared with the Steel Company, but much may be expected from the influence and energy of Mr. Riley in the future.

The export trade in iron and steel manufactured goods, as measured by current shipments, would seem to be in a very unsatisfactory condition. It is to be hoped, and it may no doubt better the case, that the exports have now reached the lowest point from which we may reasonably look for recovery. They embraced locomotives worth £9200; sewing machines, £4945; other machinery, £2619; steel goods, £933; and miscellaneous iron goods, £7230.

A rapid improvement is taking place in the coal trade both in the inland and shipping departments. The shipments from Scotch ports in the past week reached 110,516 tons, showing an increase of 22,000 tons on the preceding week. The markets in Glasgow, Ayrshire, and in the Eastern colliery districts, keep wonderfully firm. The colliers are now all at work, all of them who can obtain places; but the production is limited by a variety of causes, chief among which is the state of disrepair into which the roads and workings fell during the strike, so that the output is fully absorbed and prices are maintained.

During the past month there were launched from the Clyde shipyards twenty-six vessels of 34,893 tons, compared with twenty-one vessels and 42,731 tons in October, 1893. The output for the ten months embraces 211 vessels aggregating 286,999 tons, against 212 vessels and 243,862 tons in the corresponding period of last year. It is worthy of notice that, of the twenty-six vessels put into the water during October, no fewer than nineteen are steamers.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE long-expected "boom" in tin-plates, to be followed by a rush for tin-bars, which would give a good momentum to business at the principal steel works, is still delayed, and in the meanwhile there is no marked activity at mills and furnaces.

On Tuesday there was a meeting of the Sliding Scale Committee of the iron and steel trades held at Abergavenny, when the report of the audit for the three months ended September was read, indicating no change in wages. It was tolerably certain that it would not justify an advance, and there is a small degree of comfort in the fact that it does not warrant a reduction. Probably the next audit may slightly alter matters, though this week a serious rumour is spreading in the tin-plate trade that some employers are contemplating a reduction of wages.

Welsh ironmasters have unquestionably to contend with severe competition. I note this week that Maesteg has imported 330 tons of tin-plate bars; and two cargoes of steel billets, one of 600 tons, have come into Port Talbot from Middlesbrough. Swansea imported large cargoes of pig iron from Harrington and 200 tons of steel scrap during the week, and 165 tons of iron slag. The only iron cargo of the week from Wales has been 100 tons of pig iron for Rio de Janeiro.

In the matter of pig iron Welsh ironmasters hold large stocks, and all are well provided with foreign ore for winter use. This week a considerable quantity have come in to Blaenavon, Cyfarthfa, and Dowlais, and moderate quantities for Neath, Swansea, and the West generally. Hence, with a tranquil labour market, and good supplies at hand, substantial business can be met if it will only come in.

The coal trade has not quite recovered tone, and prices are slightly weaker than last week. A good deal of this is due to the disturbed weather, which has delayed the arrival of tonnage at all ports, Cardiff and Swansea in particular.

The latest report from the Exchange, Cardiff, is to the effect that there is a good steady attendance, but that the business transacted is not in keeping. Midweek the demand was only moderate, and best steam was easily obtainable at 11s. 3d. to 11s. 6d.; seconds were selling at 10s. 9d. to 11s.; best Monmouthshire, 10s. 3d. to 10s. 6d.; seconds, 9s. 6d. to 10s.; small, 4s. 6d. to 5s. The price of small is a significant one.

House coal is fairly brisk; quite an average demand for this time of year is sustained, and prospects for this class of coal are regarded as good. Latest prices, Cardiff, for best house were 11s.; No. 3 Rhondda, 10s. 3d.; brush, 8s. 3d. to 8s. 6d.; small, 6s. 6d. to 6s. 9d.; No. 2 Rhondda, 8s. 9d.; through, 6s. 9d. to 7s.; small, 4s. 9d.

Most of the large coal contracts remain unsettled, though I believe a few days will see a clearance. It was stated on 'Change, this week at Cardiff, that an important order had been received from the Egyptian Railways by Milburn and Co., of Newcastle and Cardiff. The total is about 100,000 tons, and the stated figure is 15s. c.i.f. A local authority discussing this remarks that the present freight to Alexandria is about 4s. 9d., but that the average for the year would certainly be more than this. Probably it might be taken at 5s. 6d. This would leave the contract price for the coal at 9s. 6d., and that double screened and f.o.b. Last year the contract was taken by Watts, Ward, and Co., Newport and Cardiff. I fancy there must be some misapprehension on the part of the local authority somewhere, possibly in estimating the freight too high. If the freight has been secured at 4s. 9d., the price would not be out of the way.

The colliers are moving in a very undemonstrative way, and chiefly by the action of their representatives, to bring about an organisation that shall include the great body of men in Monmouthshire and South Wales. This number is now estimated at 100,000, a formidable army of labour, if under uniform direction, and a power for good or evil, as it might be directed.

On Tuesday there was a meeting of the representatives at Cardiff. The muster was a full one, only Mabon being absent, from illness. This was to be regretted, as his temperate and peace policy is often effectual, especially when, as in the present instance, the General Federationists are at work. After a discussion the following resolution was carried: — "That the parties here assembled are of opinion that the time has arrived when one common cause is essential and necessary for the whole of the workmen of South Wales and Monmouthshire; and we, as representatives of the various districts, pledge ourselves to do all in our power to establish a general organisation for the whole of the Monmouthshire and South Wales coal field." Later on it was agreed to have a general conference of miners at Cardiff on the 26th November, when the following points will be submitted:—(1) To consider the best means of organisation; (2) to recommend that all workmen organise in each district, and become affiliated into one general association; (3) that a uniform subscription of 1s. per month be adopted; (4) that contributions be paid by the men, and not deducted through the colliery office.

There is a sting in the tail of this, which is evidently meant to show that colliers wish to act independently of their employers. I do not, however, believe that it is intended to "affiliate" on to the General Federationists, and, if not, some mode of working in unison with the sliding scale principles may be arrived at.

There is no improvement to report in the price of tin-plates, and though shipments continue large, they are fairly equalised by the quantity sent from works, thus leaving stocks little altered. Last week the shipments from Swansea were close upon 80,000 boxes; received from works, 73,092. Present stock, 231,472 boxes, as compared with 237,658 this day week, and 261,212 boxes this time last year.

Swansea harbour returns show by a decrease of 10,000 tons, compared with the previous week, the violence of the storms which have assailed the Welsh Coast. In all likelihood, with the lull, there will be a good spurt in of vessels. Last week the shipments of patent fuel were 4880 tons, Italy taking 3200, Algeria 1280, and France 400. Swansea quotations for this manufacture is down to 10s. to 11s.; Cardiff price, 10s. 9d. to 11s. 3d.

General quotations on 'Change Swansea this week are as follows:—Pig iron, Glasgow, 42s. 6d.; Middlesbrough, 35s. 6d.; Welsh bars, £5 2s. 6d.; steel rails—heavy from £3 15s., light from £4 10s.; sheet iron, £6 to £6 10s.; steel, £6 5s. to £6 10s.; Bessemer steel bars, £4 to £4 2s. 6d.; Siemens, £4 to £4 2s. 6d. Tin-plates: Bessemer cokes, 10s. to 10s. 3d.; Siemens, 10s. 3d. to 10s. 6d.; ternes, per double box, 28 by 20 c., 20s. to 24s.; best charcoal, 12s. to 12s. 6d.; wasters, 6d. less. Block tin is advancing, and is now at £67 2s. 6d. to £67s. 7s. 6d. Iron ores: Tafna, 11s.; Rubio from 11s. 3d. Pitwood, 16s. 9d. to 17s. At Cardiff good wood is selling at 15s. Coke prices are unchanged, Cardiff and Swansea.

The Barry and Cadoxton Local Board have succeeded, I hear, in securing a loan for £170,000 at 3 per cent. for the purchase of the gas and water undertakings of the district.

In connection with the Rhondda and Swansea Bay Railway, the line from Aberavon to Neath and Swansea will be opened for mineral traffic at about the middle of November, and for passenger traffic at the end of November.

The extension of the Eagle Tin-plate Works, Neath, has been carried out, and on Saturday last a 500-horse power compound tandem engine and four mills were started under satisfactory auspices. The start was a most successful one, and all that remains for the increase of the producing power of the works is the completion of the gas furnaces.

The Briton Ferry Works have maintained a good average make of pig and tin bar during the week, and a larger make of tin-plate than usual.

There is a hitch in the negotiations between the Cardiff Corporation and the Bute Dock Company about the value of waste land, which, though of little use now, may become very valuable.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

GENERALLY, the position of the iron market remains very much what it has been for some time past. In a few instances makers are reported to be in a stronger position as regards their order books, but, on the whole, specifications come forward very indifferently.

In Silesia the pig iron business continues very dull and stocks are slowly accumulating, so that the damping down of blast furnaces has been taken into consideration. All descriptions of manufactured iron also meet with limited demand, and short time is being worked at some of the mills.

The condition of the Austro-Hungarian iron market is generally quite satisfactory, and a good deal of activity is to be noticed in some branches. The scarcity of pig iron is likely to increase during the coming quarter, as the blast-furnace works which are in course of erection will not be blown in before spring. With a steadily increasing quantity of Silesian iron offering in the market, anything like definite prices are scarcely quotable; in some instances, however, quotations have been tolerably well maintained. A fair employment is reported at the rolling mills; small orders are coming to hand rather freely, and list quotations are generally paid without much questioning. In Hungary, however, a slightly decreasing tendency has lately been perceived for some articles of manufactured iron.

In France the business in iron and steel continues slowly to improve, especially in the Department Nord an increasing liveliness is to be noticed, and both raw and finished iron makers report a fair amount of business doing, but no better prices are obtainable. In the Meurthe-et-Moselle Department foundry pig had to be sold below official quotations, on account of large stocks and of a very keen inland competition. Sheets, as well as all sorts of hardware, continue rather neglected. For the present there is but little life noticeable at the engineering and construction shops.

On the Belgian iron market makers of pig iron have been doing a fair business all through last week. In spite of the continued dulness in the malleable iron trade, the prices for crude iron have shown a decidedly stiffening tendency. During the first two weeks in October Athus has sold more than 22,000 t., and booked further 57,000 t., without going below 44f. p.t. Of the 42 existing blast furnaces, 29 were in blow on October 1st, 14 producing forge pig, 3 foundry pig, and 12 producing basic. Output of pig iron in September and for the first nine months of the present year was:—

| | September. | | January to October. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | t. | t. | t. | t. |
| Forge pig .. | 36,600 | 32,400 | 300,240 | 291,600 |
| Foundry pig .. | 6,600 | 6,300 | 59,400 | 56,700 |
| Basic .. .. | 34,500 | 19,500 | 310,800 | 175,500 |
| Total.. .. | 77,700 | 58,200 | 670,440 | 523,800 |

The iron business in the Rhenish-Westphalian district is decidedly weak, and few contracts are being secured. The prices makers receive for their products are still ridiculously low, and there is little chance of obtaining higher rates. The different sorts of iron ore are in quiet but regular request, and the old prices of M. 7·40 to 7·70 p.t. for spathose iron ore, and M. 10 to 11 p.t. for roasted ditto, are still firmly maintained. Minette of Lorraine is in lively demand, and fetches M. 2·40 to 2·60 and 3·20 p.t. at mines.

There is really scarcely any alteration to be noticed in pig iron. Prices have been well maintained, thanks to the firmness in the coal trade. The Siegerland Pig Iron Convention has sold a fair quantity within the course of last week. Spiegeleisen, 10 to 12 p.c. grade, fetches M. 52 p.t.; Rhenish-Westphalian forge pig, No. 1, M. 46 to 47 p.t.; No. 3, M. 40 p.t.; Siegerland good forge quality, M. 44; hematite, M. 63 p.t.; foundry pig, No. 1, M. 63; No. 3, M. 54 p.t.; basic costs M. 45 p.t.; German Bessemer still stands at M. 49 to 50 p.t.; iron for making steel, M. 45 p.t. at works. Luxemburg forge pig is quoted 48f. p.t. free Luxemburg.

Manufactured ironmakers are short of orders in all branches, and there is for the present little prospect of better employment. Bars and girders are exceedingly quiet just now, and there is nothing doing in the hoop trade. Heavy plates are regularly called for, and give promise of a better market; while sheets, generally, are rather neglected.

The railway and engineering industries continue but very indifferently off for work. Here and there orders are reported to be coming in more freely; but this does not represent an improvement of a general character, and the outlook for the future can scarcely be said to show any really better prospect.

Latest list quotations, per ton at works, are as under:—Good merchant bars, M. 103 to 105; angles, M. 120; girders, M. 90 to 95; hoops, M. 108 to 113; billets in basic and Bessemer, M. 75 to 80; heavy plates, for boiler-making purposes, M. 150; tank do., M. 135; steel plates, M. 120 to 125; tank do., M. 120; sheets, M. 140; Siegen thin sheets, M. 125. Iron wire rods, common quality, M. 115 to M. 120; drawn wire in iron or steel, M. 105 to M. 115; wire nails, M. 125; rivets, M. 150; steel rails, M. 112 to M. 115; steel sleepers, M. 106; fish-plates, M. 110 to M. 120; complete sets of wheels and axles, M. 270 to M. 280; axles, M. 220; steel tires, M. 215 to M. 230.

The total production of pig iron in Germany, including Luxemburg, was for September, 1894, 473,070 t., of which 130,270 t. were forge pig and spiegeleisen, 37,841 t. Bessemer, 221,245 t. basic, and 83,714 t. foundry pig. Production in September, 1893, was 410,193 t.; in August, 1894, it amounted to 489,211 t. From January 1st to September 30th, 1894, no less than 4,088,246 t. were produced, against 3,646,873 t. for the same period the year before.

During the third quarter of present year output of coal in the mining district of Rheinland-Westphalia amounted to 10,337,835 t., against 9,846,114 t. during the third quarter in 1893, and against 9,619,787 t. in the second and 10,089,455 t. in the first quarter of 1894. Consumption was 10,323,709 t., against 9,845,658 t. during the third quarter of 1893, and against 9,579,326 t. in the second and 10,054,362 t. in the first quarter of 1894. The number of men employed was 150,948, against 145,578 in the third quarter of 1893, and against 150,119 for the second, and 153,349 for the first quarter of 1894. Total production for the first three-quarters of present year amounts to 30,047,077 t., or 1,750,739 t. more than during the same period last year; consumption was 29,957,398 t., or 1,693,289 t. higher than in 1893; average number of colliers employed was 157,472, or 6731 more than for the first three-quarters of 1893. Considering the heavy output in the present quarter, total production for 1894 is sure to not only reach but even exceed 40 million tons. In 1893 output was 38,613,146 t. only.

## LAUNCHES AND TRIAL TRIPS.

The turret deck steamer s.s. Progressist was launched from the yard of Messrs. William Doxford and Sons, of Sunderland, on the 27th ult., having been built to the order of Messrs. Angier Bros., of London. She will receive the highest class in both British Corporation and Bureau Veritas Registries.

On the 29th ult., Messrs. Ropner and Son launched a steel screw steamer of the following dimensions, viz.:—Length over all, 285ft. 6in.; breadth, 39ft. 6in.; depth moulded, 19ft. She will be classed 100 A1 at Lloyd's, and carry 3000 tons deadweight on 18ft. with Lloyd's freeboard; she has been built on the part awning decked rule, with break poop and raised quarter deck, cellular bottom for water ballast, and will have all the latest improvements for quick loading and discharging. Her triple expansion engines are by Messrs. Blair and Co., of 750 indicated horse-power, with two large steel boilers working at 160 lb. She has been built for Danish owners, and the name of Harald was given to her by Miss Nielsen of West Hartlepool.

On Saturday, the 27th ult., the s.s. Claverley left the Cleveland dockyard of Sir Raylton Dixon and Co., Middlesbrough, for the official trial trip. She is a fine spar-decked steel screw steamer, and has been built to the order of Messrs. Edmund Haslehurst and Co., of London, for their South African trade. The construction of the vessel has been carried out under the superintendence of Captain A. Bice, the consulting engineers being Messrs. Jacobs and Barringer, of London. The principal dimensions are:—Length, 322ft. 6in.; beam, 40ft. 6in.; depth moulded, 27ft. 11in., with a deadweight carrying capacity of 4650 tons. The main deck is of steel, the spar, poop, and topgallant forecastle decks of iron, and the bridge deck is of wood. She is rigged as a fore-and-aft schooner with steel masts, the pole topmasts being fitted with Sidgwick's patent hinge arrangement for quickly lowering when passing under low bridges, such as those on the Manchester Ship Canal, &c. The engines have been fitted by the North-Eastern Marine Engineering Company, of Sunderland, the diameter of cylinders being 23in., 36in., and 57in., by 42in. stroke, with two extra large steel boilers working at 160 lb. pressure per square inch. Notwithstanding the strong wind and high sea prevailing during the trip, everything worked in a most satisfactory manner, and the steamer afterwards went into West Hartlepool to complete her cargo.

ENGINEERING SOCIETY, KING'S COLLEGE, LONDON.—A general meeting was held on October 12th, when Mr. Kelsall read his presidential address on "Photography in Natural Colours." The author explained the processes of Ives and Lippman, and described, with diagrams, the photo chromoscope of the former, he also touched on three-colour printing. A discussion followed. A general meeting was held on October 19th, when Mr. Droop read a paper on "Forced Draught," giving detailed accounts of the development of the various systems, and treating of their applications both to marine and land boilers. A discussion followed.

ECONOMICAL ENGINES IN TIN MILLS.—At the Eagle Tin-Plate Works, Neath, on Saturday last, a new engine and four mills were added to the three already at work there. These were supplied by Messrs. Taylor, Struve, Eaton, and Price, of Neath and Briton-Ferry. The engine is a horizontal tandem compound, with cylinders 28in. and 50in. diameter, with a stroke of 4ft., driving two mills on each side of the cranked shaft; while running at forty revolutions per minute they will indicate nearly 600-horse power with the full load on. The valves of both cylinders are of the Cornish type: the high-pressure valves are controlled by a high-speed governor and a cut-off trip gear the firm has very successfully applied to their tin mill engines, as it ensures the steady running of the mill, however intermittent the work, and also a great saving in fuel over many other kinds of gears used in South Wales. The tin-plate trade of South Wales is now being so sorely pressed by America, and countries on the Continent, that the makers of the Principality are bound to adopt every means to save fuel, and it is only within the last few years that the use of high-class engines of this sort have been entertained.

BRITISH MACHINERY AND METALS IN JAPAN.—According to a recent Foreign-office report for railway locomotives, of which there has been an increased import, the Japanese private railway companies are beginning to have recourse to the United States, and in at least one recent instance a private railway company disposed of several of their English-built engines to the Government, supplying their place with newly-imported American engines at a cost greatly in excess of the proceeds realised by the sale of the old ones. The import of machinery increased last year by £225,290, or 150½ per cent. over that of the previous year. The imports of spinning machinery, £258,000, are nearly all English, and it is hoped that if the trade continues there will not be any falling off in the English share of it. The import of metal increased by £16,998, or 22·7 per cent., and was distributed over nearly all the several items included under the heading, except iron and nails, which substantially decreased. The continued construction of railways has caused a considerable demand for iron rails, which is likely to be maintained for some years to come. So far the attempts of the Japanese to compete with imported metal manufactures have not been marked with such success as will induce any general repetition of them. The requirements of the trade, viewed from the standpoint of the producers in Europe, seems full of promise. England's share in the trade of 1893 amounted to £598,000, or 65¼ per cent., her principal competitors having been Belgium and Germany. In other articles the figures were—Locomotives and railway carriages, £43,000, or 62⅓ per cent.; steam boilers, £19,000, or 90 per cent.; steamers, £91,000, or 76½ per cent.

## THE PATENT JOURNAL.

19,783. Permanent Way for Railways, T. F. Cashin, Hastings.
19,784. Screw-propellers, B. W. Maughan, London.
19,785. Combined Gas Burner, &c., H. Drueding, London.
19,786. Stuffing-boxes, D. B. Morison, London.
19,787. Flushing Apparatus, J. Breeden and Co. and F. Breeden, London.
19,788. Attachment of Paper Hangings, A. Markmann and J. H. Wetjen, London.
19,789. Chain-stitch Sewing Machines, F. R. Brauer, London.
19,790. Hydraulic Tires, O. Wartmann, London.
19,791. Picks and their Attachments to Shafts, T. Brown, London.
19,792. Bath Slippers, E. Edwards.—(*S. Kuttner, Germany.*)
19,793. Mercurial Vacuum Pumps, E. P. Clerc, London.
19,794. Propelling Mechanism for Velocipedes, T. C. Dennison, London.
19,795. So-called Forster Pipe-joint, C. Burnett, London.
19,796. Manufacturing Wheel Rims, C. M. Moore, London.
19,797. Zinc-coated Wire, The Cowper-Coles Galvanising Syndicate, Limited, and S. O. Cowper-Coles, London.
19,798. Hand Signal Lamps, A. V. Linley and W. H. Owensmith, London.
19,799. Edging Machines, E. and R. Cornely, London.
19,800. Bolting Mills, H. Ménager, London.
19,801. Brakes of Cycles, D. Marston, London.

18th *October*, 1894.

19,802. Foundations for Artificial Fringes, C. Richards and F. Horsnell, Westminster.
19,803. Collapsible Drinking Vessel, H. Lamplough, London.
19,804. Metallic Bedsteads, S. I. Whitfield, Birmingham.
19,805. Implement to Grip Stretched Wire, J. Messer, Germany.
19,806. Destination Indicators, W. T. Brown, London.
19,807. Electric Door Contact, H. Oppenheimer, London.
19,808. Hoof Pad, T. Cloke and W. J. Standbrook, London.
19,809. Fastener for Rubber Mats, S. Moss, London.
19,810. Railway Fog-signalling, J. G. Barras, Newcastle-on-Tyne.
19,811. Tiring, J. L. and W. C. Jones, Dublin.
19,812. Lighthouse Lights, J. R. Wigham, Dublin.
19,813. Attaching Sash Cords to Windows, S. Cooper, London.
19,814. Hydro-extractors, H. C. Longsdon, Keighley.
19,815. Manufacture of Fuel-blocks, H. Tempest, Keighley.
19,816. Attachment of Pneumatic Tires, W. H. Cresswell, Woodley.
19,817. Drum for Working Dredger Buckets, J. A. Saner, Liverpool.
19,818. Potato Cooker, C. Smart, Birmingham.
19,819. Box-irons, A. S. Jones, Birmingham.
19,820. Securing Pneumatic Tires, J. Clinch, Manchester.
19,821. Twin Crane, W. Purdy, Leeds.
19,822. Displaying of Goods, R. Sedgwick, Birmingham.
19,823. Bottle Metallic Mounts, T. Morton, Birmingham.
19,824. Pulverising Ores, P. B. Bradley, London.
19,825. Hair Curlers, A. H. Godfrey, Birmingham.
19,826. Action of Guns, H. Middleton, Birmingham.
19,827. Corkscrew, I. F. de L. Latoix.—(*Applicant's father, United States.*)
19,828. Chocolates, X. Marb and J. Bechtle, Glasgow.
19,829. Tubular Bricks, J. Tulloch, Glasgow.
19,830. Manufacture of Cardboard Boxes, J. M. Baines, Halifax.
19,831. Manufacture of Fustians, T. Holt and The New Victoria Spinning and Manufacturing Company, Manchester.
19,832. Hydro-extractor, T. Cudlipp, London.
19,833. Mixing Liquids, G. Field, Birmingham.
19,834. Coal Screen, W. E. Kochs, Chesterfield.
19,835. Machines for Corking Bottles, J. P. Jackson, Liverpool.
19,836. Counter Fountains, J. P. Jackson, Liverpool.
19,837. Bottling Carbonated Beer, J. P. Jackson, Liverpool.
19,838. Applying Colours to Tinned Plates, R. Read, A. Read, W. Eedle, and C. Masters, Liverpool.
19,839. Pneumatic Tires, J. McLaren and D. Shanks, Glasgow.
19,840. Comb Cylinders of Combing Machines, T. W. Harding, Leeds.
19,841. Fire-boxes, &c., of Boilers, W. Malam, Manchester.
19,842. Electric Storage Fuse Distribution-box, L. H. Cline, Wallsend-on-Tyne.
19,843. Valves for Regulating Flow of Liquids, C. H. C. Rudd, Walker-on-Tyne.
19,844. Discharging Products of Combustion, E. L. Burne, Guildford.
19,845. Gas Regulators, J. Paterson, London.
19,846. Steering Cycles, T. J. Biggs, Kildare.
19,847. Composition for use on Streets, N. Davies. —(*G. F. and S. P. Davies Australia*)
19,848. Retaining the Hair in Curl, M. Wedlake, London.
19,849. Pocket Metallic Match-boxes, R. P. Brown, London.
19,850. Toy Doll, A. M. Douglas, Birmingham.
19,851. Construction of Finger-plates, P. C. Bunn, London.
19,852. Cycles, R. Thompson, W. J. Freeman, and E. Freeman, London.
19,853. Pedalling Mechanism, W. J. and E. Freeman, London.
19,854. Seats, S. M. Birnie, Boscombe.
19,855. Adjustable Pulley, D. Speirs and J. Schmidlin, Manchester.
19,856. Wood-moulding Machinery, E. Youell, London.
19,857. Portable Structures for Polling Stations, C. R. Lapthorne, London.
19,858. Paint for Mirrors, A. J. Boult.—(*G. Philippe, Belgium*)
19,859. Boots, E. M. Scott, Liverpool.
19,860. Driving Gear for Velocipedes, J. S. Miller, London.
19,861. Brace Buckles, &c., F. and S. Taylor, Manchester.
19,862. Machines for Buffing Boots, W. R. Mudd, London.
19,863. Oars, H. Ferns, Liverpool.
19,864. Gas-glowlight Cylinder, M. Epstein, London.
19,865. Treatment of Frozen Carcases, J. Atherton, Liverpool.
19,866. Regulating the Pressure in Pumps, V. Montalto, London.
19,867. Curtain Rods, S. A. Stevens, London.
19,868. Electro-deposition Process, W. A. Thoms and W. H. Burgum, London.
19,869. Camphor Substitutes, J. E. T. Woods and W. J. Birnie, London.
19,870. Cash Registering Appliances, C. S. Snell, Saltash.
19,871. Attaching Labels to Bottles, T. S. Bunney, London.
19,872. Lemon-squeezing Apparatus, J. E. Harris, London.
19,873. Provision and other Knives, L. G. Rogers, London.
19,874. Hay Rakes and the like, J. H. Dugdale, London.
19,875. Metallic Teasels, G. Scrive and A. Scrive, London.
19,876. Concentrating Alkalies, &c., J. Armstrong, London.
19,877. Electrically-heated Grills, F. W. Schindler, London.
19,878. Cycle Cane Frames, T. Baylis and E. Perks, jun., Birmingham.
19,879. Construction of Coiled Wire Fabric, G. Watson, Birmingham.
19,880. Advertising on Vehicles, H. S. Dark, London.
19,881. Water-level Gauges for Boilers, V. Petherick, London.
19,882. Apparatus for Working Butter, R. Waide, London.
19,883. A New or Improved Fire-escape, J. E. Seary, London.
19,884. Band Saws, T. W. Bloxam, London.
19,885. Colouring Matters, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
19,886. Delivering Paper Sheets, G. and A. E. Watson, and A. McLaren, London.
19,887. Automatic Weighing Apparatus, M. E. Reisert, London.
19,888. Capillary Manometers, O. Steinle, London.
19,889. Electric Arc Lamps, C. T. Praed and P. R. Allen, London.
19,890. Iron-frame Pianofortes, M. J. Christie, London.
19,891. Door Spring, J. N. Maskelyne, London.
19,892. Fire-resisting Material, J. V. Boyd-Wilson, London.
19,893. Sewing Machines, A. S. Strutt, London.
19,894. High-speed Gas Engines, H. G. Harris, London.
19,895. Golf Scorer, C. M. Page, London.
19,896. Adjustable Skirt Fastener, C. G. Wright, London.
19,897. Railway Signalling Devices, J. J. Boyd, London.
19,898. Gearing for Bicycles, D. Lamont, London.
19,899. Treatment of the Hair, R. Haddan.—(*J. de Bouffard, Spain.*)
19,900. Steelyards, C. H. Bartlett, London.
19,901. Corkscrews, W. F. Williams, London.
19,902. Registering the Level of Water in Boilers, C. Strutt, London.

19th *October*, 1894.

19,903. Holders for Gas Globes, H. Edwards, Bristol.
19,904. Umbrella Protectors, S. B. Weaver, Melton Mowbray.
19,905. A Tubular Puddle Buller, A. F. Wilson, Stirlingshire.
19,906. Construction of Incubators, J. A. Hooper, London.
19,907. Reversing Gear for Washing Machines, W. E. Baker, Aldershot.
19,908. Cotton Machinery, J. Lobley, Ramsbottom.
19,909. Armour-plating, T. J. Tresidder, London.
19,910. Wood-block Sawing Machine, T. B. Marchant, London.
19,911. Hat-pegs for Railway Carriages, J. S. Pearce, Southampton.
19,912. Ships' Berths, W. P. Hoskins, Birmingham.
19,913. Boilers, C. S. Galloway, Glasgow.
19,914. Skates, D. H. Shuttleworth-Brown, London.
19,915. Cotton Preparing Machinery, T. Brooks, Manchester.
19,916. Wheels for Road Vehicles, T. and T. Wood, Manchester.
19,917. Stretching Frames for Garments, C. Goddard, Lytham.
19,918. Automatically Basting Meat, W. E. Bryan, Lyndhurst.
19,919. Counters, W. Chadburn, Liverpool.
19,920. Device for Holding Bed clothes, W. O'Mara, Liverpool.
19,921. Post card, J. Baldwin, King's Norton, near Birmingham.
19,922. Bread Tin or Plate, G. G. Mander, Birmingham.
19,923. Self-acting Mules, J. Clegg, Manchester.
19,924. Bedsteads, J. W. Hoyland and W. H. Sturge, Birmingham.
19,925. Stoking Steam Boiler Furnaces, F. Paget, Glasgow.
19,926. Making Boots and Shoes, F. W. Francks, Leicester.
19,927. Fog Signalling for Railways, W. B. Williamson, Bradford.
19,928. Fasteners for Placquets, B. Williams, Birmingham.
19,929. Bobbins for Spinning, B. W. Stevens and R. Whitaker, Birmingham.
19,930. Hand Shearing, &c., Machinery, A. Muir, Glasgow.
19,931. Fastening the Heads of Mops, R. Allen, Manchester.
19,932. Manufacture of Carpets, W. C. Gray, Glasgow.
19,933. Flushing Cisterns, M. J. McNamara, Birmingham.
19,934. Producing a Porous Mass for Electric Accumulators, G. Hubner, London.
19,935. Instruments for Stretching Carpets, A. Lunn, Edinburgh.
19,936. Duplex Vaporiser, A. H. Damkoehler, London.
19,937. Fabric Machines, J. M. and W. Starley, Coventry.
19,938. Preventing Fingers being Jammed in Doorways, F. C. Cawdell, Barnsley.
19,939. Engine Piston Valves, N. Browne.—(*H. J. Head, India*)
19,940. Railway Danger Indicator, P. Bergna, Sunderland.
19,941. Manufacture of Singe Plates, W. Sumner, London.
19,942. Flower-show Board, F. W. Littlewood, Sheffield.
19,943. Bicycles, G. J. Bowcock, London.
19,944. Water-tight Pipe Joints, R. Malabar, Liverpool.
19,945. Cycle Gear, J. R. Park, Norwich.
19,946. Safety Button, H. S. Knight, Teignmouth.
19,947. Cycle Driving Gear, A. Campbell, Glasgow.
19,948. Mechanical Stokers, A. Thomson, Glasgow.
19,949. Curer for Smoky Chimneys, H. H. Bridgman, London.
19,950. Dough-moulding Machines, G. Lewis, London.
19,951. Lamp Wick Trimmers, H. V. Rippingille, London.
19,952. Valves for Steam Engines, C. W. Thomson, London.
19,953. Combination Air Pillow and Rug, G. N. Cheetham.
19,954. Bottle Stoppers, W. J. Kelly and E. T. Whitelow, Manchester.
19,955. Locking Cycle Steering Bars, F. Brookes, Birmingham.
19,956. Sink Traps, W. Calvert, London.
19,957. Carving Forks, A. Heald, London.
19,958. Knicker for Married Ladies, M. Beadelle, London.
19,959. Recording, &c., Mechanical Motions, W. Nicolajczuk, London.
19,960. Torpedo Guard for Warships, F. L. Rovedino, London.
19,961. New Drain-testing Machine, J. Armstrong, London.
19,962. Paper for Cutting-out Patterns, A. Ferry, London.
19,963. Tires and Fastenings for Same, T. Thornton, London.
19,964. Hanging Lamps, R. H. Best and F. Hewitt, London.
19,965. Fire-arms, G. Luger, London.
19,966. Supplying Electrical Energy, H. Birnbaum, London.
19,967. Attachment to Crochet Hooks, H. Gründler, London.
19,968. Saponaceous Compound, H. Whitbread, London.
19,969. Transmitters for Sewing Machines, J. White, London.
19,970. Colouring Matter Manufacture, C. D. Abel. —(*The Actien Gesellschaft für Anilin Fabrikation, Germany*)
19,971. Colouring Matter Manufacture, C. D. Abel. —(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
19,972. Colouring Matter Manufacture, C. D. Abel. —(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
19,973. Hat Pins, W. B. Allison and R. P. Smith, London.
19,974. Type-writers, E. A. Jeffreys and W. Edwards, London.
19,975. Knitting Machinery, S. Lowe, London.
19,976. Utilising Waste Water, E. Larsen.—(*The Berliner Actiengesellschaft for Eisengiesserei and Maschinenfabrikation vormals J. C. Freund and Co., Germany.*)
19,977. Drilling Machines, W. W. Hulse, London.
19,978. Machinery for Filling Bottles, E. S. Chavasse, Birmingham.
19,979. Umbrella and Walking Stick, T. Ashford, London.
19,980. Pneumatic Tires, P. Davies, London.
19,981. Valve Mechanism, Tangyes Ld., and W. Johnson, jun., London.
19,982. An Adjustable Toast Frame, J. T. Hunt, London.
19,983. Xylonite Tablet, J. W. Marshall and H. E. Webster, London.
19,984. W.C. Flush Cisterns, &c., W. Edwards, London.
19,985. Polishing Paste for Metals, M. A. Capp and M. L. Bailey, London.
19,986. Vessels for Fluid Foods, J. Jörgensen, London.
19,987. Making Alimentary Product, J. Escuyer, Liverpool.
19,988. Water-proof Garments, I. Frankenburg, Manchester.
19,989. Steam Boiler Furnaces, J. W. Stock, Manchester.
19,990. Railroad Tie Anchors, The Daniels Steel Railroad Tie Company, Liverpool.
19,991. Couplings for Railways, A. Roth, London.
19,992. Heating Air, E. A. Jeffreys and W. Edwards, London.
19,993. Frying Pans, E. Colley, London.
19,994. Stamping Rivet Holes, R. Knights and H. Rigby, London.
19,995. Tobacco Pipes, L. L. Samuel, London.
19,996. Rain-water Shoots for Houses, T. B. Gibbs, London.
19,997. Front Cone Reflectors for Cycle Lamps, H. Salisbury, London.

20th *October*, 1894.

19,998. Teapots, E. H. Durnford, Hawley.
19,999. Steel Heck Frame, G. A. Binns and J. C. Hill, Sheffield.
20,000. Ventilating Contents of Saucepans, H. M. Fletcher, Ramsgate.
20,001. Driving Gear of Cycles, J. J. Atkinson, Northamptonshire.
20,002. Guide-posts, J. E. Brown, Hampshire.
20,003. Food for Cattle, B. R. Phillipson, Dublin.
20,004. Catapult Bagatelle, P. Diamond, Sheffield.
20,005. Knotting Mechanism, J. Hornsby, J. Innocent and I. Trolley, Grantham.
20,006. Radial Arm Operator, N. J. McAuslan, Derby.
20,007. Horse-shoe, I. C. Stuart, Cardiff.
20,008. Roundabouts, A. G. Bingley and J. L. Lister, Manchester.
20,009. Spring Resisting Power, E. C. Ibbotson, Sheffield.
20,010. Tooth Brush, P. J. Vetter, London.
20,011. Indicating Speed of Engines, W. Chadburn, Liverpool.
20,012. Self-oiling Bearings, F. M. Newton and T. Hawkins, London.
20,013. Laundry and Pressing Irons, H. S. Myers, Leeds.
20,014. Ironing Stoves, T. Cudlipp, London.
20,015. Round Game, F. Gill, Kingstown.
20,016. Parlour Game, J. M. Gillies, Dundrum.
20,017. Regulating Arc Lamps, A. G. New and A. J. Mayne, London.
20,018. Spanners, J. Bradbury and W. B. Lake, London.
20,019. Turning Cycle Hubs, &c., A. E. Herbert, Coventry.
20,020. Construction of Bottles, H. Edye, Newcastle on-Tyne.
20,021. Coal and Bread Weigher, J. Moreland, Nottingham.
20,022. Sparkling Wines, J. Y. Johnson.—(*E. L. Doyen, France*)
20,023. Adhesive Composition, &c., J. Round, Birmingham.
20,024. Chaff-cutters, J. G. Richmond, Manchester.
20,025. New Child's Mail-cart, F. Aldous, Manchester.
20,026. Case Hardening Wire, M. A. Mosley, Wakefield.
20,027. Means of Connecting Pipes, R. Wigan, Manchester.
20,028. Door Stop and Spring, W. M. Ralph, London.
20,029. Save-all for Necks of Bottles, C. G. Dolmage, Dublin.
20,030. Contrivance against Slipping, U. Prussf, Berlin.
20,031. Self-acting Lid for Closets, F. Müller, Berlin.
20,032. Self-feeding Hot-water Cylinder, A. Mackenzie, Liverpool.
20,033. Wool Yarns, &c., J. L. and B. F. Byrom, Manchester.
20,034. Spliced Joints for Golf Clubs, L. H. Smith, Glasgow.
20,035. Attachable Shovel Plates, J. Dawson, Sheffield.
20,036. Dress and Mantle Fasteners, L. Bryan, Cardiff.
20,037. Lock for Bicycles, &c., W. Sturmey, Birmingham.
20,038. Road Carriages and Vehicles, H. Höhmann, London.
20,039. Cigar, H. J., A. S., and G. A. Spratt, London.
20,040. Showing Clothing Stuffs, W. Lünser, London.
20,041. Gears for Cycles, J. Foxcroft, A. Blanchard, and H. Wood, London.
20,042. Heating Curling Irons, &c., G. Skinner, London.
20,043. Arc Lamps, W. Geipel, London.
20,044. Consulting-room Couch, J. R. Whait, London.
20,045. Sieves, A. J. Boult.—(*F. Brandstaedter, Belgium.*)
20,046. Meter Indicators, W. P. Thompson.—(*P. Marix, France*)
20,047. Shields for Soles of Boots, E. and S. W. de Horsey, Liverpool.
20,048. Diving Apparatus, T. Thomson, Liverpool.
20,049. Ladles, &c., C. Hildebrand, London.
20,050. Crucibles, J. W. S. Holt and S. Hargreaves, Liverpool.
20,051. Paper Tubes, W. P. Thompson.—(*M. C. Stone, United States.*)
20,052. Tires for Wheels, F. Sulley and W. E. Dowson, London.
20,053. Billiard Cues, W. P. Wethered, Great Marlow.
20,054. Folding Opera Glass, E. Bloch, London.
20,055. Street Gully, W. Calvert, London.
20,056. Burners for Gas Stoves, C. Gerlach, Birmingham.
20,057. Attaching Saddles to Cycles, H. Mills, Birmingham.
20,058. Removing Subaqueous Deposits, J. Corbett, London.
20,059. Casting by Electric Current, P. Scheidt and J. W. Tideman, Berlin.
20,060. Potatoe Rasp, R. Flemming, Berlin.
20,061. Door Fastener for Retorts, J. Mitchell, London.
20,062. Skirt Suspenders, C. Wood, London.
20,063. Pneumatic Tires, O. Wartmann, London.
20,064. Velocipedes, R. S. Lovelace, London.
20,065. Driving Chains, C. Powell, London.
20,066. Carburetting Coal Gas, W. E. Price, London.
20,067. Carburetting Armour-plates, F. Stubbs, London.
20,068. Ball Castors, T. Mawson and J. B. Blamires, London.
20,069. Cutting Indexes to Books, E. A. Goddin, London.
20,070. Blind Roller, R. Bolton and E. F. Lackerstein, London.
20,071. Coating Metals with Tin, L. Bangert, London.
20,072. Unsiltable Harbours, W. S. Randall and J. C. Gilmour, Kent.
20,073. Crank for Driving Cycles, A. Prunier, London.
20,074. Driving Gear for Cycles, E. Eite and A. Todd, London.
20,075. Manufacture of Metallic Brackets, G. Whitehouse, London.
20,076. Seat for Chairs, B. Clarke and H. C. Willmott, London.
20,077. Oil Lamps, C. F. R. A. H. Bagot, London.
20,078. Liquid Hydrocarbons, C. F. R. A. H. Bagot, London.
20,079. Securing Pneumatic Tires, F. H. Sprang, London.
20,080. Appliances for Obtaining Light, P. Stiens, London.
20,081. Telegraphic Transmission, C. Langdon-Davies, London.
20,082. Shoes for Horses, The Mail Horse Shoe Syndicate, C. J. Jutson and F. A. Poupard, London.
20,083. Coin-freed Apparatus for Liquids, W. Sherar, London.
20,084. Cigarette Making Machines, C. A. Marchal, London.
20,085. Ships' Side Lights, T. Utley, London.
20,086. Manufacture of Cellulose, A. Levinstein, London.
20,087. Apparatus for Cooling Wort, F. N. Mackay, London.
20,088. Bottle Filling Machinery, A. P. Blaxter, London.
20,089. Cycle Tires, D. Doig, London.
20,090. Ornamenting Metal Surfaces, G. Williams and F. H. P. Berlyn, London.
20,091. Pulpers, E. C. Blackstone, J. Kelly, sen., and J. J. Kelly, jun., London.
20,092. Cycle Tires, S. Chandler, jun., J. Chandler, and J. J. Chandler, London.
20,093. Incandescent Gas Burners, G. F. Redfern.—(*La Compagnie Parisienne du Bec Deselles-Gillet, France.*)
20,094. Indicating Dates, G. Hayes, London.
20,095. Magic Lanterns, W. H. Tomkinson, London.

22nd *October*, 1894.

20,096. Lug or Clip for Cycles, J. E. Meredith, Birmingham.
20,097. Handle-bars for Cycles, W. E. Hart, sen., Wolverhampton.
20,098. Cycle Chain Protector, W. E. Hart, sen., Wolverhampton.
20,099. Apparatus for Polishing Boots, C. Sadler, Manchester.
20,100. Tramcar Seats, C. Challenger and W. Strong, Bristol.
20,101. Hat Peg, E. Savill, London.
20,102. Junctional Parts for Cornice Rods, C. Snowell, Birmingham.
20,103. Machines for Pressing Bricks, T. C. Fawcett, Halifax.
20,104. Attachment for Cork Drawers, W. Manson, Birmingham.
20,105. Instruments for Measuring, B. Davies, Liverpool.
20,106. Wire Mattresses, I. Chorlton and W. Oldham, Manchester.
20,107. Washing Printers' Blanket, J. Hawthorn and J. P. Liddell, Manchester.

20,108. Method of Advertising, J. J. Gillespie, Newcastle-on-Tyne.
20,109. Concentrators of Minerals, W. H. Penning, Sussex.
20,110. Controlling the Twist Bands of Spinning Mules, E. Smethurst, Manchester.
20,111. Fire-screen and Table Combination, F. W. Reckitt, Harrow.
20,112. Seat for Velocipedes, W. C. Heighton and J. Meek, Leicester.
20,113. Potters' Kilns, H. Cartlidge, Longport.
20,114. Brakes for Spindles, A. Hitchon and J. Lucas, Accrington.
20 115. Covers for Gear of Cycles, W. Bramham, Keighley.
20,116. Clasp Fastenments for Apparel, W. Evans, Birmingham.
20,117. Postage-stamp Machine, W. W. G. Webb, Lichfield.
20,118. Labelling Bottles, G. A. Thornhill and F. Pardy, Stapleford.
20,119. Measuring-scales, O Schubert, Berlin.
20 120. Fixing Brush Handles, W. Butterworth, Manchester.
20,121. Cotton Thread, J. Y. Johnson.—(*L. F. Gros, France*)
20,122. Printed Woven Fabrics, J. Y. Johnson.—(*L. F. Gros, France.*)
20,123. Gas Motor, T. R. Shillito—(*The Leipziger Dampfmaschinen und Motoren Fabrik, Germany.*)
20 124. Metallic Bedsteads, C. Greenwood, Manchester.
20,125. Buttonhole for Collars, &c., J. H. Palmer, London.
20,126. Fixing Blocks to Electrodes, M. M. Bair, London.
20,127. Porous Pot for Batteries, M. M. Bair, London.
20,128. Watchmakers' Lathes, &c, C. F. Lorch, London.
20,129. Indoor Game, A. W. Thorneycroft, Ayr.
20,130. Imparting Elementary Instruction, &c, J. W. P. West, London.
20,131 Stereoscope, F. J. Jeans, London.
20 132. Draught Detainer for Doors, H. M. Lucas, Surrey.
20,133. Manufacture of Inlaid Floor-cloth, R. M. Harvey, London.
20,134. "Naval War" Game, E. H. W. von Niessen, London.
20,135. Knotters for Sewing Machines, A. W. Cochran, London.
20,136. Door-stop and Holdfast, F. Hughes, London.
20,137. Churns, E. A. Goodchild, London.
20,138. Manufacture of Pottery, &c., E. A. Shaw, London.
20,139. Glove, E. Watts and W. Godden, London.
20,140. Instrument for Measuring Hands, T. Nestler, London.
20,141. Signalling on Railways, F. Nowell, London.
20,142. Belts for Curved Pulleys, N. Browne.—(*P. Schivner, Germany.*)
20,143. India-rubber Pipe Mender, J. J. Deans, London.
20,144. Detachable Sleeve Shirt, T. A. Moody, London.
20,145. Manufacture of India-rubber, L. Wolff, London.
20,146. Cushion Horseshoe, A. Trewin, Watford.
20,147. Pendulum Frame for Advertisements, A. L. Summers, Surrey.
20,148. Steam Boilers, J. McLaren and H. McLaren, London.
20,149. Letter Files, J. C. Fell.—(*B. Lawrence, United States.*)
20,150. Knitted Fabrics, T. Hill, G. Matthews, and E. Goddard, London.
20,151. Pads for Trusses, &c, J. A. Calantarients, London.
20,152. Incandescent Electric Lamps, V. Fabris, London.
20,153. Coin-actuated Machines, A. J. Boult.—(*W. S. Burnett, United States*)
20,154. Tires for Cycle Wheels, L. B. McCulloch, Liverpool.
20,155. Composition for Pavements, J. O. McQuone, London.
20,156. Fireproof Lining for Furnaces, &c., E. W. Crebbin, Liverpool.
20,157. Mixing and Kneading Machines, P. Küpper, London.
20,158. Making Soft Soap, M. Perls, Liverpool.
20,159. Typewriters, A. C. Moll, London.
20,160. Showcard, A. Grice, Liverpool.
20,161. Gun-mountings, A. J. Boult.—(*The Bethlehem Iron Company, United States.*)
20,162 Weighing Apparatus, A. W. Gattie and L. Greene, London.
20 163. Furnace Grates, M. Fitz-Michael Mulready, London.
20,164. Pipe, C. V. McBean, London.
20,165. Metal Sleepers for Railways, G. Trasenter, London.
20,166. Metal Sleepers for Railways, G. Trasenter, London.
20,167. Refrigerating Apparatus, F. N. Mackay, London.
20,168. Producing Chromates, W. L. Wise.—(*Deutsche Solvay-Werke Actien-Gesellschaft, Germany.*)
20,169. Producing Manganates and Stannates, W. L. Wise.—(*Deutsche Solvay-Werke Actien-Gesellschaft, Germany*)
20,170. Electric Welding Apparatus, H. Zerener, London.
20 171. Footballs, W. Howard, J. F. Sadler, and W. H. Dallimore, London.
20,172. Metal Joists, W. H. Aston, London.
20,173. Ploughs, W. H. and R. H. Sleep, London.
20,174. Device for Facilitating Writing, W. F. Fair, London.
20,175. Process and Apparatus for Distillation, O. Perrier, London.
20,176 Type, G. W. Weaver, London.
20,177. Propelling and Steering Boats, &c., T. B. Heathorn, London.
20,178. Treatment of Petroleum, R. Schewe and F. Messedat, London.
20,179. Gilling or Combing Machines, C. Cholerton, London.
20,180. Envelopes, Wrappers, &c., W. E. Fisher, London.

*23rd October*, 1894.

20,181. Carriers for Magic Lanterns, G. Davenport, London.
20,182. Chess Timing-pieces, T. Grosse, Sale.
20,183. Screws used in Rigging Boats, G. E. Hughes, Wolverhampton.
20,184. Telescopic Luggage Carrier, A. McCormack, Portarlington.
20,185. Silk Trainer for Moustache, W. H. Wooler and F. H. Phillips, Weston-super-Mare.
20,186. Doll's Dresses, J. H. Maden, Manchester.
20 187. Driving Pulleys, J. G. A. Kitchen, Manchester.
20,188. Automatic Petrolier, J. Collins, Leamington
20,189. Fumigating Apparatus, M. Rymer-Jones and L. Swaby, London.
20,190 Boring Machine, A. Gray and G. Tarbit, Stockton-on-Tees.
20,191. Wet Spinning Frames, H. M. Girdwood, Manchester.
20,192. Hydrocarbon Engines, J. Grove, Paisley.
20 193. Mirror Spectacles for Ladies' Hair-dressing, C. E. Roberts, Liverpool.
20,194. Football Toy, W. Chaffer, Halifax.
20,195. Signalling on Railways, W. Kershaw, Leeds.
20,196. Cycle Wheels, W. Birks, F. Walker, and H. Rylands, Nottingham.
20 197. Gas Furnace, J. Heaton and G. H. Holden, Manchester.
20,198. Celluloid Cycles, J. B. Short, J. B. Short, jun, and T. J. Tomlinson, Sunderland.
20,199. Packing of Valve Spindles, J. Green, Liverpool.
20,200. Watch Keys, W. T. Smith, Birmingham.
20,201. Commercial Reels, H. P. Trueman, Birmingham.
20,202. Gas Purifiers, J. Entwisle.—(*W. L. Wallis, United States.*)
20,203. Coin-actuated Machine, J. P. Beretta, Manchester.
20.204. Detectors, T. Shevels and R. Simmon, Durham.
20,205. A New Game and Board, C. H. Abbot, London.
20,206. Spring Expansion for Cuffs, J. W. Baron, London.
20,207. Extracting Moisture from Air, J. Johnson—(*J. Galey, United States*)
20,208. Ball Bearings, I. M. W. Burke, London.
20,209. Food Warmer, C. Anderson, London.
20,210. Carriages, S. Cooper, London.
20,211. Loom Picking Bands, J. H. Morley, London.
20,212. Unicycle, F. H. Pickering, London.
20,213. Appliance for Washing Glasses, W. H. Greenwood, Southport.
20,214. Automatic Vent, R. H. Walker, Derbyshire.
20,215. Apparatus for Propelling Bodies, G. Wilson, London.
20,216. Horn Horseshoes, R. Aspinall, London.
20,217. Aluminium Tips for Boots, G. Mahaffy, London.
20,218. Manufacture of Articles T. Birnbaum, London.
20,219. Syphon-filling Machines, J. R. Lofthouse, Barnsley.
20,220. Bottle-corking Machines, J. R. Lofthouse, Barnsley.
20 221. Watermarking Paper, Henderson, Craig, and Co, and E. Rutley, London.
20 222. Spring Tires for Cycles, &c., A. Wadham, London.
20 223. Electrically-worked Pumps, R. L. Howard, London.
20 224. Devices for Cleaning Knives, E. A. Pike, London.
20,225. Machine Potato Diggers, R. Rosbotham, Liverpool.
20,226. Pen and Pencil Protectors, A. Harrison, London.
20,227. Anchors, W. Coltart and E. Shore Liverpool.
20,228. Menstrual Pad, N. B. Paul and E. Grahame, London.
20 229. Photographic Film Spool, J. B. B. Wellington, High Barnet.
20,230. Portable Advertisement Frames, H. Fabian, London.
20,231. Vices, J. L. Carpenter and W. M. Harris, London.
20,232. Loom Motions, H. Ainsworth, London.
20,233. Boot-jacks, H. Löwe, London.
20,234. Manufacture of Bricks and Tiles, H. Wood, St. Alban's.
20,235. Apparatus for Quieting Horses, A. Nowak, London.
20,236. Tobacco-stripping Machines, H. H. Lake.—(*S. Reid, United States.*)
20,237. Paper Board Scoring Machines, C. W. Gay, London.
20,238. Printing Machines, H. H. Lake.—(*C. B. Cottrell and Sons Company, United States.*)
20,239. Tack-driving Implements, H. H. Lake.—(*W. T. Hoofnagle, United States.*)
20,240. Positive Shuttle Motions, E. H. Graham, London.
20,241. Alternating Current Motors, H. H. Lake.—(*E. A. Clark, United States.*)
20,242. Making Wheel-hub Blanks, W. W. Tucker, London.
20,243. Automatically-acting Pump, N. Paissiadis, London.
20,244. Boot and Shoe Studs, W. Maddock, London.
20,245. Portiere Rods, R. Hodges and C. Johnson, London.
20,246. Bellows, T. Wallen, London.
20,247. Metallic Alloy, D. W. Sugg, London.
20,248. Tiles for Floors and other Surfaces, F. Furness, London.
20,249. Pneumatic Wheels and Tires, F. King. London.
20.250. Manufacture of Paint, &c, J. Armstrong, London.
20,251. Ventilators, J. Armstrong, London.
20,252. Garden Pump, F. B. Hill and R. D. Brett, London.
20,253. Enriching Gas, P. C. Tennant and J. E. Hall, London.
20,254. Harness for Horses, J. A. Thompson, London.
20,255. Paper-pulp Beating Engines, J. D. Pickles, London.
20,256. Pile Fabrics, J. Reixach and F. Bamford, London.
20,257. Apparatus for Cutting Buttonholes, L. Neville, London.
20,258. Bottle-stopper Extractors, E. W. Robinson and N. M. Marshall, London.
20,259. Electrolytic Apparatus, C. Kellner, London.
20.260. Smoke-consuming Fireplaces, G. W. Kraft, London.
20.261. Plushes, E. Edwards.—(*P. Kottlors, Germany*)
20,262. Busts for Measuring Garments, W. A. and A. L. Arfvidson, London.
20,263. Digestive Compounds, J. Carnick, London.
20,264. Cleaning Bottoms of Ships, G. S. Scorer, London.
20,265. Portieres, N. Vinall, London.
20,266. Construction of Pump, P. E. Jammes, London.
20,267. Bits for Horses, T. Pierpoint, London.
20,268. Banners, C. Matthews, London.
20,269. Protectors for Hay Ricks, R. Rottenbury, London.
20,270. Machines for Cleaning Grain, A Schnetzer, London.
20,271. Rubber Blanks, J. Spyer, London.
20,272. Iron Sewer Wagon, C. W. Smallbone, London.
20,273. Sash Locks, E. A. Abrams, London.
20,274. Screw Bolt, A. Mosley, London
20,275. Screw Propellers of Steamers, W. Ledden, London.
29,276. Nail Brushes, W. E. Deere, London.
20,277. Stockings, J. Park, London.
20,278. Stoppering Bottles, A. M. Gibson, London.
20,279. Valve Water-closets, E. H. Morton and H. E Baden, London.
20,280. Cartridge-filling Machines, P. Kämmerer, London.
20.281. Producing Nitropentaerythrite, B. Thieme, London.
20 282. Attachment for Sewing Machines, W. F. McGennis, C. Henwood, and F. S. Hammett, London.
20.283. Lock-nut, P. R. J. Willis.—(*J. A. Wells, United States*)
20 384. Delivering Parcels, J. T. Andrews and R. Knights, London.
20,285. Manufacturing Seamless Tubes, S. Briggs, London.
20,286. Upholstery, A. Balestre, London.

*24th October*, 1894.

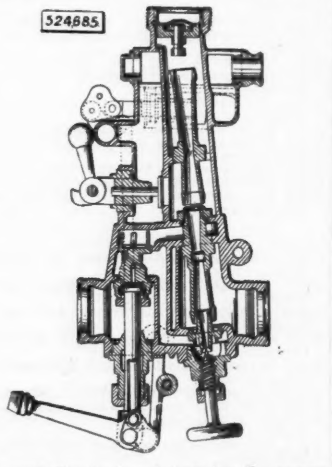
20,287. "Transfers," J. Slater and A. Doulton, Staffordshire.
20,288. Figure Bottle Holder, C. O. Brown, London.
20,289. Conversion of Rectilinear into Rotatory Motion, S. Butler, London.
20,290. Explosive Projectiles, H. V. Keeson, London.
20,291. Parlour Football Game, T. Thompson and W. E. Challis, London.
20,292. Stereotyping, R. H. Turner and J. Whiteley, Manchester.
20,293. Electric Lamp Shades, G. F. Sanders, Birmingham.
20,294. Machines for Excavating Soil, E. Latham, Liverpool.
20 295. Rabbit Coursing Machine, W. H. Best, Plymouth.
20,296. Winding Reels, C. C. Gossage and W. I. James, Birmingham.
20,297. Preventing Colliery Cages Falling, J. Stirland and W. Cottrill, Derby.
20,298. Racks for Tobacco Pipes, C. Laight, Crab's Cross.
20,299. Covers for Ships Hatchways, G. Brown, London.
20 300. Shield for Miners' Lamps, J. N. Guy, Newcastle-on-Tyne.
20 301. Attaching Stencil Sheets to Frames, T. C. Chandler and H. B. Saint, Newcastle-on-Tyne
20,302. Spoon Attachment for Knives, E. Proctor, Derby.
20,303 Photo-holding Calendar, R. G. Evans, Manchester.
20,304. Index-cutting Machine, A. Watkinson and F. W. Musgrave, Leeds.
20,305. Railway Fog Signals, T. Jenkins and S. Illidge, Birmingham.
20,306. Connections of Bands and Belts, P. A. Martin, Birmingham.
20,307. Ink-holding Pen, J. G. Smith and J. Couston, Edinburgh.
20,308. Printing of Cotton Fabrics, W. E. Kay and The Thornliebank Co., Manchester.
20,309. Filter, R. W. Hartley, Manchester.
20,310. Connecting Spindles to Levers, F. T. Jackson, Leicester.
20 311. Wheels of Vehicles, F. T. Jackson, J. and F. Hatton, Leicester.
20,312. Forming Adhesive Letters, H. S. Fearon, London.
20 313. Driving Belt, J. W. Knights and F. W. Bird, Cambridge.
20 314. Canister Shot for Small-arms, W. G. Hay, Liverpool.
20,315. Driving Whip, S. Williams, Oswestry.
20.316. Book-keepers' Hand-rest, C. Clarance, London.
20 317. Glow Lamps, J. R. Mally, London.
20,318. Cigarette, G. Lynn, Kingston-on-Thames.
20 319. Treating Meat and Foods, J. A. Wilson, Dundee.
20.320. Grates for Furnaces, R. H. Williamson and The Direct Automatic Stoker Syndicate, Ld., Manchester.
20,321. Leather Packings, T. Garner, Manchester.
20 322. Driving-gear for Cycles, H. Love and J. S. Braidwood, Glasgow.
20,323. Method of Trawl-net Fishing, W. Adam, Glasgow.
20,324. Wire-netting Machines, T. E. Bond, Birmingham.
20,325. Propulsion of Ships, W. Graham, jun., Manchester.
20,326. Buffer for Umbrella Ribs, G. T. Jones. Llwynypia.
20,327. Pumice Stones, Hubaleck and Co., Cologne.
20,328. Oscillating Fluid Motor, J. S. McAndrew, Glasgow.
20,329. Type-writing Machines, J. N. Williams, Glasgow.
20,330. Electro-magnetic Machines, I. Vago, Glasgow.
20,331. Smoke Consumer in Furnaces, W. Bracewell, Preston.
20,332. Ladders, J. H. Heathman, London.
20 333. Rollers for Sewing Machines, S. Wheeldon, Warwickshire.
20,334. Leaf-turners for Music, E. Richardson, Sheffield.
20,335. Railway Brakes, W. S. Laycock, Sheffield.
20,336. Bottle Openers, J. Hobson, Sheffield.
20,337. Cycle Tires, T. Staines, J. Leadbeater, and A. Preston, Leeds.
20,338. Curtains for Windows, W. J. Riley, Manchester.

## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**524,685.** Injector, *W. R. Park, Taunton.—Filed September 25th*, 1891.

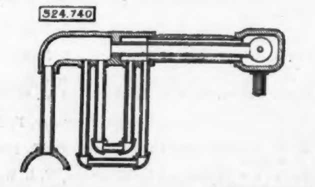
*Claim.*—In an injector the combination of a lifter composed of a steam nozzle and its tube, a forcer composed of an annular steam nozzle and its tube, a main valve controlling the flow of steam into the passages leading to the lifter and forcer, and a regulating valve between the main valve and the lifter and controlling the flow of steam through the passage leading to the lifter, substantially as described.



524,685

**524,740.** Steam Generator Section, *T. L Sturtevant and T. J. Sturtevant, Quincy, Mass.—Filed October 16th*, 1893.

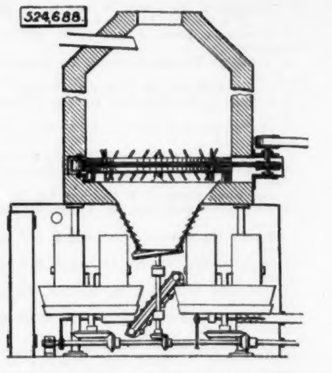
*Claim.*—A steam generator section comprising an outer steam generating tube closed at its upper end, an inner return tube extended within said outer tube and open at both ends, and a series of steam generating tubes which extend laterally within the combustion chamber and connect the upper ends of the said outer and inner tubes, substantially as described.



524.740

**524,688.** Means for Treating City Refuse, *E. L. Ransome, Oakland, Cal.—Filed January 2nd*, 1894.

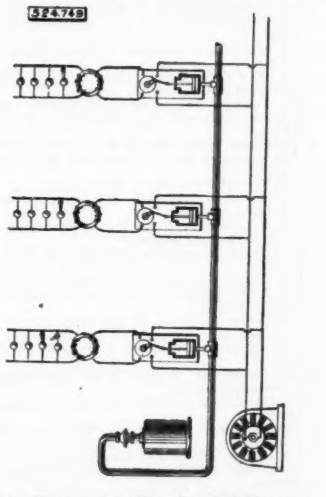
*Claim.*—(1) The combination of a furnace, an air-locked chamber communicating therewith, means for forcing air into said chamber, and clinker-reducing devices located within the furnace and within the air-locked chamber. (2) The combination of a furnace, an air-locked chamber communicating therewith, means for forcing air into said chamber, clinker-reducing devices located within the furnace and within the air-locked chamber, and an air-locked outlet for the reduced material. (3) An apparatus for reducing clinker produced by burning, consisting of a furnace in which the material is burned, a breaker forming a grate for the furnace situated at the lower part upon which the clinker formed by said burning descends, devices upon which the breaker is supported and guided, adjustable breaking bars fixed in openings made through the breaker and projecting upward so as to form contact with the lower surface of the mass of clinker as it descends, and a driving chain and sprocket wheels through which power is transmitted to rotate the breaker.



524,688

**524,749.** System of Electrical Distribution, *G. Westinghouse, jun., Pittsburg, Pa.—Filed June 16th*, 1890.

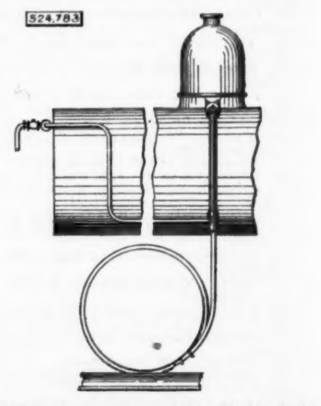
*Claim.*—The combination with a series of electric converters and a circuit for supplying the primary coils thereof, of circuit controlling devices applied to the respective primary coils for opening and closing the circuit connections thereof, and fluid pressure devices for operating said circuit controlling devices, substantially as described.



524,749

**524,783.** Railway-track Sander, *W. G. Middleton, Atlanta, Ga.—Filed April 20th*, 1894.

*Claim.*—(1) In a track sanding device, a casing having a cylindrical chamber therein, a sand-pipe leading from the sand-box to the top of said chamber, a discharge pipe running to a position near the track and led into said chamber so as to lie axially thereof therein, and provided on the end within said chamber with a sidewise extending nipple, and an air-induction pipe leading from an air reservoir into the side of said chamber, opposite the opening of said nipple therein; the end of said air-pipe being offset from the said nipple in such a manner that part of the air will be directed into the same and part caused to circulate in vertical currents within said chamber, substantially as and for the purposes set forth.



524,783

Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided for our breakfast and supper a delicately flavoured beverage which may save us many heavy doctors bills."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, by Grocers, labelled, "James Epps and Co, Homœopathic Chemists, London.'

## MINERAL, METALLURGICAL, AND COAL INDUSTRIES OF SWEDEN IN 1893.

We have received a copy of the official report of the mineral, metallurgical, and coal industries of Sweden in 1893, from which we gain the following particulars. The total production of magnetic iron last year in Sweden amounted to 1,481,487 tons raised from 341 mines, whereas in 1892, when only 353 mines were being worked, the entire output was only 1,291,933 tons. The increase last year is therefore no less than 189,554 tons, or 14·7 per cent., *i.e.*, about one-seventh of the total output in 1892. As regards the yield of ore in ratio to the output of iron-bearing rock, we learn that the total quarrying of the latter amounted to 2,718,354 tons, making an average return of 54·5 per cent. for the eleven iron-producing provinces of the country. In 1892 the rock quarried amounted to 3,312,692 tons, the yield of ore to 1,291,933 tons, and the average return to 55·9 per cent. The ratio of yield varied from 100 (?) per cent. in the furnace of Linköping down to 58·7 in Kopparberg, 55·0 in Norrbotten, and 48·4—the lowest—in Orebro län. Of the total production last year 1,194,298 tons, or 80·6 per cent., were magnetic iron ore and 287,187 tons, or 19·4 per cent., hematite. The latter kind of ore is rare and occurs only in four provinces. The great increase in the output of iron ore in Sweden last year is principally due to the enormous advance in the production from the famous Gellivara iron deposits in the province of Norrbotten, where it rose to 306,594 tons in 1893, as against 178,181 tons in 1892, and only 200 tons in 1891. The output too is steadily increasing, being estimated this year at quite 400,000 tons. The ore is mostly shipped to Westphalia and Silesia, but a considerable quantity goes also now to Great Britain. In the south of central Sweden, too, where are situated the celebrated Grängesberg mines, the output rose from 110,237 tons in 1892 to 182,657 tons in 1893, nearly the entire quantity going to Germany. Only a few years ago these mines were idle through the lowness of prices of ore prevailing abroad. The Gellivara and the Grängesberg iron ores average from about 50 per cent. to 53 per cent. of pure metal. The following table shows the output of iron ore in Sweden since 1861, with increase and decrease, showing that the output last year was the heaviest on record.

| Annually. | No. of mines. | Output. Tons. | Increase or decrease. Per cent. |
|---|---|---|---|
| 1861—1865 | 500 | 453,486 | — |
| 1866—1870 | 422 | 542,323 | + 19·6 |
| 1871—1875 | 576 | 784,707 | + 44·7 |
| 1876—1880 | 382 | 721,232 | − 8·1 |
| 1881—1885 | 496 | 874,423 | + 21·2 |
| 1886—1890 | 530 | 930,037 | + 6·4 |
| 1889 | 393 | 983,609 | — |
| 1890 | 390 | 940,429 | − 4·4 |
| 1891 | 346 | 985,255 | + 4·8 |
| 1892 | 353 | 1,291 933 | + 31·1 |
| 1893 | 341 | 1,481,487 | + 14·7 |

The main output is furnished by five provinces as follows:—Kopparberg, 28 per cent.; Norrbotten, 20·7 per cent.; Orebro, 20·3 per cent.; Vestmanland, 15·8 per cent.; and 10·9 per cent. by Vermland and Upsala län, so that only 4·3 per cent. are returned by the remaining five iron-bearing provinces. During the year there were in operation nine iron ore separators, by which 13,575 tons were treated. There were employed in the iron mines 7510 persons, making an average return per head of 197 tons. And although the number of persons employed has fluctuated considerably during the period under review, the output per head has steadily increased, as the following table will show:—

| Annually. | Number of Mines. | Tons per head. |
|---|---|---|
| 1861—1865 | 5001 | 90 7 |
| 1866—1870 | 4581 | 118·4 |
| 1871—1875 | 6439 | 121 9 |
| 1876—1880 | 4883 | 147·7 |
| 1881—1885 | 6210 | 140 8 |
| 1886—1890 | 6257 | 148 7 |
| 1889 | 6238 | 157·7 |
| 1890 | 6335 | 148·4 |
| 1891 | 6223 | 158·3 |
| 1892 | 7564 | 170·8 |
| 1893 | 7510 | 197·3 |

In addition to magnetic ore there were raised 2275 tons of ore from lakes and bogs in Sweden, as against 1650 tons in 1892. The returns of such ores have varied considerably of late years, and they are steadily declining. These ores are particularly suitable for the production of soft malleable iron. The total ore production in Sweden has been as follows:—

| | Tons. |
|---|---|
| 1861—1865 | 464,363 |
| 1866—1870 | 553,759 |
| 1871—1875 | 795,263 |
| 1876—1880 | 726,712 |
| 1881—1885 | 877,408 |
| 1886—1890 | 932,470 |
| 1889 | 985,904 |
| 1890 | 941,241 |
| 1891 | 987,405 |
| 1892 | 1,293,583 |
| 1893 | 1,483,762 |

Turning to the pig iron industry in Sweden in 1893, we find that 152 furnaces were in blast at 134 works, returning 453,421 tons in 37,276 shifts of twenty-four hours, of which 6059 tons were produced "direct." There were also forty-seven furnaces not in blast. In 1892 the production amounted to 485,664 tons in 37,405 shifts, so that there is an increase of 32,243 tons, or nearly 7 per cent. The production in the period 1861-93 has been as follows:—

| Annually. | Pig iron. Tons. | Direct. Tons. | Totals. Tons. | Increase or decrease. Per cent. |
|---|---|---|---|---|
| 1861—1865 | 199,375 | 5451 | 204,826 | — |
| 1866—1870 | 261,810 | 6044 | 267,854 | + 30·8 |
| 1871—1875 | 326,510 | 5946 | 332,456 | + 24·1 |
| 1876—1880 | 350,414 | 6810 | 357,224 | + 7·5 |
| 1881—1885 | 423,176 | 6201 | 429,377 | + 20·2 |
| 1886—1890 | 441,876 | 4702 | 446,578 | + 4·0 |
| 1889 | 416,043 | 4622 | 420,665 | — |
| 1890 | 451,443 | 4660 | 456,103 | + 8·4 |
| 1891 | 486,680 | 4233 | 490,913 | + 7·6 |
| 1892 | 478,696 | 6968 | 485,664 | − 1·1 |
| 1893 | 447,362 | 6059 | 453,421 | − 6·6 |

The principal decrease in output falls upon the following provinces:—Kopparberg, 13,800 tons; Vermland, 6644 tons; Orebro, 3775 tons; Vesternorrland, 3359 tons; Gefleborg, 2106 tons; Ostergötland, 1638 tons, &c. The falling off varies from 3 to 71 per cent. It is worthy of note that two provinces, Orebro and Kopparberg, have from time immemorial returned more than half of the total pig production of the country. Pig iron is manufactured in thirteen provinces. The average output per furnace for the year was 2983 tons, and the average time of blasting 245 shifts of 24 hours, and the average diurnal return 12·18 tons. The following table shows the average annual output, the average time of blasting, and the average diurnal production during the last five years:—

| Year. | Annual average output. Tons. | Per furnace. Average Shifts. | Average diurnal Tons. |
|---|---|---|---|
| 1889 | 2804 | 239 | 11·73 |
| 1890 | 2962 | 246 | 12 04 |
| 1891 | 3167 | 259 | 12·23 |
| 1892 | 3174 | 257 | 12·35 |
| 1893 | 2983 | 245 | 12·18 |

The largest average annual output is shown by the province of Ostergötland, viz., 3778 tons at four furnaces in blast all the year, and the lowest by Jönkoping, viz., 294 tons. In some counties the average diurnal output was as much as 1430 tons.

The pig iron production of the year was made up as follows:—

| | Tons. | Per cent. |
|---|---|---|
| Forge and puddle iron | 285,718 | 63·86 |
| Bessemer and Martin iron | 145,479 | 32·52 |
| Spiegel iron | 1,294 | 0·29 |
| Pig iron for reduction | 6,922 | 1·55 |
| Pig iron for other purposes | 7,949 | 1·78 |
| Totals | 447,362 | 100·00 |

The first-mentioned kinds of iron are produced in thirteen provinces, varying from 215 tons up to 86,418 tons; Bessemer and Martin in several, but two return 57 per cent. between them.

Malleable iron and steel was produced at 153 works, as against 158 in 1892, situated in nineteen provinces, Orebro and Kopparberg possessing repectively 25 and 21. There were in operation 349 Lancashire hearths, 43 Franche-Comté hearths, and 25 Walloon hearths; whilst in the production of Bessemer metal were employed 30 furnaces, and in the production of Martin metal also 30, with six crucible furnaces. The total returns of raw materials are as follows:—

| | Tons. | Per cent. |
|---|---|---|
| Unwelded blooms and raw bars | 225,532 | 57·4 |
| Unwelded ingot metal | 166,845 | 42·4 |
| Blister steel, &c. | 664 | 0·2 |
| Totals | 393,041 | 100·0 |

Of the total production of blooms, &c., no less than 208,802 tons, or 92·6 per cent., were produced by the Lancashire method, and by the Franche-Comté process 14,942 tons, or 6·6 per cent., were turned out. The output of blooms and raw bars during the last quinquennial period has been as follows:—1889, 226,071 tons; 1890, 225,632 tons; 1891, 224,651 tons; 1892, 235,426 tons; 1893, 225,532 tons. There is therefore a decrease in 1893 of 9894 tons, or 4·2 per cent. The prices of this kind of iron have been low of late years, and the demand has been small. The production of Bessemer steel amounted to 84,398 tons, 50·6 per cent.; of Martin steel to 81,889 tons, 49·1 per cent.; and of crucible steel to 558 tons, 6·3 per cent. The manufacture during the last quinquennial period has been as follows:—

| Year. | Bessemer. Tons. | Martin. Tons. | Crucible. Tons. | Total Tons. |
|---|---|---|---|---|
| 1889 | 80,324 | 55,487 | 513 | 136,324 |
| 1890 | 94,247 | 72,985 | 646 | 167,878 |
| 1891 | 92,985 | 78,197 | 707 | 171,889 |
| 1892 | 82,422 | 76,556 | 617 | 159,595 |
| 1893 | 84,398 | 81,889 | 558 | 166,845 |

The total increase in the production of steel is therefore, in 1893, 7250 tons, or 4½ per cent.—viz., 1976 tons Bessemer, 5333 tons Martin, and 59 tons crucible steel. In these figures are included 23,467 tons of steel produced by the basic dephosphorisation method—viz., 8419 tons Bessemer and 15,010 tons Martin steel.

Coming next to the manufacture of finished iron and steel goods, we learn that the total production amounted to 288,317 tons, as against 293,036 tons in 1892—being a decrease of 4719 tons, or 1·6 per cent. The following table shows the detailed manufacture:—

| | Production. 1892. Tons. | 1893. Tons. | Increase or decrease. 1893. Tons. | Welded. Per cent. | Ingot |
|---|---|---|---|---|---|
| Blooms, billets, &c. | 11,222 | 8,726 | −2496 | 0·5 | 99·5 |
| Bar iron and steel | 145,173 | 146,042 | + 829 | 73·5 | 26·5 |
| Fashion iron and steel | 6,583 | 7,313 | + 730 | 0·7 | 99·3 |
| Hoops and nails | 72,056 | 70,828 | −1228 | 60·1 | 39·9 |
| Wire rods | 38,476 | 33,818 | −4658 | 62·4 | 37·6 |
| Heavy plates | 8,138 | 10,721 | +2583 | 1·2 | 98 8 |
| Rails | 6,627 | 5,677 | − 950 | — | 100·0 |
| Bottom boiler-plates | 1,579 | 1,004 | − 575 | 36·6 | 63·4 |
| Tires | 975 | 1,343 | + 368 | — | 100·0 |
| Axles | 1,223 | 1,640 | + 417 | 29·0 | 71·0 |
| Anchors and cables | 984 | 1,205 | + 221 | 18·7 | 81·3 |
| Total | 293,036 | 288,317 | −4719 | 59·8 | 40 2 |

In 1892 the manufacture of such goods from welded iron was 63·6 per cent., and from ingot metal 36·4 per cent.; so that there is an increase in the manufacture in 1893 by the former of 3·8 per cent. Bar iron and steel were produced in eighteen provinces, the largest returns being as follows:—Vestmanland, 32,888 tons: Gefleborg, 20,642 tons; Kopparberg, 19,718 tons; Ostergötland, 18,030 tons; Orebro, 17,046 tons; Vermland, 15,185 tons; and Upsala, 12,608 tons; the remaining eleven only producing 9925 tons together. Rails are only manufactured in Kopparberg län and tires only in Gefleborg. The production of actual bar iron of all denominations during the last quinquennial period was as follows:—1887, 274,734 tons; 1890, 281,833 tons; 1891, 280,430 tons; 1892, 273,510 tons; 1893, 266,727 tons. It appears that the quantity of bar iron produced by rolling is twice as great as that returned by forging. Of the total output 62,699 tons, or 67·8 per cent., were rolled from hard prepared iron; and 29,733 tons, or 32·1 per cent., from ingot metal; whilst again 39,495 tons, or 91·7 per cent., were rolled from blooms; and 3160 tons, or 7·3 per cent., from welded iron. Vestmanland län shows the greatest production of rolled bars, viz., 23,728 tons; and Orebro the greatest production by forging, viz., 9440 tons.

The production of other metal ores in Sweden in 1893 was as follows:—

| Ores. | No. of Mines. | Production. Tons. |
|---|---|---|
| Gold | 1 | 2,441 |
| Silver | 28 | 21,043 |
| Copper | 13 | 22,033 |
| Zinc | 1 | 101 |
| Manganese | 26 | 46,623 |
| Pyrites of sulphur | 12 | 7,061 |

The production of gold amounted to 93·3 kilos., as against 120 kilos. in 1892; the average annual production is 90 3 kilos. The production of other metals was as follows:—Silver, 4436 kilos. (1892, 5210 kilos.); lead, 462 tons, average 425 tons; copper, 544 tons, average 605 tons.

Finally, the coal industry of Sweden appears to be in a very flourishing condition, nearly 200,000 tons having been raised in 1893. The coals, which are lignite, are only found in the province of Scania, in the extreme south, seven fields being worked. The coals are of no use whatever in the iron industry, but they are largely used on the railways of South Sweden, special grates having been introduced for their burning. The detailed production was as follows:—

| | Tons. | Per cent. |
|---|---|---|
| No. 1 coal | 110,518 | 55·28 |
| No. 2 coal | 70,320 | 35·17 |
| No. 3 coal | 19,031 | 9·52 |
| Refuse | 64 | 0 03 |
| Totals | 199,933 | 100·00 |

The output in the period 1889-93 has been as follows:—1889, 186,719 tons; 1890, 187,512 tons; 1891, 198,033 tons; 1892, 199,380 tons; 1893, 199,933 tons. The number of colliers employed was 1217, as against 1260 in 1892. The motors engaged in these industries numbered 1881 of 61,169-horse power, of which about 50,000 were furnished by water, and 10,000 by steam. The total number of hands employed was 25,811, of whom 11,330 were employed in the mines, 14,481 at works; some 500 women were employed in the iron mines. There were in all forty-nine accidents, twenty-two being fatal.

## THE WATERLOO AND CITY RAILWAY.

One of the most important railway projects that have been carried out for many years within the area known as Greater London is that which is now being pushed forward in and below the bed of the river Thames on either side of Blackfriars Bridge—namely, the Waterloo and City Railway. Passengers by the South-Western Railway have now access to the northern side of the Thames in the City of London, but it is over part of the South-Eastern Railway, and, like some other modes of reaching the City which involve running powers on other lines, the convenience is not as great as it might be. Entrance to Cannon-street from Waterloo is only a makeshift for the better accommodation of the many who are occupied in the City who desire to make use of the South-Western Railway. The service is, for these and other reasons, not much employed as between the City and Waterloo, and the only other access for passengers by the South-Western Railway into the City or near it is *viâ* Wimbledon, Herne Hill, and Ludgate, and thus by a service where there is but one train an hour, and over lines actually or nominally the property of three different railway companies. This service of one train per hour is necessarily incapable of accommodating very large numbers, and the morning and evening trains are already excessively long and crowded, and have to be hauled by engines which are quite heavy enough for the much-repaired bridge over the Thames between Ludgate and Blackfriars. A frequent and rapid service of trains between Waterloo and the City is very much wanted, and has every probability of being well patronised, and in a few years will probably make a great difference in the relative numbers and in the distribution of City men who will reside respectively in the south-eastern and south-western districts.

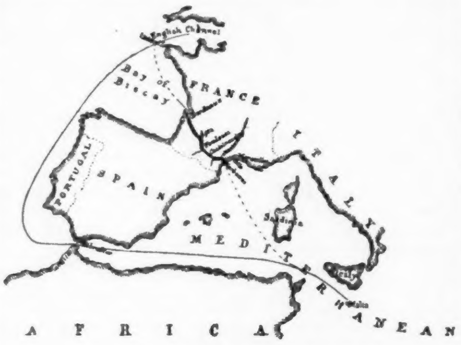
The new railway will be an electrical line, connecting Waterloo Station and the Mansion House. It will be entirely underground, mostly below the bed of the Thames, and the trains will be hauled by electric locomotives. It will be much larger, but much upon the same lines as the City and South London Electric Railway. The up and down lines will be in separate tunnels, connected at the stations and at some intermediate places, as, for instance, at the shafts by which descent is made to the tunnels from the staging now in the river near Blackfriars Bridge, and from which the spoil, nearly all clay, will be raised and deposited in barges for removal. The total length will be about two miles of double or four miles of single lines. The tunnels are 12ft. 1¾in. in diameter, and 12ft. 9in. on short curves where clearance is required.

The new railway is from the designs of Messrs. Galbraith and Greathead, MM. Inst. C.E., the engineers for the line. The contract for its construction has been let to Messrs. Mowlem and Co., who will carry it out under the engineers, and on Greathead's system of tunnel making, with his shields and method of tightly grouting the space between the cast iron tunnel lining and the hole excavated for its reception. Not only is the new railway to be worked by electricity when it is finished, but the contractors are carrying out the work largely by the aid of electricity, and in order that every precaution should be taken and the best means adopted for ensuring the rapid and successful operation of all the necessary plant, the whole of the arrangements have been separately devised. Messrs. Bramwell and Harris are acting as engineers for Messrs. Mowlem and Co. in this matter, and already a large part of the necessary plant for electric lighting and electric operation of the hydraulic pumps for operating the shields are in place, while the arrangements for the electric haulage of the spoil wagons are approaching completion; the locomotives for this work having been placed in the hands of Messrs. Siemens Bros. As many of our readers are aware, the tunnel works have been commenced some few months, a very large and strong staging has been erected a little west of Blackfriars Bridge and on the southern shore, being built on the mud flats usually occupied at low tide by stranded barges. This will be the chief centre of operations for some time, as it has been until now, the progress made already being almost marvellous. Already the two great cast iron lined shafts, each 16ft. diameter, are completed and sunk to the full depth of 78ft. from stage level, and rest in the massive brickwork of a large chamber below the Thames bed, which connects the two shafts, and is also a brickwork commencement of both tunnels in both directions. Two of the shields with their hydraulic presses are in place, and the cast iron shafts are lined with vertical timbers for guiding the tubs to the surface as soon as the excavation commences. Three fine steam cranes command the entrances to the shafts, which have to provide room for pipes to connect with air locks for providing the necessary air pressure for keeping out water when a wet gravelly part is reached. These cranes serve for taking the spoil from below and depositing it in barges alongside the staging, and also for lifting all the structural material, including the cast iron segments forming the tunnels, from barges, and lowering them down the shafts. For providing the compressed air which will be required for the air lock at the shield, a large plant of air compressing machinery will be fixed in the engine and machinery house on the stage. This is being made by Messrs. Markham and Co., of Chesterfield. Already two of Paterson and Cooper's dynamos with vertical engines are in place, each dynamo being capable of giving a current of 120 ampères at a pressure of 100 volts. As the work progresses, further dynamos and engines each of the same size as a unit, namely, 25-horse power, will be put down. For all the underground work, namely, for the hydraulic press motors, for the locomotives, and for the lighting, a pressure of 200 volts will be used—only 100 volts being used for the surface and office lighting on the stage. Three 100-horse locomotive boilers, by Messrs. Davey, Paxman, and Company, are at present ordered, one being already in place, to be supplied with Thames water after passing through a Torrent filter. The compressed air receivers will be placed in the river by the stage, and so cooled without expense. Everything is arranged with a view to carrying this important work through in the best way and at a high speed, and although the mechanical engineer has made all the changes in the modern methods of carrying out works of the kind, this is probably the first in which a firm of consulting engineers has been employed to design the whole of the mechanical arrangements from the first, so that the work shall start as a correlated system of operations and be carried through with mechanical precision and celerity as a piece of work effected by a special combination of machinery and apparatus. Messrs. Mowlem and Co. are to be congratulated on the rapidity with which they have completed a very important part of this undertaking, and also upon the methods of procedure which have been devised for them. These should undoubtedly lessen the cost of construction.

## THE FRENCH CANAL DES DEUX MERS.

The French Government has, after a great deal of pressure, at last consented to appoint a commission to examine the project for a ship canal from the Atlantic to the Mediterranean. This scheme has long had a fascination with many Frenchmen, especially with those in the south-west part of France, and the project has been brought forward again and again, only to be shown as thoroughly impracticable by those whose duty it has been to investigate the matter. The principal advantages held out by the advocates of the scheme are:—(1) The saving of the passage round Spain by all vessels passing to or from the Mediterranean and the northern part of the Atlantic; (2) the possibility of uniting the French naval squadron without passing under the guns of Gibraltar; (3) the commercial benefit to the neighbouring districts. The fact that the French fleet in case of a war would be able to proceed to the Mediterranean by this artificial waterway, and so escape the English guns at Gibraltar, would, in the eyes of many Frenchmen, deal a blow to our position as mistress of the sea, and lends a national enthusiasm on behalf of this scheme that serves to give it a vitality which could not otherwise exist. Some air of feasibility is given to the project by the existing Languedoc Canal, or Canal du Midi, by which barges drawing about 4½ft. can make their way from the Bay of Biscay to the Gulf of Lyons. Along this canal wine and other produce is at the present time conveyed, but the quantity thus transported is too small to hold out any hopes of any adequate proportion of income from local sources. An interesting account of this canal was given by Lord Clarence Paget, who passed through it in a steam launch drawing 4ft. 8in., in 1881. Its construction, considering the time when the works were carried out, constitutes one of the most remarkable engineering feats that have ever been accomplished. The scheme for constructing this canal was originated by Pierre Paul Riquet, who at the time he took up the project was a tax gatherer in the employ of the Government, and the possessor of a small property in the neighbourhood. Though by occupation only an exciseman, he taught himself sufficient mathematics, levelling, and surveying to enable him to lay out the line of the proposed canal, and of practical engineering to enable him afterwards to carry out the work. Having traversed the line of the canal several times on foot, examined all the sources of water supply, and had models made of the proposed locks and other works, in the year 1662, about a hundred years before Brindley began the Bridgewater Canal, he laid his plans before Colbert, the Controller-General of France, who was then actively engaged in endeavouring to open up new sources of wealth for his country. By order of King Louis XIV. a Commission was appointed to inquire into the scheme. After two months' investigation the Commissioners reported it as practicable, and a Concession was given to Riquet to carry out the works. For the purpose of raising the money Riquet was granted the sole farming of the taxes in the provinces through which the canal would pass. This source of money, however, proved utterly inadequate, and the scheme was hampered throughout the whole period of its construction by want of funds. However, Riquet, with indomitable perseverance, overcame this and the other difficulties with which he had to contend, and the canal, which was commenced in 1666, was, after fifteen years' labour, opened in 1681, six months after Riquet's death and after the loss of all his property. The total cost was £1,320,000. The length from the Garonne at Toulouse to Cette, on the shores of the Mediterranean, is 158 miles, including the passage through Lake Thau. The summit level is 600ft. above the sea, and this is overcome by 99 locks, 26 of which are on the side connecting the summit with the Garonne. These locks are 88½ft. long, 19ft. wide, with a depth of 5¼ft. on the sills. The canal is carried over rivers and under hills, by means of numerous aqueducts, bridges, and tunnels. A spur of the Montagnes Noir is passed through by a tunnel; and the aqueduct at Agen to carry the canal across the valley is 100ft. high. In some places the waterway is very tortuous, the line having to be carried in a roundabout way to avoid the land of owners who would not give their consent to its passing through their property.

The question of superseding this canal by one of sufficient size to take vessels of the largest class was first raised in 1880 by an association under the presidency of Senator Duclerc. By this scheme the ship canal was to start from the deep water basin at Bordeaux instead of from the end of the navigable part of the Garonne at Toulouse, and enter the Mediterranean near Narbonne, a distance of 254 miles, or about 100 miles longer than the existing canal, with a depth of 28ft. and a bottom width of 72ft. The summit level was to be 525ft. above the sea, to overcome which sixty-one locks were to be constructed. The estimated cost was £22,000,000. A commission of engineers which was appointed to examine this scheme reported that the cost was greatly under estimated, and that a sum of £60,000,000 would be required to carry out the work, including the necessary defence works at each end. The Board of Admiralty, which was also consulted in 1882, declared that the difficulties of navigation in the canal would be so great, and the risks of accident so numerous, that ships of the navy would never use it in times of peace; and that it was very problematical if it would be of any service during a war. The financial prospects of the scheme were also condemned by a separate Commission which examined this part of the subject.



Line of the French Canal des deux Mers

This project, thus condemned on all sides, was abandoned. In 1884, however, the idea was again brought forward by the Society for the Study of French Public Works, who applied to the Government for a concession for ninety-nine years of the right to levy tolls. The dimensions were reduced to 64½ft. width, with a depth of 25ft. The cost was put at £22,400,000, with £6,400,000 additional for the approaches. This scheme was also referred to a Commission, who reported that the cost, including interest during the ten years of construction, would not be less than £60,000,000, and that if the canal were made the advantage would not be sufficient to divert the course by Gibraltar; and that the canal would seriously interfere with the drainage of the country through which it passed.

In spite of this the Society, backed by the deputies for the region through which the canal would pass, continued to urge their claim for a concession, until at last the Government referred the matter to two Commissions consisting of engineers and nautical men. A modified scheme was submitted in which the depth was increased to 28ft. over half the width in the centre, and the number of locks reduced to thirty-eight, the estimate being altered to £29,600,000 including the approaches. The Commissions reported in 1887, declaring the project to be impracticable. The cost they put at £58,000,000 and the annual working expenses at £880,000, making an annual charge, including interest, of £3,520,000. The amount of shipping which passes Gibraltar was taken at nine million tons, and allowing the whole of this to pass through the canal, the receipts on the proposed rate of tolls would only amount to about half the annual charges. The Commission considered that the canal if constructed would only be serviceable for coasting vessels, the total tonnage of which would not justify such an enormous outlay. Notwithstanding this further adverse report, the scheme has been kept alive. Every possible means of publicity by newspaper paragraphs and pamphlets have been used; the local Councils in the department of the South-West have passed resolutions in favour of the construction of the canal. A fresh company of the Canal des Deux Mers has been formed; the public have been induced to subscribe Founders' shares, under the condition that if a concession be obtained the subscribers shall share in the profits. So much pressure has been brought to bear on the Government that M. Barthou, the Minister of Public Works, in order to enlighten the public on the matter, and out of deference to the Councils-General who have passed resolutions in its favour, advised the President of the Republic to issue another Commission. As a justification for this, he says in his report, "The promoters continued to work upon the population and on the elective bodies, and represented the Canal des Deux Mers as in the first instance an undertaking essential to the national defence, and also as a source of wealth for the country. They also appealed to the small capitalists, by making large issues of Founders' shares, promising to the subscribers a share in the profits in the event of a concession being obtained." The Commission is to consist of six of the engineers of the Ponts et Chaussées, six naval officers, three inspectors general of finance, three members of the Academy of Political Science, six shipowners and merchants, and two inspectors of agricultural hydraulics. The points on which they are to report are:—(1) Under what conditions a maritime canal between the Atlantic and Mediterranean could be constructed and worked. (2) What would be its practical utility as regards the navy, commerce, industry, and agriculture. (3) Cost of constructing such a canal. (4) To decide whether the concessions asked for should be taken into consideration."

After the reports which have been issued by previous Commissions, it seems to be a mere waste of time and money to make further investigations. Although the engineering features present no insuperable difficulties, yet, on the face of it, the scheme must be considered as financially impracticable. The advantage claimed by the promoters to the district through which the canal passes is already provided by the existing canal, which is sufficient for the conveyance of the produce of the country. As to the commercial advantages to steamers passing from the Mediterranean to the Atlantic, the tonnage of these would never be sufficient to furnish an income on such an enormous expenditure as this canal is estimated to cost, being about four times as much as that of the Manchester Ship Canal. The inducements for a large steamer to run the risk and delay of navigating a canal 254 miles long, in which it would have to pass through thirty-eight locks, and be raised and lowered over 500ft., and to pay the tolls, is very small. A steamer passing Malta and using the canal in place of going through the Straits of Gibraltar, if on her way to or from England, whence the greater part of the traffic comes, would save about 1000 miles. This saving in distance, however, is compensated by the slower rate at which a steamer would navigate the canal. On the Suez Canal, to prevent damage to the banks, the speed is restricted to 6¼ miles an hour. On the proposed canal the speed would be even less than this. It is practically impossible to drive a vessel through a waterway, the sectional area of which has so small a proportion to the midship section of a large steamer, as is proposed for this canal, except at a very low rate of speed, and as the speed diminishes the difficulties of navigation increase owing to the vessel refusing to obey her helm. The delay in getting in and out of the locks, especially with a beam wind, in addition to the time required to raise and lower the vessel, would be very great; time will also be consumed in repeatedly laying by to allow other vessels to pass. It may therefore be taken that an average speed of no more than four knots along the canal is all that can be counted on; along the Gironde double this may be allowed, but here again delay will arise waiting for the tide, as the river can only be navigated at high water, and even to ensure this very extensive dredging operations will have to be carried out. Taking the distance traversed by a vessel passing Malta and going through the canal and river to the same point in the Bay of Biscay as 1450 miles, of which 300 miles would be by river and canal and 1150 by sea, the time occupied, at four knots for the former and fifteen for the latter, would be 152 hours as against 163 hours by the present route. Taking two vessels starting from Marseilles, the saving in time by the canal would amount to about 38 hours. As regards the use of the canal for naval purposes, the smaller class of gunboats might be taken through, but the impossibility of navigating a large ironclad with a beam as great as the proposed width of the bottom of the canal, and drawing within a foot or so of the proposed depth, is apparent.

Royal Institution of Great Britain.—At the last general monthly meeting the special thanks of the members were returned for the following donations to the fund for the promotion of experimental research at low temperatures:—W. Morris Beaufort, £10; Mrs. Blomfield Moore, £200; Professor Dewar, £100; Sir Frederick Abel, Bart., £50; Edward Frankland, £21; the Right Hon. Sir John Lubbock, Bart., £20; John T. Brunner, M.P., £50; the late Thomas Hawksley (per Professor Dewar), £100; Charles Hawksley, £50; the Baroness Burdett-Coutts, £100; Sir Andrew Noble, K.C.B., £100.

Engineering Society, King's College, London.—A general meeting was held on October 26th, Professor Capper in the chair. Mr. Hayton read a paper of a very exhaustive nature on "The Use of Liquid Fuel in Boilers." He first described the nature of the fuel used, and then described the various furnaces as arranged for land and marine boilers; he also referred to the use of liquid fuel on locomotives. A discussion followed. A debate was held on November 2nd, when the relative merits of cable and electrical tramways were very freely discussed by several members. Mr. Brown led the discussion in favour of the cable system, and Mr. Welbourn advocated the electrical systems.

"The Engineer"

## THE UNION STEAMSHIP COMPANY'S MAIL STEAMSHIP NORMAN.

In our impression for Oct. 26th we illustrated the Norman, the latest addition to the fleet of the Union Steamship Company, whose vessels ply between Southampton and the Cape. On Thursday, and again on Saturday, a special train was run from Waterloo, conveying a large number of guests to see the ship. On Saturday she lay in Southampton water, and the visitors were conveyed on board by a tender. A little after noon the anchor was weighed, and the great ship proceeded under easy steam to a point nearly abreast of Cowes, when she turned and steamed back again, and took up her berth in the dock about three p.m., the visitors returning to town by the special. While the Norman was under steam an admirable luncheon was served, covers being laid for about 400. The usual patriotic and complimentary toasts were proposed and drunk with honours.

The Norman is believed to be an improvement on the Scot, than which ship the Norman is nearly 1500 tons larger, the extra displacement being obtained principally by augmenting the beam. She is 490ft. long between perpendiculars, 53ft. beam, and 37ft. 6in. deep. Her tonnage is 7392 tons. She has twin screws, and Sir Edward Harland's "drop," or hanging stern frame. The screw shafts are not carried outboard on brackets, but in-board in extensions of the tunnels worked in the hull, just as the shafts are carried in the Majestic, Teutonic, and several other vessels built by the Belfast firm. She was launched on the 19th of July.

It is not too much to say that nothing has been left undone to promote the comfort and well-being of passengers using the Norman. The state-rooms have been very carefully arranged, and the system of ventilation adopted is quite thorough and complete. The main saloon is a very beautiful apartment, and care has been taken not to overdo the ornament. The prevailing colour is that of light American or African oak—of which all the wainscotting is made—relieved with white and gold; the latter being very artistically used rather to define lines than for any other purpose. There is a great deal of wood carving in the shape of flat panel work, and this carving is uniformly excellent and artistic. The library, which also serves as a drawing-room, is fitted in much the same style, rosewood, however, being largely used for the furniture and writing desks. The smoking-room walls are surrounded by seats and couches upholstered in dark stamped Morocco leather. The walls above are hung with dark chocolate and gold embossed paper or lincrusta, and instead of the paintings which are now so often found in smoking-rooms, we find excellent engravings, most of them the best of their kind, hung on the walls. Every other part of the ship has been got up, as we have said, with the utmost regard for the comfort of the passengers. She berths 160 third-class passengers round their saloon on the main deck forward. The first and second-class are berthed amidships. The first-class saloon seats 150 passengers.

The ship is propelled by two sets of triple expansion engines, the cylinders of which are 31½in. + 52in. + 85in. × 57in. The boiler pressure is 175 lb., and there are thirty-six furnaces arranged in four stokeholds. The boilers are fired fore and aft, and there are two elliptical funnels. The speed is intended to be about seventeen knots. It has been found that on the Cape service high speeds are not asked for, and that they will not pay; but the Norman has a large reserve of power available to drive her against a head wind if needed.

We have never seen more admirable machinery. The finish of the engines is simply superlative. Their design is excellent, and the engine-room is so large that there is no cramping, and the ventilation is very good. At full speed the engines make a little over eighty revolutions per minute. On Saturday they ran at sixty, and they made no noise, nor was a drop of water to be seen on a bearing. The high-pressure rods are packed with "American" metallic packing, which seems to answer very well. The high and intermediate pressure cylinders have each one piston valve. The low-pressure cylinder has a slide valve, the weight of which is supported by a carrying piston and cylinder. The low-pressure pistons only have tail rods.

The steering gear consists of a very powerful segmental rack, the centre boss of which drops on to the rudder head. Under the rack is the tiller, which is connected with the rack by tremendous helical springs to take the jerk off the teeth. The rack gears with an endless screw, which is caused to revolve by a double vertical cylinder engine of considerable power, caused to revolve from the bridge in either direction in the usual way by a hunting screw. Hand steering gear is also provided for an emergency, the whole being shut up in a strong poop house.

Tested by any conceivable standard, the Norman is a splendid ship, and a valuable addition to the fleet of the company. In every possible way she is a credit to. her builders, Messrs. Harland and Woolf, of Belfast.

As an example of the progress of South Africa and the Union Steamship Company, it may be interesting to notice that in November, 1857, the original Norman sailed as the third ship despatched in the original mail service with Cape Town. The first Norman was a little vessel of 460 tons gross, and carried about twenty passengers and about 500 tons of cargo. She steamed at an average of seven knots, making her voyage to Cape Town in forty-two days. The new ship carries 420 passengers and 4000 tons of cargo, and will require about a fortnight to make the same voyage.

## MERSEY AND IRWELL JOINT COMMITTEE.

An important meeting of this authority was held on the 5th inst., when Sir H. Roscoe, M.P., reported on the streams in the district, and gave an approximate standard by which a comparison could be made between the existing effluent and its condition at any future time. In his statement to the committee they were informed that he had reviewed the results of 231 determinations. The oxygen consumed from permanganate of potash acting on the effluent water he considered was a most reliable method for estimating the presence and quality of the organic matter, especially as a large number of determinations might be made in a comparatively short space of time and comparisons drawn between the various effluents from sewage works. He had taken three standards, viz., one-tenth grain per gallon albumenoid ammonia; one-fourth grain oxygen per gallon three minutes' reaction; one grain oxygen per gallon four hours' reaction; twenty-three analyses were given of nineteen effluents of the sewage after treatment, and of four samples of water from the Manchester Ship Canal. Of the nineteen effluents eight came within the three standards; eleven complied with two of the standards; twelve complied with one of the standards and seven were outside all the standards. Of the four samples taken from the Ship Canal, none complied with all the three standards; one complied with two of the standards, and two complied with one of the standards.

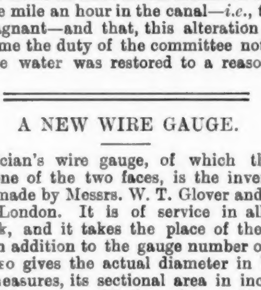
Within the area of the committee's jurisdiction it appears that there are seven county boroughs containing 1,148,700 inhabitants, and that from 43 per cent. of this population the sewage still flows untreated into the rivers. The treatment of the sewage of the remaining 57 per cent. was unsatisfactory, with the one exception of Rochdale, which has 71,400 inhabitants. Manchester was now treating the sewage from 269,800, or about one half the number of its inhabitants, by chemical precipitation alone. This was unsatisfactory. Bolton and Salford, with a combined population of over 300,000, were in a similar condition. Bury, Oldham, and Stockport, had as yet no sewage works in operation. Of the eleven non-county boroughs, with a population of nearly 300,000, Hyde having 30,000 inhabitants, was the only one in which sewage treatment was in work. The result in this case was satisfactory, With regard to the fifty-six urban sanitary authorities representing a population of 608,000, one half had no sewage works in operation; twenty-two had sewage works, generally speaking, affording satisfactory effluents. From the works of seven the effluents were unsatisfactory. The sewage from 43 per cent. of the population of six non-county boroughs flowed untreated into the rivers; 38 per cent. was satisfactorily treated, and 19 per cent. unsatisfactorily.

The Rural Sanitary Authorities have a better record. Eleven out of twelve sewage works afforded very satisfactory effluent. Notwithstanding this, it was considered that the proceedings of the committee were progressing favourably, and that those authorities whose works were unsatisfactory were being compelled by the committee to take measures to ensure satisfactory results. Extensions of time were granted to the authorities of Manchester, Farnworth, Glossop, and seven other towns. Orders were given for proceedings to be taken against Middleton for not complying with the demands of the Joint Committee, and the authorities of Knutsford and four other towns were warned of the unsatisfactory condition of the effluents in their respective districts. This shows how much time and patience is necessary to attain an end, however desirable it may be, when laxity of conduct has been tolerated for a long period.

The condition of the streams in the manufacturing districts has been a byword for a generation, and their state was disclosed by the Rivers Pollution Commissioners upwards of twenty years ago, but nothing was done to improve them. Now that the Ship Canal is made, the nuisance has become unbearable. Sir H. Roscoe states that whereas the rate of flow was previously ten miles an hour in the foulest of the rivers, it is reduced to one mile an hour in the canal—*i.e.*, the canal was practically stagnant—and that, this alteration being for the worse, it became the duty of the committee not to rest content until the water was restored to a reasonable state of purity.

## A NEW WIRE GAUGE.

The electrician's wire gauge, of which the engraving below gives one of the two faces, is the invention of Mr. Poole, and is made by Messrs. W. T. Glover and Co., of Manchester and London. It is of service in all branches of electrical work, and it takes the place of the old form of slot gauge. In addition to the gauge number of a wire, this instrument also gives the actual diameter in both English and French measures, its sectional area in inches and safe current, its resistance per 1000ft. and per mile, the number of yards of the wire to one ohm, and its weight per 1000ft.



It is thus very comprehensive, and will for all ordinary and practical purposes avoid those frequent references to electrical tables which are now unavoidable. The wire to be measured is passed through the opening in the outer ring into the space between the two circles, and moved along until it is stopped; the points of contact wire give the dimensions of the different scales. The instrument being flat is of a very convenient form for the pocket, is nickel-plated, and is issued in a neat leather case.

## SOME PECULIARITIES OF OXIDISED LINSEED OIL.

Last Monday night, at a meeting of the London section of the Society of Chemical Industry, Mr. B. E. R. Newlands in the chair, Mr. F. W. Reid set forth some treacherous characteristics of oxidised linseed oil when employed in various arts and industries.

The speaker said that nearly all the linseed oil utilised in this country is employed in the oxidised form; much of it is then used in the manufacture of linoleum and for mixing with india-rubber. There are two large and several small methods of oxidising it; the one large one is the application of heat, up sometimes to a maximum of 500 deg. Fah., and occasionally expediting the action by blowing air through it; the product is a dark-coloured viscid mass; by the other larger method the oil is boiled with litharge, then allowed to flow over a thin fabric, after which it is suspended in a shed at a temperature of 80 deg. Fah. to 100 deg. Fah.; the fabric is coated and dried thus several times in succession. These lengths of dried oil are passed between rollers; the substance then forms an amber-coloured mass of low tensile strength and considerable elasticity; it is heavier than water. When the doors of the drying sheds are first opened in the morning no mortal can enter them, the air being so full of acroleine; if any use can be made of this waste product, here is a plentiful supply. In the linoleum industry the dried oil is then ground and heated with cowrie gum and other resin until it forms what in the trade is known as "cement."

He had tried experiments with oxidised oil extending over many years, and had observed that the boiled oil goes on oxidising after it has been applied to its various uses. In two years it becomes sticky, in three years it begins to run, in five years it is partly liquefied, is easily soluble in alcohol and partly soluble in water, and finally it becomes a semi-fluid substance containing vegetable acids. These changes are more rapid when paints in which it is used as a vehicle are exposed to the weather, hence such coats of paint have to be renewed at short intervals. For the same reason it affects the permanency of oil paintings, and when it becomes acid attacks the basic pigments; moreover, the floating dirt in the air settles upon the sticky surface and is held there. The brown stains in old books on the pages opposite heavy engravings are due to this sticky product of decomposition, as he had found by analysis. The deteriorated oil causes old note books bound with American cloth and laid aside for a time, to stick together. When india-rubber is weighted with oxidised linseed oil it becomes useless in a very short time; this fault is sometimes found in the flexible tubing used in laboratories. It seems to be a peculiarity of nearly all flexible substances having somewhat the physical properties of india-rubber that they should oxidise rapidly. He knew but of one exception, and that was the scarce jelly-like mineral, elaterite, of which he exhibited a piece which had been exposed to the air for thirteen years and had not altered at all. Linoleum, with so much oxidised oil in it, lasted longer than might be expected, but then it must be remembered that therein the superoxidised substance was incorporated with 40 per cent. of powdered cork; out of any piece of linoleum several years old, the products of decomposition of which he had spoken could be extracted by alcohol. He regretted that eminent artists of to-day are using linseed oil in their work. Nut oil and poppy oil are as bad; they oxidise more slowly, but finally liquefy.

Professor T. E. Thorpe, the president of the Society, stated that once a blanket manufacturer near Huddersfield found his blankets going into holes soon after bleaching with fumes of sulphur; this was discovered by the speaker to be due to oil from the bearings of the centrifugal machine splashing on to the blankets, and sulphurous acid in contact with oil oxidised into sulphuric acid at a surprisingly rapid rate; the latter acid caused the holes.

Mr. Christie said that a peculiar oil and varnish made from petroleum is about to be brought into use, and he hoped soon to be able to lay the details before the Society. Painting a busy London restaurant is a serious thing for the proprietor, because meanwhile his customers disappear; one of these restaurants had been painted one night and varnished the next night with these substances derived from petroleum. There was no smell, and the customers knew nothing about it, except that they saw that the restaurant had been renovated.

Mr. Cresswell was of opinion that house paints without lead oxide in them to form a soap with the oil are usually of little durability. Shortly afterwards the proceedings closed.

## YORK SANITARY SCHEMES.

The city of York, which in point of rank, though not in commercial importance, is the second city in the kingdom, will soon have in operation an admirable scheme of sewerage and sewage disposal, designed by Mr. J. Mansergh, C.E., Westminster. The new scheme comprises about eight miles of sewers. The sewage pumping and precipitation works, plant, and machinery have ample present capacity, and can be readily enlarged to supply the needs of double the present population. There is a relay of steam boilers, with machine stokers, engines, machinery, and plant. The pumping station is situated at Fulford, about two miles southward from the Guildhall. The precipitation station is on the Naburn-road, about a mile further south. Both stations are on the easterly bank of the river Ouse. The buildings at both stations are of red brickwork, with Pateley Bridge, Yorkshire, sandstone dressings. Bramley Fall stone is used for plinths, as well as for engine beds, which are laid upon large blocks of cement concrete. The grading of the ground around the buildings is raised above the flood level of October, 1892. The buildings have slated roofs. Vertical triple expansion engines of 280-horse power are in course of operation at the pumping station where the lift of the sewage is 32ft. Dead animals and other large objects are here screened out of the sewage before it is passed onward to the precipitation station. Centrifugal pumping engines are in place to deal with sudden storm and flood waters.

The precipitation tanks, as well as the mixing, baffling and conveying channels, are constructed of cement concrete, and all are faced, coped, and paved with impervious brickwork. The bottoms have a gradient of one in eighty. Down along the centre of the bottom of the tanks a channel of steeper gradient is formed for the sludge. The engines, boilers, and machinery are not yet in place at this station, but the buildings are ready to receive them. The chemical treatment of the sewage is to consist of prepared lime and alum, which are passed into the sewage at proper points before it is passed into the precipitation tanks. The clarified effluent passes over an end weir of each tank, and is thence conducted to the river. Each tank is supplied with a swivelled sediment separator. The tanks can be used separately or in convenient combinations. The sludge is conducted to elevated iron tanks, from which it is passed to pressing machinery supplied by a Nottingham firm. The sediment is thus reduced to a convenient form to sell for manuring purposes. The engines, boilers, and machinery are not yet in place at the precipitation station, but the buildings are ready to receive them. This scheme is expected to be in operation early in January next. A six-cell refuse destructor is also contemplated.

Mr. I. McKie, C.E., is the resident engineer, Mr. Alfred Creer, A.M.I.C.E., is the city engineer and surveyor of York

Search for Coal in East Anglia: Commencement of Operations.—A meeting of the directors of the Eastern Counties Coal Boring Association was held at Ipswich on Tuesday, when there were present Mr. R. C. Rapier (chairman), Captain Pretyman, Colonel Barnardiston, Mr. G. Calver Mason, Mr. Reuben Hunt, and Mr. T. R. Elkington. The meeting was held for the purpose of going through the tenders for carrying out the boring, and after consideration it was decided to accept that of the Vivian's Boring and Exploration Company, of Whitehaven, and the contractors have to commence operations within the next few weeks. The Vivian's Company has an excellent reputation, and was recently successful in discovering coal at Haxey, in Lincolnshire, and just now has on hand some other heavy contracts for deep boring. The first bore will be made upon the estate of Mr. W. J. Graham, at Stutton, on the banks of the river Stour.

## RAILWAY MATTERS.

The railway from Tunis to Biserta was opened on the 2nd inst. with great rejoicings.

It is stated that the North-Eastern Railway Company has purchased land at Blyth for the purpose of erecting engine works.

We have received from Mr. F. Snary, of Castle-street, Bristol, an excellent photograph of the Great Western express engine Achilles. This is of the same class as the Agamemnon, illustrated in our last impression.

There are 15,812 miles of Prussian State railways, 62 miles of narrow gauge lines serving as common carriers and feeder lines. There are 124 miles not used for public traffic; 1118 miles of the Prussian State lines are outside Prussia.

The Cape railway officials visiting Pretoria have made amicable arrangements for a joint traffic. When the Natal line opens there will, the *Times* correspondent at Pretoria says, be a further conference between the heads of the Cape, Netherlands, and Natal Railways finally to settle the tariff.

The large falling off in North-Eastern Railway traffic receipts, while it shows that business is not as active as it was in the autumn of last year, does not unfavourably influence the market, because last year the traffic was abnormally increased by the miners' strike in the Midlands, which caused a much larger demand for the products of this district, especially the coal. Last week the mineral receipts were £12,062 short of those of the corresponding week last year.

It is proposed to "split" the ordinary stock of the Rhymney Railway, and thus follow the tactics of the Taff, which have answered very well. Circulars were issued in September to the shareholders for their opinion, and I hear that out of 150 replies only ten dissented from the project, so it may be expected to take place at an early date. It is thought that powers will be applied for in the next session, and, these granted, the Rhymney will be in as good a position as the Taff and the Barry, which obtained powers lately.

The commission, now sitting at St. Petersburg, to decide which of the many northern railway projects should be carried into execution, has apparently resolved on the continuation to Archangel of the existing Moscow-Vologda line. This proposal by no means meets with general approval among the merchants who would much prefer the project pressingly urged on the authorities by the new governor, viz., a railway from Kazan on the Volga to Kotlass at the junction of the Vychegda and Northern Dwina.

The Port Talbot Railway and Docks directorate will very probably, so thinks a local authority, be constituted as follows: Lord Dunraven chairman, Col. Wright, Messrs. S. H. Byass, E. Knox, Thomas Watson, and Mr. Llewellen Wood. This would imply vigour and ability of no ordinary character. Both Port Talbot and Llanelly have a promising future. The electric lighting of Newport is expected to be in full operation in January, and to some private consumers in December. The latter feature, so far, is not a promising one in the case of Cardiff.

Commenting on the recent granting of a franchise for a 78-mile narrow-gauge railway, to be built in the Government of Wilna, in Russia, the *Strassenbahn*, a German street railway journal, takes occasion to point out that the first narrow-gauge railway in Russia was opened on September 14th, 1892, and has been operated successfully ever since. It is the St. Petersburg-Ochta-Irinowka line, better known simply as the Irinowka road, and was built during the summer months of 1891 and 1892. The total length of the line is 33½ versts—about 22 miles—and the gauge is 750 mm., or about 30in. The locomotives in use are four-wheeled tender engines, rated at from 30 to 40-horse power. The entire road was built and equipped by the German firm of Arthur Koppel, of Berlin.

On Tuesday, the London County Council resolved, by 103 votes to 4, to serve a notice on the London Tramways Company, requiring it to sell to the Council the portion of its undertaking authorised by the Extension Order of 1873, consisting of about 2¼ miles from Kennington Park-road to Old Kent-road. The proposal is to purchase about 2¼ miles of tramway extending from Kennington Park-road, along Newington-causeway, Blackman-street, Borough, Great Dover-street to Old Kent-road. It is only a small section of the system belonging to the company, the whole measuring about 23⅝ miles, but it is a very important section, as two branches spread out from it, one going to Brixton and Streatham, and the other to Balham and Tooting. The remainder will fall in about four years hence.

In a report to the Board of Trade on the collision that occurred on the 31st August at Cambridge Station on the Great Eastern Railway, Major Yorke says:—"This collision, which presents all the features usual in cases of this kind, was clearly due to the fact that driver Downs entered the station at too high a rate of speed, and thereby broke the rule which enjoins that trains shall not enter dead-end bays at a greater than hand-brake speed. In conclusion, I would draw attention to the following extracts from my report of 22nd March, 1894, on the stop-block collision which occurred on the 26th February at the London and North-Western Railway's London-road Station at Manchester: 'It is satisfactory to note that the London and North-Western Railway Company do not permit the continuous brake to be used in stopping trains in terminal stations, except in cases of emergency. The instructions to guards in the Appendix to the Working Time-book as to the mode of entering terminal stations are as follows, viz.: "Guards must in all cases use their hand-brakes to assist in stopping trains on approaching terminal stations, bay sidings, or principal stations, and must not rely on the drivers pulling up trains by means of the vacuum brake."'"

Writing on the nationalisation of our railways, the *Railway News* says there is no use in blinking the fact; nationalisation by inches is an accurate and moderate phrase for describing the relations subsisting between the British State and the British railways. It is certain there has been no slackening in the collectivist policy from the date of the Royal Commission Report of 1867, which was dead against it, to the present; rather, the impetus gained from previous efforts has increased the speed. It is time, therefore, that railway shareholders should seriously consider the result to themselves of further developments along the same line in the future. It may be said that we are exaggerating; that no scheme for the State acquisition of railways is within the range of practical politics. The writer then refers to the gradually increasing interference by the State with the construction and working of our railways, and concludes:—Obviously, however, this form of "progress" has its limits. Public interference cannot extend indefinitely for the simple reason that it will exhaust its material. A certain amount more of "railway legislation," and there will be no railway of a privately owned and managed kind to legislate upon. The independent company will be metamorphosed into a department of the Board of Trade. No revolutionary change is necessary to effect this purpose, a steady continuance along the present lines is sufficient. Without our realising it our railway industry is slowly but surely being nationalised. And not a penny piece of compensation is being paid for property injured, and privileges curtailed. If we continue to drift along the path which we have hitherto folowed it will only be a question of time for the most magnificent heritage of modern industrial society to slip completely from the grasp of its owners into that of a democratic state. And its present holders will not be paid with even thanks.

## NOTES AND MEMORANDA.

The electrical conductivity of water in as high a state of purity as possible has been determined by Messrs. Kohlrausch and Heydweiller, and that of pure water calculated from the results. The water was distilled and examined in a vacuum, as contact with air rapidly raises the conductivity, which, in some experiments, rose from 0·11 to 0·14 in four minutes, reaching 0·58 in two hours. The results at various temperatures of the purest water obtainable were at 0 deg., 0·014; at 18 deg., 0·040; at 25 deg., 0·058; at 34 deg., 0·089; at 50 deg., 0·176.

In calling attention to the advantages of the inverted arc lamp, the *Ziet. fuer Elek.* says a 10 ampère 45·5 volt lamp gives a maximum of 2070, and a mean spherical intensity of 750-candle power, of which 640 are below the horizontal plane through the arc; by means of the inverted arc and a reflector almost the whole of this spherical intensity can be produced below the lamp, and it will be then equal to about 46 incandescent lamps of 16-candle power, which at 50 watts require 2300, while the arc lamp requires only 455, representing a saving of about 400 per cent.

In a correspondence on a new mode of decorating church walls, Mr. A. W. Keim draws attention to a process of his own called "Mineralmalerei," which consists essentially in the use of siliceous clay and sulphate of baryta, both on the painting-ground and in the colours. By the addition of carbonate of baryta the sulphuric acid gas found in the atmosphere of our large towns, and the sulphurous acid gas, which is very injurious to fresco paintings and to limestone, are neutralised and even become a means of hardening the paintings executed according to this process.

In a paper on the magnetic lag in iron cores due to periodic alternating magnetising forces, Mr. Dechant shows that two periodical alternating magnetising forces of a certain phase difference, when acting on different parts of an iron bar, develope magnetic waves of varying amplitude, which travel along the iron but with relatively small velocity; the latter is found when the distance between the places where the forces act are divided by the phase difference; he proves this experimentally. He also shows that the diminution in the intensity of magnetisation along the bar is an essential condition for the existence of this lag.

Cellulose in a dense form, having the appearance of ebonite, and capable of taking a high polish, can be prepared by treating cellulose with a 15 per cent. solution of sodium hydrate, and "mercerising" it. The "mercerised" cellulose is then exposed to the vapour of carbon bisulphide, which forms a soluble compound with it. On dissolving this in water, the carbon bisulphide and sodic hydrate are gradually given up, cellulose being precipitated. If some of the solution is spread on glass, a transparent film of cellulose can be obtained. Cellulose can also be deposited from the same solution on woven materials on paper, producing a permanent stiffening or sizing. The solution also forms a substitute for glue, of great strength, and insoluble in water when set. The material can also be obtained in continuous sheets or films.

The Welsbach incandescent gas burner mantles are made of fine cotton netting, carefully washed, to render it pure. The clean cotton mantle is soaked in a complex fluid containing amongst other things a chloride of zirconium. They are then dried, and after undergoing one or two intermediate operations, are strongly heated in a Bunsen flame, by which the cotton is burnt away. The skins or films which are left behind consist of the substances dissolved in the fluid just mentioned, and are so fragile as to crumble to dust at a touch. To make them sufficiently strong to bear handling they are dipped in collodion, and after being trimmed with scissors, wetted with methylated spirit, are packed in boxes for distribution. The light obtained as a result of this treatment is comparatively rich in actinic rays, so that it is quite possible to take photographs by means of it.

On Monday evening the Council of The Royal Agricultural Society entertained the Duke of Westminster, Sir Walter Gilbey, and others at dinner at Hanover-square, the new premises, into possession of which the Society has entered. There followed a conversazione, at which upwards of 600 guests were present. The mansion, now the property of the Society, was the residence of Lord Harewood, and was built by Richard Adams, one of the famous brothers after whom the Adelphi took its name. All the rooms are of handsome proportions; are decorated in the Adams style; the walls are hung with the paintings belonging to the Society—portraits of famous agriculturists, and pictures of famous animals. In the several rooms of the house were exhibits of special interest to agriculturists, specimens of diseased plants, insect pests, fertilisers and feeding stuffs, medals, the Royal Charter of the Society, and short lectures were given in the council chamber, with lantern demonstrations. The new occupants and guests greatly admired the fine old house.

At the date of the last decennial census in 1891 Canada had a population of 4,833,239 persons, of whom 2,466,573 were males, and 2,366,666 females. The populations of the several provinces were as follows:—Ontario, 2,114,321; Quebec, 1,488,535; Nova Scotia, 450,396; New Brunswick, 321,263; Manitoba, 152,500; British Columbia, 98,173; Prince Edward Island, 109,078; the Territories, 98,967. In 1893 there were in all 75,741 industrial establishments, having an invested capital of £70,905,252, employing 370,104 hands, distributing to wage-earners £20,131,300 a year, and producing articles the total value of which was £95,236,671. The railway mileage of the Dominion open for traffic was 15,020; the working expenses of these railways amounted to £7,323,207, and the earnings to £10,408,479. The public debt of the Dominion was at the close of last year £60,010,905, against which there were assets amounting to £11,674,697, leaving a net indebtedness of £48,336,208. The Government expenditure on railways amounted to £268,585, that on canals to £460,580, and on other public works to £276,674.

According to a paper on "The Prevention of Scale in Boilers," by J. Walter, if the water is fed into the boiler, together with small quantities of a solution of sodium carbonate, the deposit of scale is not prevented, but is localised more upon those parts which are nearest to the opening of the feed-water pipe in the boiler. The probable cause of this is the difference between the temperature of the water in the boiler and that of the feed-water. If, therefore, the temperature of the feed-water were raised to the temperature of the boiler before coming in contact with the latter, all incrusting matters would be precipitated beforehand and no scale could form upon the boiler plates. To effect this result a 6in. tube is placed on low supports along the centre of the boiler at a distance of about 6in. from the bottom. The front end of this tube is open, the back end closed with a blank flange. From the back end rises a vertical pipe reaching above the level of the water in the boiler and loosely encasing the feed-water pipe. The water fed into the boiler does not therefore mix immediately with the water in the boiler, but passes through the narrow vertical tube, and subsequently through the wider horizontal tube. During this passage its temperature rises to that of the boiler, and the incrusting matter is precipitated within the horizontal tube, no subsequent formation of scale upon the boiler plates taking place. Any of this precipitate washed out of the tube will be found to form a layer of fine sludge on the bottom of the boiler or a granular coating on the sides, which is easily removed by a brush. The greater part of the precipitated incrusting matter will be found in the horizontal pipe, which after being cleaned is reinserted. The *Journal* of the Society of Chemical Industry says this arrangement was found to form a reliable means of preventing the formation of hard scale.

## MISCELLANEA.

Mr. Alexander Siemens, M. Inst. C.E., of Woolwich, has accepted the Presidency of the Institution of Junior Engineers, formerly the Junior Engineering Society, for Session 1894-5, in succession to Mr. J. Wolfe Barry, C.B., V.P. Inst. C.E., and will deliver his Presidential Address on Friday evening, 16th inst., at the Westminster Palace Hotel.

Mons. George T. Rickard, director of the Société Cockerill's shipbuilding establishments at Hoboken, Antwerp, has been promoted to the grade of Officer of the Order of Leopold, in consideration of his services in promoting Belgian industry. Mons. Edmond Crets, the engineer at the shipbuilding works, is nominated Chevalier of the Order of Leopold.

The Board of Agriculture desire to acquaint intending exhibitors at the forthcoming Agricultural Exhibition at Montevideo, to which attention was directed by a notice issued on the 30th ult., that copies of the regulations and forms of entry can now be obtained on application, either personally or by letter, from the Secretary to the Board, 4, Whitehall-place, London, S.W.

The Staveley Coal and Iron Company made the iron pipes, &c., for the Thirlmere water supply of the Manchester Corporation. The work, which included 30,000 to 40,000 tons, was in progress for some seven years. The Staveley Company, which has recently concluded contracts for the waterworks of Liverpool and Leeds, is now engaged upon similar work for Alexandria and South Africa.

On Monday evening, November 5th, the members of the Hull and District Institution of Engineers and Naval Architects assembled at the Institute rooms, Bond-street, to hear Mr. Alfred H. Gibbings—Borough Electrical Engineer—read his promised paper on "Electricity on Board Ship, and its Application as Motive Power for Auxiliary Machinery," the president, Mr. J. H. Pearson, being in the chair.

It is proposed to establish an Association of English Cement Manufacturers for the purpose of dealing with and, if possible, of putting a stop to the adulteration of English Portland cement—a practice exceedingly detrimental to the best interests of the cement trade. Messrs. Renshaw, Kekewich, and Smith, solicitors, of 2, Suffolk-lane, E.C., are prepared to receive names of manufacturers willing to attend a meeting presently to be convened.

The Institution of Civil Engineers is building a new house, but it will not be ready until a year hence. In the meantime arrangements have been made by which the old meeting-room can be reached from a temporary entrance in Great George-street. The members will assemble next Tuesday, the 13th inst., to hear the inaugural address of the new president, Sir Robert Rawlinson, K.C.B., and to witness the ceremony of presenting the prizes and premiums awarded for papers read last session.

A well supported scheme for constructing a large embankment in the Bay of Fundy, for the purpose of reclaiming land, is under consideration, and a well-known English engineer has been in Nova Scotia to report upon it. Considering what a drug land is at the present time, it does not on the face of it seem a very opportune time to increase the quantity already in existence, but the people out there who have this matter in hand seem to see their way to make it a profitable undertaking if they can raise the capital.

On Tuesday, the 30th ult., the Sandwich Mayor and Corporation assembled at the pumping station, Woodnesborough, and took over the waterworks from the contractor. The party consisted of the Mayor, Major Mate, Mr. Courtney, M. Inst., C.E., representing the engineers, Mr. Brown, A.M. Inst., C.E., and others. The boilers, engines, and pumps are in duplicate, the pumps being capable of delivering 15,000 gallons of water per hour to the reservoir on Beacon Hill. They have been supplied by Messrs. Warner and Son, of Walton-on-the-Naze. Mr. H. Roberts, of West Bromwich, was contractor for the works, which have been designed and superintended by Messrs. Easton, Anderson, and Goolden, the engineers.

The Pittsburgh—Lake Erie Ship Canal project has now reached a stage when it will be possible for outsiders to gain some idea of how the proposed waterway is regarded by the business men of the Pittsburgh district. An examination of several routes has been made by an engineering committee of the Ship Canal Provisional Committee, the Pittsburgh organisation intrusted with promoting the project, and now the public is invited to subscribe to a guarantee fund of £20,000 to make the necessary detailed preliminary and final surveys, and to pay for other expenses in placing the project on a business footing. The subscribers are not to pay in the amount of their subscriptions at once, but calls will be made from time to time as funds are needed. The *Engineering Record* says the cost of the canal is estimated at about £5,200,000.

The annual meeting of the South Lancashire and Cheshire Coalowners' Association was held in Manchester on Tuesday, and Mr. W. Johnson, of the Abram Collieries, near Wigan, was unanimously re-elected president for the ensuing year. This association deals chiefly with Parliamentary and railway matters affecting the coal trade, and does not interfere with questions affecting either wages or prices; but the general secretary, Mr. Thomas Ratcliffe Ellis, who is also the secretary for the Coalowners' Defence Association, informed me that matters were going on very quietly and satisfactorily between the coalowners and the men, and that with reference to the proposal to form a Conciliation Board, which was not agreed to by the coalowners at a recent conference, there was no intention, at any rate at present, of making any further move in the matter.

The 4000 tons forging press, with the power travelling cranes, each of 150 tons, and the plant generally at the Atlas Works of Messrs. Sir J. Brown and Co. were made by Messrs. Tannett, Walker, and Co. The pumping engines for working the press are, we believe, as large as any in existence; they have steam cylinders 60in. in diameter by 54in. stroke. The press is of great capacity, and this will be easily appreciated when we say that the distance from centre to centre of the columns is 18ft. This press and engines were at the time they were made a long way in advance of anything that had been done at that period, and we may mention that the firm have constructed similar presses for Herr Fried Krupp, Essen; the Baltic Iron, Shipbuilding, and Engineering Company, St. Petersburg; Schneider and Co., Le Creusot; Monk Bridge Iron and Steel Company, Leeds; the Terni Works, Italy; the Witkowitz Works, Austria; the Compagnie Anonyme des Forges de Chatillon and Commentry, Montlucon; the Spanish Government, and many others.

Sheffield will be largely represented at the cutting of the first sod of the Manchester, Sheffield, and Lincolnshire new line to London next Tuesday. The ceremony is to be performed by Lady Wharncliffe, the wife of the chairman of the line. The Countess will be presented on the occasion with a large and massive casket, which has just been completed by Messrs. Mappin and Webb, of Sheffield. It is in sterling silver, and weighs 160 ounces. The style is Palladian, or, as it is more generally called now-a-days, "Queen Anne." The casket, which displays some most elaborate and beautiful work, exhibits the arms of the Earl and Countess of Wharncliffe, with supporters and motto, and the four crests of the family. On the reverse is the ribbon with legends and shields of the five cities and towns, with intervening national embelms, which form the device of the Manchester, Sheffield, and Lincolnshire Railway Company. The centre circles on the obverse and reverse display raised monograms—that of the Earl and Countess on one side, and that of the Manchester, Sheffield, and Lincolnshire Company on the other.

# LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

## THE THEORY OF THE STEAM ENGINE.

Sir,—Your correspondent, "Ttaw," asks if Professor Smith and I are authorities on such matters. Now, I thought that science discarded authority. For my part, I claim no authority. I always give a reason for what I say, and I think nothing I said in my last letter can be denied. Nay, I do not suppose that any writer on thermodynamics would try to deny it. All that I accuse writers on this subject—myself included—of is that they have not emphasised sufficiently the fact that Carnot did not intend his cycle to be aimed at in practice, but merely used it as a mathematical mode of investigation of thermodynamic principles.

I think that Professor Smith is quite right in what he says when he denies that this cycle has a superior claim to other cycles in the matter of reversibility, and—though, not being a practical engineer, I am not so sure of this—in the matter of efficiency. I see it stated with great emphasis in many books that the reversibility and consequent perfection of Carnot's cycle depends on the engine receiving all the heat it gets at one temperature, and giving out all that it does give out at another temperature—a lower temperature. Now, if those who are interested in this subject will study pages 107-9 of my treatise on thermodynamics, they will find it demonstrated that, if the cycle of Stirling's air engine could be executed without waste, it would be as perfect as Carnot's cycle gone through with equal perfection. Now, the cycle of Stirling's air engine is a ($t$, $v$) cycle with a regenerator, in which cycle the heat is not all taken in at one temperature, nor all given out at another temperature. This disproves the said teaching.

Again, in the complex cycle described by Clausius at §8 of his treatise, $Q_1$ units of heat are received by an engine at temperature $T_1$, $Q_2$ units are received at temperature $T_2$, and $q_3 + q^1_3$ units are given out at temperature $T_3$. The work which would be done by the engine would be

$$W = Q_1 \cdot \frac{T_1 - T_3}{T_1} + Q_2 \cdot \frac{T_2 - T_3}{T_2}$$

And its efficiency would be

$$\frac{W}{Q_1 + Q_2} = \frac{Q_1}{Q_1 + Q_2} \; \frac{T_1 - T_3}{T_1} + \frac{Q_2}{Q_1 + Q_2} \; \frac{T_2 - T_3}{T_2}$$
$$= 1 - \frac{T_3}{Q_1 + Q_2} \left(\frac{Q_1}{T_1} + \frac{Q_2}{T_2}\right)$$

Now if all the $Q_1 + Q_2$ units of heat received by the engine were to be received at one temperature it must be at temperature $T_2$—at the very highest—because while $Q_1$ could easily be let down from temperature $T_1$ to $T_2$, $Q_2$ could not be got up to $T_1$ without compulsion. If, then, the $Q_1 + Q_2$ units are all received at temperature $T_2$ the efficiency would be

$$\frac{W}{Q_1 + Q_2} = 1 - \frac{T_3}{T_2}$$

which is less than (1), which disproves the teaching spoken of.

26, Smith-street, Hullhead, Glasgow, November 5th.　　Peter Alexander.

---

Sir,—I have been much surprised to find that in the discussion on this subject no direct reference has been made to the results obtained by the discussion just concluded upon thermodynamic matters, and look with amused curiosity for the reply which may possibly be made to "Ttaw's" questions. It seems to me that fashionable *fin de siècle* thermodynamicians have altogether overlooked the fact that there are two classes of heat engines, viz., those in which the operative substance is itself the sole source of heat—for example, gas and oil engines—and those where we have to deal only with the heat added to the operative substance—for example, steam and hot air engines. In the case of the former, if the heat at first possessed by the operative substance is equal to the product of T, the absolute temperature produced by explosion multiplied by a constant number of foot-pounds, and the heat possessed by the operative substance at the end of the stroke on the eve of the opening of the exhaust is equal to $t$, its then absolute temperature multiplied by the same constant number of foot-pounds, the coefficient of efficiency must be less than $\frac{T-t}{T}$, because the whole of the heat corresponding to the fall in temperature, $T - t$, has not been expended in doing work upon the piston. The meaning of the ratio $\frac{T-t}{T}$ is, however, in this case *toto cœlo* distinct from the meaning of the ratio $\frac{T-t}{T}$ deduced from the Carnot cycle. In the case of the steam engine, we have to divide the whole operation into two stages, viz., the stage in which the heat is added to the operative substance and the stage in which it is utilised. If the value of J is independent of the temperature, and T $t_1$ represent the indicated temperatures of the steam and the feed-water, and N the number of thermal units of so-called latent heat, the heat added to each pound of the operative substance is equal to $(T - t_1 + N)$ J, and this, divided by the total heat expended per pound of water converted into steam, is the coefficient of efficiency of the boiler, which we may denote by the letter B. If $Sv$, the specific heat of steam, is independent of the temperature, and $t_2$ is the indicated temperature of the steam on the eve of the opening of the exhaust port, by which the steam is admitted into either the air or the condenser, and Q T represents the diminution of the so-called latent heat of steam from the instant of its generation to the instant of exhaust, the heat lost by each pound of steam is equal to $\left\{ Sv(T - t_2) + Q \right\}$ J. Since the whole of this has not been expended in doing work upon the piston, the coefficient of efficiency of the engine must be less than

$$\frac{Sv\,(T - t_2) + Q}{T - t_1 + N} = E,$$

the maximum theoretical coefficient. The actual coefficient of the efficiency of the whole installation must therefore be less than the product E B. In the case of the indicated diagram of a condensing engine, the work calculated from the area below the atmospheric line represents the saving effected by diminishing the back pressure, and has nothing to do with the value of E. The heat utilised by using the water from the condenser increases the efficiency of the whole installation, but this also has nothing to do with the value of E B.

Some authorities affirm that the value of Q J cannot exceed the value of $P\,(V - v)$, the work done by the instantaneous expansion, where V and $v$ represent respectively the volume of 1 lb. of steam and 1 lb. of water at the pressure P, and that the difference between the value of the whole of the so-called latent heat and of $P\,(V - v)$ can only be converted into sensible heat by condensing the steam. Now, in accordance with the theory of the convertibility of heat and work this difference can only be represented by molecular *vis viva*, which must be converted into heat by molecular friction. The greater the pressure, the more rapid the rate of conversion. This fact, and the greater length of time occupied in passing through the cylinders of the compound engine, constitute the chief causes of the greater efficiency obtained by the use of high-pressure steam and compound engines. The increase in the value of E caused by the increase in the value of T is utterly inadequate to account for the difference between the efficiency of a high-pressure compound condensing engine and a low-pressure single-cylinder condensing engine.

If we adopt the lowest admitted value of J, viz., 772 foot-pounds, the value of $P\,(V - v)$ per pound of steam is less than 80 J for steam at atmospheric pressure, and less than 86 J for steam at 150 lb. pressure. We may, therefore, for the purpose of this discussion assume that it is equal to 80 J for all pressures. If equal increments of volume correspond with equal increments of heat the value of N is about 965, and if the coefficient of expansion per increment of unit of heat is constant to about 1080 for the temperature of 212 deg. So far as this discussion is concerned, we may put $N = 1000$ for all temperatures. The coefficient of efficiency of the boilers may be taken to be equal to ·5. The heat possessed by 1 lb. of steam coal is said to be equal to about 16,000 thermal units, if $J = 772$ foot-pounds; this is equivalent to 6·2-horse power per pound of coal per hour. With the value $B = ·5$ therefore, the heat added to the water per pound of coal burnt per hour is equivalent to 3·1-horse power.

In the case of quick speed single-cylinder engines placed close to the boiler, we may assume that the value of Q J does not appreciably exceed the value $P\,(V - v)$. For the initial pressure of 60 lb. indicated the Boyle and Marriotte temperature of the steam is about 307 deg. Fah. In the case of non-condensing engines the final absolute pressure can hardly be less than 18 lb. absolute or $t_2$ not less than 220 deg. Fah. The value of $t_1$ may be taken to be equal to 60 deg. Fah. If, then, equal increments of volume correspond with equal increments of heat, and we put $S_v = ·3$, the maximum value of E is ·085 on the data stated above. If the coefficient of expansion per increment of unit of heat is constant, it will be somewhat less. The maximum effective work, therefore, which can be got out of the consumption of one pound of coal per hour is equal to 3·1 × ·085-horse power = ·26-horse power. In order to arrive at the maximum attainable indicated horse-power, we have to deduct from this the work done in overcoming the back pressure of the atmosphere. The volume of one pound of steam at 17 lb. pressure absolute may be taken to be equal to 23 cubic feet, and the number of pounds of water evaporated by one pound of coal is on the above data equal to $\frac{8000}{1247} = 6\ 4$ lb., so that the horse-power required to overcome the resistance of the back pressure is equal to

$$\frac{23 \times 14{\cdot}7 \times 144 \times 6{\cdot}4}{33{,}000 \times 60} \text{ H P.} = {\cdot}16 \text{ H.P.}$$

The maximum theoretical indicated horse-power therefore attainable per pound of fuel per hour is ·1 indicated horse-power, which corresponds with 10 lb. per hour per indicated horse-power. If we put $S_v = 1$, the maximum value of E is ·134 and the maximum attainable work which can be got per pound of coal per hour is equal to 3·1 × ·134-horse-power = ·42-horse power. The maximum indicated horse-power corresponding to this is ·26 indicated horse-power, which is equivalent to nearly 4 lb. per hour per indicated horse-power.

In actual practice with single cylinder non-condensing engines, the fuel consumption in the best installations does not exceed 6 lb. of coal per hour per indicated horse-power. In the case of condensing engines, when the condensed water is used for the feed-water without passing it through a regenerator, we may put $t_1 = 100$ deg. Fah. The final pressure cannot be put at less than 7 lb. absolute, for which $t_2 = 177$ deg. Fah. and, if $S_v = ·3$, we have $E = ·1$, and the maximum attainable work per pound of coal per hour is equal to ·31-horse power. The volume of 1 lb. of steam at 7 lb. pressure is equal to about 53 cubic feet; and if we assume the back pressure to be equal to 2 lb, the work done in overcoming back pressure is equal to

$$\frac{53 \times 2 \times 144 \times 6\ 6}{33{,}000 \times 60} \text{ H.P.} = {\cdot}05 \text{ H.P.},$$

since the water evaporated by 1 lb. of coal is equal to $\frac{8000}{1207} = 6\text{-}6$ lb. The maximum attainable indicated horse-power is therefore ·26 indicated horse-power, which corresponds with a fuel consumption of about 4 lb. per hour per indicated horse-power. If we put $S_v = 1$, we get $E = ·17$, and the maximum attainable work per pound of coal per hour ·53-horse power; so the maximum indicated horse-power attainable is ·46 indicated horse-power, which corresponds with 2·2 lb. of coal per hour per indicated horse-power. The actual consumption per hour per indicated horse-power in the best installations is about 3 lb. We cannot but regard these results as giving irrefragable proof that the specific heat of steam is equal to the specific heat of water.

In the case of compound engines, we may take the initial pressure to be 150 lb. to the square inch, which corresponds with the Boyle and Marriotte temperature of about 366 deg. Fah. As in the case of the single-cylinder condensing engine, we may put $t_2 = 177$ deg. Fah., and with the help of a very efficient regenerator we may put $t_1 = 200$ deg. Fah. The water evaporated would be nearly 7 lb. per pound of coal, but the work done in overcoming back pressure would be practically the same as in the single-cylinder engine, viz., ·05-horse power. If we put $S_v = 1$, we get $E = ·23$, and the maximum attainable work per pound of coal per hour equal to ·71-horse power, so that the maximum attainable indicated horse-power is ·66-horse power, which corresponds with a consumption of 1·5 lb. of coal per hour per indicated horse-power. In the case of the best quick-speed marine engines, the fuel consumption does not exceed this, and in the case of slow stroke compound beam engines it is much less. We have, therefore, in this case, not only a proof that the specific heat of steam is equal to the specific heat of water, but also that the value of Q J is equal to many times that of $P\,(V - v)$.

November 6th.　　William Donaldson.

---

Sir,—Mr. Henry Cherry writes to you that my statement "that the abstraction, not the supply, of heat is that which is really effective in producing mechanical power," is open to adverse criticism. I did not state this. I stated that "in the case of pieces in tension it is the abstraction, not the supply, of heat that is really effective in producing extra mechanical power." Criticism that proceeds by the method of asserting that one has said something totally different from what one has actually said is not valuable. I myself do not think it worth printing. Those who have studied Clausius, or any other of the great teachers of thermodynamics, both carefully and cautiously, will readily recognise my statement to be true, even although it may possibly be new to them. If Mr. Henry Cherry be unable to recognise that the omission of the reference to "tension," and also of the word "extra," or of either of them, from my statement totally changes its meaning, that would prove him incompetent to discuss this subject.

Perhaps one should feel no surprise at such gross misquotation by one who is careless enough in stating the second thermodynamic law in the form preferred by Clausius, to turn it upside down so as to assert the exact and precise contrary of the truth, as Mr. Cherry does in his letter. But Mr. Cherry imputes to me that I "undervalue Carnot's, work" and that is more serious. On the contrary, I value his work highly, and protest "against the unfairness of fathering those mistaken notions upon Carnot." I also incidentally pointed to his having given a "mathematical demonstration of an all-important law in thermodynamics." If the law is all-important, surely its demonstration gives Carnot a claim to high appreciation; I do not for a moment suggest that this is his only claim.

In reply to the pleasant letter from the gentleman who, in his signature, hiccups over the Greek symbol for temperature, it is perhaps right for me to say that I did write to defend the statements of Mr. Maurice Cross. It seems also necessary to say that I have at no time "found out that Carnot's theorem represented nothing, &c." It represents the "mathematical demonstration of an all-important law in thermodynamics." It is twenty years since I have recurrently taught that his "cycle" is quite different from the indicator diagram of any actual heat engine. Those who have learnt these notions from me do not seem to have been much upset by them. I trust they understand the true teachings of Carnot better in consequence.　　Robert H. Smith.

Mason College, Birmingham, November 3rd.

---

Sir,—Every steamship owner and shipbuilder should read the following figures. When the Great Western crossed the Atlantic in 1838 she worked with 5 lb. on the safety valve, or what is now called 20 lb. steam cut-off at ¾ stroke, and then discharged into a vacuum condenser having a back pressure of 2½ lb. from imperfect vacuum. A cubic foot of water boiled off into 20 lb. steam, and worked through such an engine, would produce "theoretically" 3,976,934 foot-pounds, and the Great Western crossed the Atlantic with that steam at the rate of ten miles an hour.

The Lucania now crosses the Atlantic at twenty-five miles an hour, but she uses 180 lb. steam expanded to 10 lb. before it is let into a vacuum condenser, which, like the other, has a back pressure of 2½ lb. from imperfect vacuum. A cubic foot of water boiled off into 180 lb. steam, and worked through such an engine, would produce "theoretically" 33,382,427 foot-pounds, or 8⅓ times as much power as the Great Western was able to develope from the same quantity of water and of coal. Every engineer knows that the very same coal as boils off a foot of water into 20 lb. steam would boil it off at 180 lb. pressure or at any higher pressure. The Lucania then has gained all that extra power and extra speed by simply using stronger boilers and suitable engines to work the high-pressed steam.

If, now, steamship owners instead of using 180 lb. steam would use still stronger boilers, and boil off their water into 500 steam, and expand it down to 10 lb. as at present—the same quantity of coals will do it—each cubic foot of water would produce "theoretically" 83,643,100 foot-pounds, or two and a-half times as much power as the Lucania at present developes with her 180 lb. steam. It is said the Lucania burns 6000 tons of coal on the double voyage out and home, and if her boilers could bear the pressure of 500 lb. steam—they could not—and her engines could work it, then 2400 tons of coal would do the work of 6000 tons, and she might dispense with three boilers out of each five boilers she uses now. That is to say, she could cross the Atlantic at the very same speed as now, and yet she would only burn two tons of coal for each five tons she burns at present, and she might dismiss three stokers out of each five and three coal trimmers out of each five, and carry 3600 tons more cargo than she has room for at present.

These are startling figures, Sir, but they are true, and they are worth the consideration of Messrs. Cunard and of every other steamship owner, because there is no doubt whatever that 500 lb. steam, raised in boilers properly constructed for it, is quite as safe as the 180 lb. steam which all our fast steamers now use.

Penithon, Radnorshire.　　G. A. Haig.

## LABOUR AND LUXURIES.

Sir,—Your correspondent "Hirn" commits the common controversial error; he attributes words and statements to me which I have neither used nor entertained. I never said, "It was of no consequence to a shop-keeper whether he trades with a murderer or an honest man." I did say that a sovereign had just the same purchasing power, and was just as capable of paying for labour or for luxuries, whether it passed through the hands of a murderer or an honest man. Can "Hirn" prove the contrary? I have not the smallest idea what he means by his reference to Socrates, Milton, and a host of others.

"W. A. S. B." has written a sufficiently interesting letter, which has, however, little or nothing to do with what I have said. Indeed, I do not know that there is much difference of opinion between us on several points. On others, "W. A. S. B." draws deductions from my words that they will not bear, and then blames me. I have contented myself with the assertion that so long as a sovereign changes hands often enough and quickly enough, the reason for the change matters nothing, the result to the community at large is the same. Your correspondent appears to think that a sovereign can be spent to more advantage in one way than in another. Within narrow limits this statement is true, and I have not so far disputed it; but in the long run it makes no difference on what it is spent. I have given examples to prove my proposition, and these he does not attempt to prove unsound. He asserts that "it is by no means a matter of indifference how money is spent." My reply is that if we deal with the immediate it may be of consequence; if we deal with the future it is not, and in no case does it make the smallest difference to the worker. A sovereign is a sovereign to a tailor, just as much as it is to a boot maker, or a fisherman, or a firework manufacturer. Your correspondent is setting a value on money which it does not possess, on the one hand; and on the other, he is confounding the action of men and their works and sentiments with the power of gold. This is very commonly done, but it is none the less wrongly done.

"W. A. S. B." holds that labour may be wasted. In that I fully agree with him. A man may waste all his energies in producing that which is entirely useless, or even deleterious or criminal, and is not paid for. This is an aspect of political economy which I have not attempted to discuss. Gold cannot possibly be wasted in a community; but labour certainly can. "W. A. S. B.," like many others, will say that unless the man got gold for his labour he would have to do something else. That may be true, but it does not affect my proposition. The man's labour cannot be considered to be wasted, so far as he himself and the family whom he supports are concerned, so long as he gets gold for it; and the gold is certainly not wasted so long as it does its duty in supplying a man and his family with food and raiment. But gold buried or lost in a shipwreck would certainly be wasted. I have often heard it asked, "How can the production of more gold encourage trade?" The answer is very instructive, and is worth giving here.

A certain individual—whom I may call A—has lived for years with more or less unsatisfied desires. Above all things, he has wished for a handsome carriage and horses; but he had not the wherewithal to buy them. Already in his country there are more coachbuilders than employment for them; more horses than can find purchasers. But A goes in search of gold, and finds it—say, in a watercourse. Thereupon he orders a carriage and horses. The possession of the gold enables him to give employment to the coachbuilders who are idle; but they in turn purchase boots and coats, and such like things which they needed, and so on. Thus it is clear that although A was the first in one sense to benefit by the gold which he found, the whole community shares the advantage with him. It matters, as I have already said a dozen times, nothing on what he spent the money in the first instance. In the long run every one in the community would be the better of it. If immediately after A had found it, B had murdered him and robbed him, the result would have been the same, the community would have been the better of the gold. If, however, B, having killed A, hid the gold, then the community would be distinctly the worse of the hiding. All this about the part which gold—not necessarily money—plays in political economy ought by this time to be fully understood; almost every primer of political economy contains it.

There can be but one answer to "W. A. S. B.'s" questions about his tool smith, but it is equally certain that "W. A. S. B." does not know and does not care whether the two sovereigns with which he pays him were at one time stolen or not. They answer his purpose and discharge their duties equally well in either case. They may for all he cares have been at one time paid for the perpetration of a diabolical crime. They may be blood-stained in the fullest sense of the word. "W. A. S. B." cares not for such things, and if he did he could not help himself.

Your correspondents, in so far as I understand them, seem to say that if gold is spent on certain works instead of others, the community will in the long run be better off. My reply is, that the improvement will not be due to the gold, but to the labour; and furthermore, it remains to be proved that in any case it is possible to spend gold in such a way that it must do more good than it would if spent in another way. I repeat, that so far as the functions of the gold itself are concerned, that is not true. To simplify matters, however, I will state a case for "W. A. S. B.," and ask him for an answer. If £50,000,000 of gold came into this country to-morrow as a free gift, just as a much larger quantity came by discovery into California, how could it be spent to do more good in any one way than another? Let us suppose that there were two great claimants for it, agriculture on the one hand, manufacturers on the other. Is it to be supposed for a moment that the manufacturers could get this gold without benefiting the farmers, fruit growers, meat and wool growers. Is it, on the other hand, conceivable that the farmers getting hold of the money would not do good to the manufacturers? It is the old story of the belly and the members. No matter what the gold is spent on, all the benefits that the gold can confer will be conferred, and "W. A. S. B." has not even attempted to advance a single argument to the contrary. His error is that he attributes to gold powers that it does not possess. Y. X.

London, November 4th.

SIR,—Owing to absence from home I have been unable to reply earlier to your correspondent "Y. X.," but I notice in the meantime that he has been fairly well handled by "Hirn" and "W. A. S. B." in a manner that effectively disposes of many of his contentions. The most striking feature of "Y. X.'s" letters are the glowing inconsistencies between his theories and the examples he advances to prove them. It is difficult to see what the application of political economy, as a science, would be as "Y. X." presents it, for, on the one hand, he tells us that it takes no cognisance of how or why money is obtained, and on the other, that it is of no consequence how it is spent so long as it is distributed. In other words, it matters nothing to the political economist whether the individual makes any return or not for the commodities with which the community provides him. "In any or either case the result is the same; the money has been distributed, and has, to use words in a well-understood sense, given employment." And, again, "So long as a sovereign is spent it is a matter of no importance on what it is spent;" and "so far as the worker is concerned it matters nothing what he produces." All considerations of this sort are, according to "Y. X.," ethics and morals. Well, if this is the case, I think many will agree with me that political economy is a very negative and useless science, and one which is distinctly in want of some ethics in its composition.

If all that is required of money is that it should be "distributed," and that it is of no consequence on what it is spent, will "Y. X." tell us why it is that a country with the soil, climate, and natural advantages of Italy, is in a state of bankruptcy, and its working classes in one of abject poverty? This is a country in which money is distributed and circulated enough in all conscience. What could be a better and more regular distributing agency for the national money than its vast army and navy, and its still more vast army of police, Custom House officers, and officials generally? The amount of stores, clothing, equipment, food, &c., that these men consume, causes the circulation of vast sums of money, and gives employment to thousands of workpeople in every branch of industry.

Why is it then that with an employment—finding and money-spending apparatus greater in proportion to its size and population than any country in Europe, it is at the same time the most poverty stricken? Would "Y.X." suggest that to double the army, navy, officials, &c., of Italy, and so double the amount of money spent among the population, would tend to improve matters? Hardly, I think, but I should not be surprised if he calls such considerations "sentimentalism," and declines to deal with the question accordingly.

As regards the way in which your correspondent disposes of my case of the "pork" millionaire, I readily admit that I know nothing of the details of a pork corner, but yet I fail to see that this affects the case, or even if it does, that, as "Y. X." says, "he distributes more gold among the farmers—*i.e.*, in buying up the pigs—than they would otherwise have got." For suppose the farmer had the day before sold his pig, not to the millionaire, but direct to the butcher for, say, £8, is he not as well off as if he had sold it to the "corner" man for £8, and is not the butcher better off than if he had to pay the latter £9 for it instead of £8 to the farmer? But in case this is not sufficiently convincing for "Y. X.," may I be allowed to quote an actual case recently stated in the daily papers? It is the announcement of the death of M. Wattine, of Roubaix, "whose colossal syndicate 'rig' will long be remembered on the wool markets of Europe. By simultaneous action all over the world the Wattine ring was enabled to buy up all available wool to the amount of 200,000,000f., on which the eventual profit was about 25,000,000f." Instead of a problematical corner in pork, here we have an actual corner in wool, and I fail to find anything in the arguments of "Y. X." which would serve to convince such as myself that the world was better for having to pay 200,000,000f. for 175,000,000f. worth of wool, simply because the persons composing this ring were afterwards gracious enough to "redistribute" in the shape of "employment" the 25,000,000f. which they had previously netted from the public; though if distribution of money is all that is required no doubt "Y. X." regrets that the sum netted was not 50,000,000f.

It will be noticed that in his letter of September 25th "Y. X." says, "It would, perhaps, not be easy to select a worse example of mis-spent money." But, if money can be "mis-spent," how can it be at the same time a matter of no importance on what it is spent? For, if money can be mis-spent, it can surely also be well-spent, and this is the very point which "Y. X." has all along denied, and on which the whole controversy has hung. How can "Y. X." maintain that it is of no importance how money is spent when he says in his letter of October 22nd that the community would be better off if the widow died than if the gardener died? The simple and evident reason is that the gardener does something in return for his sovereign, and the widow does not. It is the same with the army and navy of Italy. They are all "widows," if you will, and very expensive widows too—it is only a question of degree; and if they were "gardeners," or in other words producers, the community of Italy would be equally as better off as the community in the example cited by "Y. X."

There are many other striking inconsistencies in "Y. X.'s" various letters which are evidently apparent to others besides myself, and I think it still remains for him to show a little more convincingly than he has done so far how it can be a matter of indifference to the community how money is either got or spent.

Macclesfield, November 7th. R. G. B.

## GOVERNING ELECTRIC LIGHT ENGINES.

SIR,—If one may judge from the tone of his letter in your issue of the 26th inst., Mr. Kuhne apparently mistakes hard language for righteous indignation. Nevertheless I give the apology he suggests, so far as the apparatus he illustrates is concerned, as it was not until kindly furnished with details by Messrs. J. Storey and Sons, the makers, that I was aware of the improvement necessary to obviate the defect I mentioned, having already been made; and I would have it understood that my remarks referred wholly to the earlier form of the apparatus. At the same time I have reasons for believing that the number of apparatus of the later form represent only a moderate proportion of the Proell apparatus in use; but whether or not the earlier apparatus are still in use, the manufacture was only discontinued at a comparatively recent date, and from Mr. Kuhne's remarks it is admittedly defective. The extent to which it is defective is apparently the only point of difference left; and as Mr. Kuhne says he is unable to show this graphically, except by some cumbersome method, I suppose that is the reason its manufacture was continued so long without those interested finding it out. This may account for the hard language. At any rate the accompanying Figs. 3 and 4 will show that no great stretch of imagination is required to understand that when the apparatus reaches its mid position the bell-crank $R_2$ will pass into gear with its lifter $h_2$, and if the trip takes place immediately afterwards, will prevent the valve falling on its seat until the bell-crank is moved up to its engaging position, when the valve will close. Why this should be cumbersome to show graphically I cannot make out, but I have invented a system of trip gear diagram that will show it very simply, and if it helps Mr. Kuhne to sooner understand the gears he may represent, I shall be perfectly satisfied; if not, then it may interest others. The case taken is that of my previous letter, viz., C O E = 38 deg. negative advance angle and A O F = 6 deg. lead angle. The apparatus is in its extreme position in one direction at the position O M of the crank, and the descending bell-crank will come in contact with its lifter at the position O E, and as both lifters are closely confined by the bridle on the valve stem, whatever movement one makes the other must make also. Bearing this in mind, it will be understood that at any position of the crank the position of both lifters is at once indicated by a line crossing the centre. At the position O H the apparatus is in its mid position, and at O E is in its other extreme. If the trip does not take place before this position is reached, the valve will remain open until the position O V is reached, and consequently the angle between the mid position O H of the apparatus and the position O V produced, that is O G, is the angle during which there is the possibility of the valve being arrested, and for some part of it, determined by the condition of the trip edges, actually is arrested and prevented from closing until O G is reached. If Mr. Kuhne is able to point out where this differs from my calculations and is misleading I shall be glad to stand corrected. It will be understood that in the statement, "If the trip does not take place before this position O E is reached, the valve will remain open until the position O V is reached," only one side of the apparatus has been taken into account; for if by any means the governor could drop far enough to admit of no trip taking place, the valve, instead of closing at O V, would at the position O H produced be lifted by the other side of the apparatus, and so prevented from closing at all. This, however, does not affect the interval of no "control" when the governor is correct—or not—in its adjustment.

Fig. 1

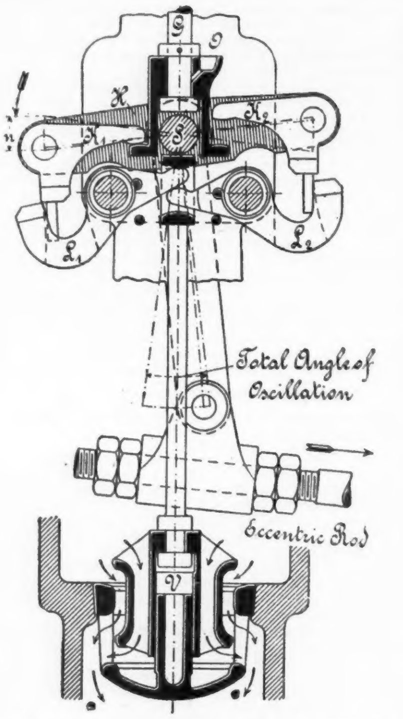

Fig. 2

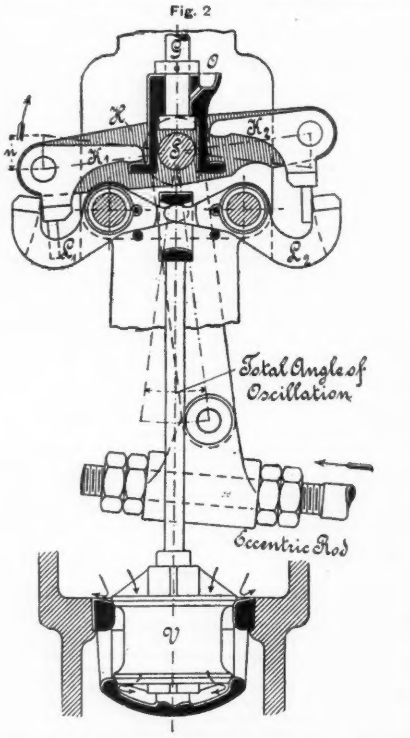

Fig. 3

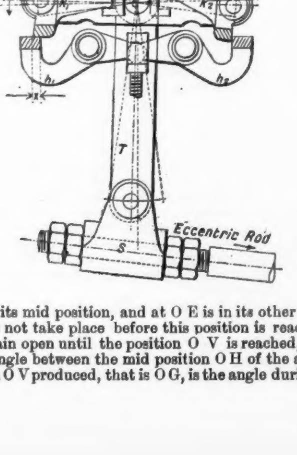

Fig. 4

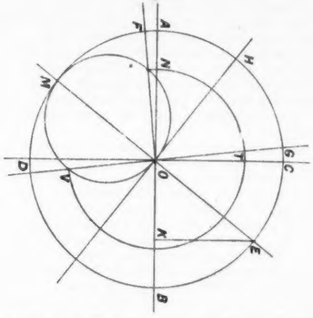
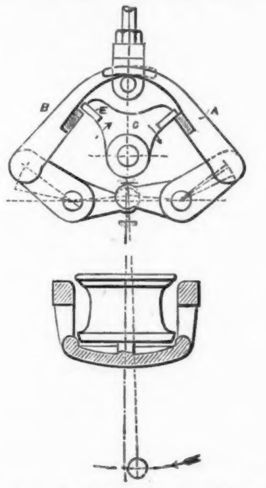


240, Wallgate, Wigan. JAS. DUNLOP.
October 27th.

SIR,—Will you kindly insert the following in reply to the letter of M. Jas. Dunlop contained in your issue of the 19th instant, which I had only brought under my notice this morning. Regarding the peculiar feature in single-valve automatic trip gear referred to, Mr. Dunlop may rest assured that the peculiarity does not exist in my gear, the enclosed sketch of which will doubtless make this clear. The gear is shown lying in a position a little beyond zero cut-off. The active edge is bearing on the right-hand latch A. It will be evident that should the governor cause the latch A to be released at this point, the idle latch B cannot prevent the valve from closing, as the lever on which it is hung is prevented from rising by means of a spring. At any point of the stroke earlier than this the face E on rising simply pushes the latch B aside, so that should release of the active latch occur during this interval, the valve still seats itself automatically.



Maryport, October 29th. W. CAMERON.

## LOCOMOTIVES AND TRAINS.

SIR,—In last week's issue your correspondent Mr. Buchanan appears to recommend increased rubbing surface on locomotives, but does not say from whence he would obtain the necessary increase of pressure on the brake-blocks, without which it would be useless to increase their surface, which would simply mean that the pressure per unit of area would be proportionately less, the total pressure on the brake-blocks remaining the same. For we have by the second law of friction, that the amount of friction between two surfaces is independent of the extent of surfaces in contact. It is the usual practice to take the whole weight of carriages as brake force or pressure, and 50 per cent. of the weight in the case of engines and tender. If we assume that the forces producing a stop, including brake power, friction, gravity, &c., are constant and acting uniformly throughout the stop, then if

$f$ = the brake force or pressure in percentage of the weight of the train.
$d$ = the distance moved by the train after application of brake.
W = the weight of the train.
$v$ = the velocity in miles per hour.
$x$ = the retardation in percentage of the weight of train.

Then $f = \frac{x}{100}$ W

whence

$$\frac{x}{100}\,\mathrm{W}\,d = \frac{\left(\frac{5280}{3600}\,v\right)^2 \mathrm{W}}{2 \times 32{\cdot}19}$$
$$= \frac{2{\cdot}15\,v^2\,\mathrm{W}}{64{\cdot}38}$$
$$\therefore x = \frac{215}{64{\cdot}38} \cdot \frac{v^2}{a}$$
$$= 3\;34\;\frac{v^2}{d}$$

The wheels of a train should never be allowed to skid, that is to say, become locked to the brake-blocks, for in that case the retarding friction is considerably decreased, owing to there being only the sliding friction between the wheels and rails, instead of the sliding friction between the wheels and brake-blocks, and the rolling friction between the wheels and rails when the wheels do not skid. It is very evident that this will limit the amount of brake force which can be applied to a train without skidding the wheels, which is also dependent upon the velocity of the train when the brake is applied. The coefficient of friction at high speeds is less than at low speeds, consequently the brake force or pressure which may be applied without skidding the wheels is greater in the former than in the latter case. Now a brake is most efficient when it is acting at a maximum pressure without skidding the wheels. It should be applied immediately at this maximum pressure corresponding with the speed of the train at the instant of application, and should graduate down in accordance with the consequent reduction in speed, otherwise the brake pressure which would not be sufficient to skid the wheels at the higher speed would easily do so at the lower speeds. Any deviation one way or the other from this maximum efficient pressure will detract from the efficiency of a brake, in the one case owing to insufficient pressure, and in the other through skidding the wheels as pointed out above. When the train is moving at its highest speed attention to this may be sufficient to avert a collision.

The lesser the difference between the retarding force of the carriages and that of the engine and tender, the less will be the stress on the connecting draw bar. It has, however, been found to be advantageous to give less retarding force to the engine and tender in proportion to its weight, than in the case of the carriages, inasmuch as the consequent drag by the engine and tender on the following vehicles decreases the unpleasant jar which would otherwise occur on the application of the brake.

If we take the weight of the train as given by Mr. F. Bowles in his letter of the 19th ultimo, viz :—

Weight of the two engines and tenders = 162 tons.
Thirteen 6-wheelers 169 tons, and one Pullman 25 tons ... ... ... ... } = 194 tons.
Total ... ... ... ... = 356 tons.

Taking the brake force on the above assumption we have

$$\left(\frac{162}{2} + 194\right) = (81 + 194) = 275 \text{ tons.}$$

The percentage of retarding pressure will be

$$\frac{275}{356}\,100 = 77{\cdot}24 \text{ per cent.}$$

Assuming the average coefficient of friction to be about 0·15, and the speed sixty miles per hour, and applying the preceding formula, we have

$$77{\cdot}24 \times 0{\cdot}15 = 11{\cdot}586 \text{ tons, or say, } 11\ 6 \text{ tons, and}$$

$$11{\cdot}6 = 3{\cdot}34\,\frac{(60)^2}{d}$$

$$\text{whence } d = \frac{3600 \times 3{\cdot}34}{11\ 6} = 1036{\cdot}55\text{ft., or say, } 1037\text{ft.}$$

Now if we take the engines and tenders as fully braked in the same manner as the carriages, we get 100 × 0·15 = 15 tons.

$$\therefore\ 15 = 3{\cdot}34\,\frac{(60)^2}{d}$$

$$\therefore\ d = \frac{3{\cdot}34 \times 3600}{15} = 801{\cdot}6\text{ft., or say, } 802\text{ft.}$$

This gives a saving in stopping distance = (1037 − 802) = 235ft., that is to say, the train would be stopped in a distance of 235ft. less in the latter than in the former case, but the disadvantages might be greater than the advantage gained.

EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
November 5th.

Sir,—I did not in my former letter—which you printed on the 26th—touch upon the question of using two engines for one train, because I do not agreee with Mr. Thompson and Mr. Bowles on this point, and think your article is quite correct. Mr. Thompson's statement that a re-built 6ft. coupled L. N. W. R. engine could—punctually—take a corridor train over Shap with fourteen on is going too far; and when he speaks of an old N. E. R. engine and the work it could do now, he forgets the great increase in the weight of the coaches and the greater booked speed.

I think you will find that locomotive superintendents, drivers, &c., on lines where both six-wheeled and bogie stock is used—like the Caledonian, L. N. W., Midland, G. S. and W. R., &c.—are quite convinced that weight for weight when you have a shorter wheel base and less rigidity the trains are easier to haul, and also cause less wear to the wheels and rails; and that it is chiefly for this reason that the West Coast, G. W. R, G. S. and W. R., Midland, Highland, Caledonian, &c., stock—for fast trains—is all being built on bogies.

As for Mr. J. Y. Buchanan, who was in the Northallerton smash, and his letter to you in your last issue, his general theory that you cannot brake your train too well is most excellent, and he will be surprised to hear that on the East Coast stock only four wheels out of six can be braked, whereas had they been bogie carriages every wheel would have been braked. Things are not so bad as he would make out, however, on the engines, as the driving wheels of all engines fitted with the Westinghouse brake can be instantly so powerfully braked as to skid the wheels—a point just short of this is best—as I have often seen done. I fear Mr. Buchanan lays too much stress on his "area of rubbing surface," whereas the point is the amount of force employed to press the brake blocks on. He is quite right when he says that all the wheels of the locomotive bogie should be braked also; in short, every wheel in the train should be, as is now being done on all the good lines in America. I give above two points in favour of bogie stock, and a third is, that in a smash it does not so easily telescope or collapse; in short, we should have trains of carriages like the Americans, who are nearly half a century ahead of us in passenger stock.

15, Abercromby-place, NORMAN D. MACDONALD.
Edinburgh, November 5th.

Sir,—Mr. Bowles does not answer my question, which was simply, on what railway Mr. McDonald's locomotive with pick-up which he specified might be found. I judged this a matter of interest to other readers besides myself, and do not think I am entitled to the exclusive information he suggests. Of course if the engine is only theoretical, I cannot expect a plain answer to my query. SCRUTATOR.

London, November 2nd.

### TRACTION ENGINES ON ROADS.

Sir,—I have charge of 1029 miles of main road, and find in many cases traction engines have helped to make the roads as they find the weak places, and these once cut out, the bottom carefully pitched, and the top metal consolidated, they do little harm. Given a good road with a hard subsoil, a traction engine is not an excessive weight for an ordinary road, but with wet soft clay or peat the road lifts or puffs, the metal eats through, and the road is ruined.

In this county, hitherto, a very liberal policy has been adopted; it has been thought the roads should be made to carry the traffic, and engines are allowed to run between sunrise and sunset. Your suggestion that the traction licence should pay for the repairs is impracticable—the sum received is so small. The exemption of engines used for agricultural purposes is a mistake, every engine should be licensed, and the county surveyor should have power to stop their use on roads to be specified on the licence, or for any failure to comply with the statutes—two men, a driver and flag man, and occasionally a brakesman, are all that are required.

The present state of agriculture requires every obstacle to progress and transit in rural districts to be removed, and I look to improved traction engines rather than light railways as the solution of the problem, with horse or steam omnibuses carrying parcels, milk, and passengers on definite lines of road, with proper hours of stopping and starting. The difficulties are old and worn-out engines purchased by impecunious men and placed on the roads. The system of purchase hire adopted by the manufacturers stops all improvement. Excessive competition reduces prices, so that a poor class of workmen are employed. Carrying too heavy loads, causing damage to the roads every time the engines stop and start. The greatest of all, defective driving wheels, the use of spikes, and the badly designed diagonal bars. Frightening horses; horses that pass a steam roller quietly are frightened at a traction engine. The horse is an animal very sensitive to smell. Steam rollers are under competent engineers, are kept clean, and good oil is used. Traction engines belonging to private owners are generally as dirty as an old cow, and the cheap oil can be smelt a long way off. The horse dilates his nostrils, and will not face it. They can be seen to do the same thing over a sewer manhole. They do not like the look of the roof lately added to traction engines, and this has caused one or two accidents in this county. Personally, I would not let them run when fox-hunters are about; they hate traction engines.

The existing statistics and legal decisions would enable any authority to ruin a traction engine owner if they wished, but the remedy is a mechanical one. Improve your engines, and opposition will die a natural death. ROBERT PHILLIPS,
County Surveyor for Gloucestershire.

November 6th.

### THE INVENTOR OF THE BLOCK SYSTEM.

Sir,—In your issue of the 25th ult. you state that the late Mr. Edwin Clark was the inventor of the "block system of railway signalling." Mr. Clark's system is not the system of railway signalling compelled to be adopted throughout the United Kingdom. With Mr. Clark's system employed on the London and North-Western Railway between London and Rugby in 1855, one train was allowed in each section, and where tunnels did not intervene a second, third, and fourth train was allowed to follow on the same length if necessary, with a verbal caution from the signalman, after the driver had sufficiently slackened speed to receive such a caution. This is in accordance with the Government Inspector's report before 1865, the date of my publication, and is also mentioned in the late Sir G. Findlay's work upon "Railway Working," &c. In the present system of railway signalling, known as the "absolute block system," commonly termed the "block system," one section is kept empty behind the trains, and with permissive block working a train is allowed in the empty section with a verbal caution to the driver, "station blocked," "section clear."

CHRISTOPHER J. LITTLE, Mem. Soc. Arts.

17, Groombridge-road, South Hackney, N.E.,
November 7th.

### MORE DOUBTS AND SOME CONJECTURES.

Sir,—If I understand Mr. Roots' aright he has advanced a very startling proposition, namely, that the action of gravitation is not universal. If it be, why do the fixed stars retain their relative distances?

The answer is, first, that they do not retain them, but that their distances are so vast that we are unable to measure the rate of change of place; and, secondly, that all the "fixed" stars are rotating in vast circles, so that centrifugal force supplies stability.

Since reading Mr. Roots' letter I have consulted two or three works on astronomy, but I can get no information concerning the opinions of authorities on this point. In fact, the question is as though it had never before been raised. M. A.

Woodstock, November 5th.

### CORROSION OF PROPELLER SHAFTS.

Sir,—You were good enough to publish a letter of mine on a suggested remedy for the corrosion of propeller shafts, together with a sketch. I am sorry to say that there is an obvious mistake in the illustration as given by you. The bevel of the liner on the after end of the shaft should be the same as shown on the forward end, the full lines running out to where the dimension lines terminate. The liner is shown correctly at the forward or coupling end.

London, Oct. 26th. CONSULTING ENGINEER.

### POUNDS WEIGHT.

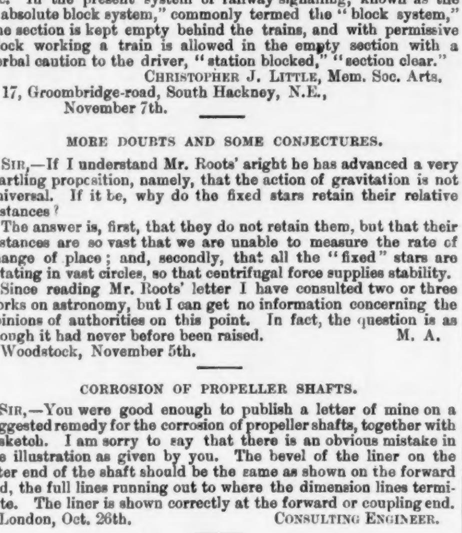
Sir,—In the notice of the new edition of my "Deschanel" in your last issue, the phrase "lbs. weight per square inch" is given, in quotation marks, as one which I carefully insist on. Permit me to say that I have neither insisted upon it nor used it. I employ the ordinary phrase, "lbs. per square inch."

Derryvolgie-avenue, Belfast, J. D. EVERETT.
November 7th.

### A BICYCLE PROBLEM.

Sir,—Will any of your readers be good enough to solve the following problem?

The sketch represents a common form of rear-driving safety bicycle standing on the ground with its cranks vertical. The bottom pedal is pulled by means of a piece of string in the direction indicated by the arrow. In which direction will the bicycle run? J. HARBOTTLE.



18, Crossley-terrace, Newcastle-on-Tyne.

## STEAM ENGINE MAKERS' SOCIETY.

The seventieth anniversary of the above Society, which was established in November, 1824, has during the past week been celebrated in various ways by the different branches throughout the country. The most important of these celebrations was, however, held at Manchester, the headquarters of the Society, on Saturday, when there was a very numerous gathering at the Belle Vue Gardens of members from the surrounding towns, and special interest was given to the occasion by the presence of Sir Wm. H. Bailey, the Mayor of Salford, accompanied by Lady Bailey, and, attended by his Marshal, his worship, wearing his chain of office, receiving quite an ovation, which in large measure was no doubt due to the leading part he has taken in the promotion and successful completion of the Manchester Ship Canal, together with the high reputation he enjoys as an employer of labour in the district. Sir William Bailey, in the course of an interesting address, spoke of his own and Lady Bailey's long connection with the making of steam engines, and pointed to the invention of the printing press and the steam engine as having been foremost in the promotion of peace and prosperity, whilst the marine engine in particular had done much to keep famine away from our shores. Personally he had a great respect for trade combinations. There was just now a great talk of old-age pensions, but so long as they had mutual aid societies similar to their own, the Oddfellows', Foresters', and Druids' societies, he could not see any occasion for the old-age pensions of politicians. The objects of societies like that were to assist their own poor, and so long as they carried out that principle, there was no necessity for the Government to step in, because the moment the Government came on the scene the people were shorn of some of their liberty. As a general rule employers and employed, in their trade at least in Lancashire and Yorkshire, had worked well together in equalising the rate of wages, and the more trades unionists pushed on with their efforts to equalise the rate of wages of their fellow workers in other countries, the better it would be for them in this country. Mr. James Swift, the general secretary, gave some interesting particulars respecting the early history of the Society and its operations since its establishment seventy years ago. He said that as the Combination Laws were repealed in the autumn of 1824, the Steam Engine Makers founded their Society in the November following, and from that time it had retained its position as a bonâ fide trades union. At first it appeared to have been more of a social club, as its rules provided more for entertainment at their meetings than paying its members benefit. This was continued until 1833, when sick and funeral benefit was instituted, and at a later period superannuation and out-of-work benefit. As evidence of what had been done in the past twenty years he gave the following figures, showing the financial operations of the Society. They had paid for unemployed donation and railway fares £74,286; sick benefits, £52,130; funeral benefits, £15,602; superannuation to aged members, £28,130; disabled compensation, £4470; benevolent grants to members, £1558; and contingent benefit, £5100; making a total of £181,384, in addition to which there had been working expenses amounting to £32,254, bringing the full total up to £213,638. The above figures showed that in the twenty years, whilst they had distributed this large sum, only 6 per cent. had gone in strike or lockout pay, and if they deducted the years 1879, 1887, and 1892, this was only 3 per cent. of the total expenditure. Another point was the limited sum spent in management, as in 1893 the working expenses were only equal to 2s. 2d. in the pound. As a Society of seventy years' standing, it might be assumed that they had many old men amongst them, but this was discounted by a table in the annual report, showing that one-half its present membership had been admitted within the last ten years. Another proof was that, whilst they paid superannuation benefit to members, ranging from 6s. to 10s. per week, the average cost in 1893 only averaged 8s. 3d. on the members of the Society. They, however, had seen for some time past that this benefit would be a difficulty in time to come, and six years ago the members decided by vote to create a special fund by voluntary levies, with the result that they had now over £11,000 invested on that account with corporate bodies. As to their general finances, their capital value in June last was over £29,000, with a membership of 6500, and their present value per member was not surpassed by any other trade organisation. Addresses were also delivered by members of the council, branch officers, &c., the intervals being filled up by an excellent vocal programme, which included the "Steam Engine Makers' Trade Song," composed by a member of the Society, and at the close an enthusiastic resolution was passed to Sir Wm. and Lady Bailey for their attendance, and the hope was expressed that they might be long spared to maintain the honour recently conferred upon them.

**Naval Engineer Appointments.**—The following appointments have been made at the Admiralty:—Fleet engineer: J. A. Court, to the Iron Duke. Staff engineer: J. Fielder, to the Minerva. Chief engineers: A. V. Blake, to the Pallas; W. G. Mogg, to the Curlew; and W. T. Wiggins, to the Harrier. Engineers: F. G. George, to the Wizard; G. Pascoe, to the Conflict; W. H. Hardwick, to the Swordfish; G. F. Thompson, to the Mersey; A. Hills, to the Janus; J. T. Willoughby, to the Salmon; and T. W. Christian and W. Edwards, to the Victory. Assistant engineers: G. C. Nicholson, to the Alexandra; and R. W. Martell, to the Conqueror.

**Forthcoming Books.**—Messrs. Whitaker and Co. are about to publish a book on "Steel Works Analysis," by Professor J. O. Arnold. We understand that this work is in many respects a new departure. The book has been written specially as a practical guide to assistants in steel works laboratories and students taking up the analytical chemistry of iron and steel with a view to becoming steel works chemists. A new feature will be found in the fact that in articles separate from the practical instructions, the author has dealt with the theoretical principles involved, and has, as far as possible, formulated every reaction taking place. The same firm are about to publish a book by Mr. J. Alexander upon "Model Engine-making." The work embraces locomotive, marine, and stationary engines, and is accompanied by working drawings to scale and dimensioned. There will be twenty-one of these, each sheet containing a separate form of steam engine.

**Death of Sir D. A. Lange.**—The death is announced of Sir D. A. Lange, of Somers-place, Hyde Park, and Hurstpierpoint. He died suddenly on Friday last, in the shop of a hairdresser in Belgrave-mansions. Sir Daniel Lange was the second son of the late Mr. J. W. Lange, of London, who was descended from an old Amsterdam family. The deceased distinguished himself by his work in connection with the Suez Canal; especially in its earlier days, when he was acting as the agent of the Canal Company in London. He received an appointment in 1858 from Said Pacha, Viceroy of Egypt, in connection with the construction of the canal, and was for some years director in England of some of that work, on the completion of which he received the honour of knighthood from the Queen. He was a fellow of the Royal Geographical Society and of the Society of Antiquaries. He had several foreign orders conferred upon him. He published, among other works, "Reflections on the Desert," "The Suez Canal Viewed in its Political Bearings," and "A Narrative of the Suez Canal Works."

**Society of Arts.**—The arrangements for the 141st session of the Society of Arts are now announced. It commences on the 21st of November with an address from the chairman of the council, Major-General Sir John Donnelly. The first regular paper of the new session will be by Mr. Hiram Maxim on his "Experiments in Aeronautics," and this will be followed the succeeding week by one by Mons. Hermite on "The Electrical Treatment of Sewage." Two other papers—one by Mr. Thomas Ward on "Salt," and one by General Michael on "Forestry"—will be read before Christmas. A number of papers for meetings after Christmas are also announced. Six courses of Cantor Lectures are promised, of which the first is by Professor Vivian Lewes on "Explosives." There will be, as usual, a course of juvenile lectures after Christmas; the lecture this year is by Professor Vernon Boys, the subject being "Waves and Ripples." The meetings of the special sections for the discussion of matters connected with India, foreign countries and the colonies, and applied art, do not commence until after Christmas.

**Utilisation of Electricity in the Construction of Bridges.**—A bridge on the arch principle, with a span of 540ft., is in process of construction over the canal near Kiel, at an elevation of 145ft. above the level of the water, to carry the railway from Eckemforde to that town. Four cranes, two of the locomotive and two of the pivoting type, are employed, instead of the usual hoisting appliances, and are all worked by electricity. According to the *Electrotechnische Leitschrift*, loads of ten tons are raised in twenty minutes, and smaller loads at a much quicker rate. With 850 revolutions per minute, the cranes develope 7-horse power, and the electro-motive force of the current does not exceed 220 volts, with a yield of 84 per cent. Two compound dynamos, disposed in parallel, act as generators, driven by a steam engine of 25-horse power. Both dynamos and electro-motors are of the four-pole type, with two indicator coils of Siemens-Martin steel. As the consumption of the motive-power in the cranes was of a very variable character, variable resistances, composed of spirals of nickeline attached to slabs of slate are interposed, as required, by an automatic appliance. The electric circuit comprises three parallel wires ¼in. in diameter, with a total length in both directions of three-quarters of a mile. In order to work the cranes, which have a dead weight of their own of 33 tons, at a speed of 6in. per second, the electro-motor requires 40 ampères and 210 volts.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

### PISTON-ROD PACKING.

(*To the Editor of The Engineer.*)

Sir,—Will any reader tell me whether the metallic packing now so much in favour has a tendency to corrode the rods as asbestos, indiarubber, hemp, and, indeed, all other packing has in a greater or lesser degree?

Gland.

Limehouse, November 8th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, November 13th, at 8 p.m. Address by Sir Robert Rawlinson, K.C.B., the President, and presentation of medals, premiums, scholarships, and prizes awarded at the close of last session. Friday, November 16th, at 8 p.m. Students' meeting. Paper: "The Economics of Direct Current Central Stations," by Mr. John F. C. Snell, Student Inst. C.E., Dr. Alex. B. W. Kennedy, F.R.S., Member of Council, in the chair.

Institute of Marine Engineers.—Monday, November 12th, at 7.30 p.m. Paper: "Some Considerations on the Causes Affecting the Commercial Speed of Steamships," by Mr. J. D. Young, member.

Cleveland Institution of Engineers.—Monday, November 12th, at 7.30 p.m. Paper: "On Different Types of Basic Open Hearth Steel Furnaces," by Mr. Bernard Dawson, Malvern Link.

Northern Society of Electrical Engineers.—Monday, November 12th, at Palatine Hotel, Hunt's Bank, Manchester. at 8 p.m. Paper: "Lighting Installations," by H. A. Henderson, member.

## DEATHS.

On October 31st, at Innerhadden, Allan Duncan Stewart, M. Inst. C.E., of Bunrannoch and Strathgarry, aged sixty-three.

On the 6th inst. at Borstal House, Norwood-road, Herne Hill, Herbert John Allison, Librarian of her Majesty's Patent-office, aged sixty-five.

# THE ENGINEER.

*NOVEMBER* 9, 1894.

## ENGLISH AND AMERICAN LOCOMOTIVES IN THE ARGENTINE REPUBLIC.

In Argentina are two considerable railways. One is the Buenos Ayres Western, and the other is the Buenos Ayres Great Southern. For our present purpose it is unnecessary to go into any details of the construction of these lines. It suffices to say that they exist, and are important financial undertakings. The half-yearly reports of both lines have recently been made public, and are, perhaps, to be regarded as in the main satisfactory. The interest in the lines for our readers lies in the fact that the locomotives of one line are American, and of the other English. The Great Southern Railway is worked exclusively by engines designed and built in Manchester. The locomotives of the Western line have, we believe, all been constructed by Messrs. Baldwin. For some reason which we are unable to give, it was said that the Great Southern Railway could be worked much better by Baldwin, or, at all events, by American, than by English engines. Just twelve months ago a report on the question thus raised was prepared by Messrs. Elordi and Esteves, two Argentine engineers, and this report has been very extensively circulated. It is altogether damaging to the English engines; altogether in favour of the American locomotive, and in every way curious reading, exemplifying as it does the methods by which engines built in the United States are pushed into favour without any special regard for the facts. It will not be unprofitable to consider the report in a little detail.

Messrs. Elordi and Esteves begin by saying that they have found it necessary to make a comparative study of the rolling stock of the two roads. They admit that as regards quality of material and strength the English engines are all that could be desired, but "the builders did not take into account the character of the road bed and track on which the engines had to run, and therefore made them too heavy and the wheel-base too rigid." This is, of course, the old, old story. The English engine is too good for the roads, or the country, or the climate. If only it was worse it would give more satisfaction. "It may be concluded," say Messrs. Elordi and Esteves, "from all the data furnished in this report that the Southern Railway locomotives are but iron masses, entirely injurious to the roads and interests of the company." Now it forms no part of our purpose to defend English locomotive builders against any and every assault. On the contrary, we have very frequently urged that they ought to take more care than they do to supply engines suitable to the imperfect track of new countries. In Great Britain is the best permanent way in the world, and its excellence has no doubt in a measure disqualified English engineers for the work of constructing colonial locomotives. But it has by no means wholly unfitted them for the task. They have not been slow to acquire information and experience; and if they were given a free hand any one of all the great British locomotive building firms could supply suitable engines for any quality of road. It is matter of common knowledge, however, that locomotives for use abroad are usually designed, as far as regards their principal characteristics, by civil engineers who possess no specialised knowledge of the locomotive. It so happens that information is available outside Mr. Elordi's report which enables us to test its accuracy and form an estimate of its value. At the outset there is of course strong presumptive evidence that the American engine, whatever its defects may be, will be a better vehicle for a bad road than the English engine. In the present case, however, this presumption is not supported by the facts save to a very limited extent. One way in which the suitability or the reverse of locomotives for a given road may be tested is by an examination of the working expenses. It is not of course conclusive, but it is good as far as it goes. Now in 1893 for the first half year the working expenses of the Great Southern road were 40·72 per cent. of the total receipts, while those of the Western road, worked with American engines, were 41·95 per cent. There is no great difference here to the credit of American rolling stock. But in the first half of the present year there is a very great difference to the credit of the English engine. The working expenses of the Southern line dropped to 37·15 per cent. of the gross receipts, while on the Western line they rose to 46·95 per cent. Of course, it is to be understood that many conditions affect the working expenses; but it is fair to conclude that if the English engines are "mere masses of iron," it is unlikely that the working expenses should show so considerable a reduction as that we have just stated.

It would occupy much more space than we can spare to follow Messrs. Elordi and Esteves through their report. We find on almost every page of it statements which show that its authors have not mastered all the facts, or having mastered them, have not made them public. We shall confine ourselves at present to one point—the relative merits of the two classes of engine regarded as vehicles, for that is indeed the principal question. The English engines have all been supplied by Messrs. Beyer and Peacock, of Manchester; the American engines by Messrs. Baldwin. As regards weight only, there is little to choose, many of the American engines being heavier than the English. It is a noteworthy circumstance that the English engines very closely resemble in general outline the American engines. For example, Class 5, on the Southern road, a fast passenger engine, is carried on a four-wheeled bogie, one pair of driving wheels, and a pair of trailing wheels. It has outside 16in. cylinders, 24in. stroke, and 6ft. 6in. single drivers. The Baldwin engine on the Western road, which is nearest in characteristics, has also, *mirabile dictu*, single drivers, 6ft. 6in. in diameter. It has a four-wheeled bogie and a pair of trailing wheels, but the cylinders are 18in. by 24in. The load on the drivers is about 16 tons, unless we are mistaken. In the English engine the load does not much exceed 13 tons. In this case it is easy to see that, so far as mere weight is concerned, the English engine has the advantage. In goods engines, again, an interesting comparison may be drawn between the Southern class 7 and the Western class 15. Both have six-coupled wheels, and a pony or two-wheeled truck in front; both have outside cylinders, 18in. by 24in. in the English, and 18in. by 24in. in the Baldwin engine; the latter has, however, 4ft. 6in. drivers, and the former 5ft. 1½in. drivers, but the English engine carries 150 lb., and the American 135 lb. pressure. In both engines the loads are very evenly distributed. Messrs. Elordi and Esteves particularly insist on the want of flexibility in the English engines because of the absence of balance beams. In the single driver English engine there are no beams, in the American engine there are beams between the 6ft. 6in. drivers and the 3ft. trailers. But the goods engines have both got balancing beams; between the leading and driving wheels in the English engine, and between the driving and trailing wheels in the American engine. The wheel base of the latter is much greater than that of the former engine. We might extend this comparison to other engines if it were necessary. Broadly, the fact is that Messrs. Beyer and Peacock have in these engines modified English practice and given their locomotives flexibility, outside cylinders, &c., until it is very difficult to see in what respect the American engine can be superior to the English, regarded as a vehicle. We turn, however, to Messrs. Elordi and Esteves for information on this point, and we get very little. The distribution of weight given for American engines appears to us in many cases to be of doubtful accuracy. We are not told that Messrs. Elordi and Esteves weighed the American engines; and nothing short of an assurance that they had done this would convince us that the figures given are correct. But above and beyond all this, we may ask ourselves what there is about the American engine to make it more flexible than the English? In the latter we find plate frames, in the American engine bar frames. The plate frame should be at least as flexible transversely as the bar frame. Furthermore, in English practice the boiler is only secured to the frames at the smoke box end. The fire box is carried on two angle iron sliding pieces, so that it can expand or contract as it pleases; and possesses, as every railway man knows, considerable latitude of movement; but the American engineer ties his frames to the boiler, in the middle and at each end. Nothing can be more rigid than this combination; nothing more likely to throw injurious stress on the boiler seams. So far, the English engine is more flexible than the American. Again, as regards power of radiating, there is nothing to choose; each has a bogie. In the extended use of compensating levers or balance beams lies the difference. There is more vertical flexibility in the American than in the English engine; but this is not so much, we think, due to the absence of compensating levers—because they are not absent—as to the comparative stiffness of the English springs. Curiously enough, moreover, Messrs. Elordi and Esteves grumble because in one class of English engine they find a transverse compensating lever from one side of the engine to the other, while they are unstinted in their appreciation of a similar device used in American engines.

To sum up this question, the locomotive as a vehicle—would be to write much that has already appeared in our pages. On bad roads, and for moderate speeds, long, easy springs and compensating levers are necessary. On first-class roads, such as those of England, compensating levers and flexible springs are of very doubtful advantage, and at high speeds are a positive source of danger, especially when a train is travelling fast down hill. Under such circumstances the engine is very likely to begin to roll, and finally, if left to itself, to roll off the road. Long springs without compensating levers are better, and they have been found indispensable in France, where the roads are weak. Generally it may be said that on all foreign roads the springs have nearly double the range found best for this country. We believe that English locomotive builders are prone to make their springs too short and too stiff for colonial work; but this seems to be the head and front of their offending; and so far as we are aware Messrs. Beyer and Peacock appear to have avoided this fault in their Argentine engines. Perhaps the springs are not quite so flexible as they might be; but it does not appear that they in any way justify Mr. Esteve's strictures.

Concerning other portions of Messrs. Elordi and Esteves' report we may have more to write at another time, and we should very much like to know what Mr. Gould, the locomotive superintendent of the Southern road, has to say on the subject. Various statements are open to question. The assertion that the American engines can be kept in perfect repair for an outlay of £50 per annum is too much for any exercise of faith. But what can we say to such a statement as the following: "The high-pressure, 160 lb. per square inch, at which the boiler is worked, becomes necessary to overcome somewhat the lack of adhesion." Surely there is here a most ingenious "derangement of epitaphs." The connection between boiler pressure and adhesion existing in the minds of the men who wrote the passage is, to say the least, mysterious. The figures put down for the consumption of coal by the American engines agree with nothing that we have read of in United States railway practice. For passenger trains of 120 tons we can believe that the consumption was as low as 31 lb. per mile; but when we are told that the goods engines only burn 43 lb., we are driven to conclude that the freight trains cannot be much heavier, and we ask why 19in. cylinders are used. Concerning compound engines, too, Messrs. Elordi and Esteves make certain statements which are well worth examination. The report as a whole bears, however, such inherent evidence of bias and prejudice that it loses much of the scientific value which it ought to possess.

### THE UTILISATION AND PURIFICATION OF SEWAGE.

It is by no means an uncommon error to confound the purification of sewage with the utilisation of it, although in many instances the one process is totally distinct from the other. While it is true that the utilisation of sewage frequently does include the purification of it, in both an incipient, and subsequently more thoroughly effectual stage, the latter operation can be and is carried out in districts and localities where there is not the slightest reference to, or intention of, effecting any utilisation whatever, in the proper signification of the term. The word, in the present article, will be understood to mean such an employment of sewage in the service of agriculture, as will extract and utilise all, or nearly all, of the fertilising properties it contains, and will result in the production and growth of plants and crops of various descriptions. Regarded in this sense it is — without reverting for corroboration to the present seat of Oriental warfare—the oldest method adopted for dealing with a national and social problem, which in point of magnitude, gravity, and urgency, has now assumed proportions which have rarely been equalled and probably never surpassed. Bunzlau, in Prussia, can boast of having utilised sewage for over three hundred years. The far-famed and continually-quoted meadows of Craigentenny, near Edinburgh, can date back to nearly a couple of centuries, and the city of Milan is also well to the front on the score of antiquity. It will not, we think, be denied that without dispraising or underrating the value or efficiency of other methods of dealing with sewage separately or combined, such as sedimentation, precipitation, filtration, or by the use of chemicals, yet the generally received opinion is that under certain conditions the fulfilment of which is not optional but imperative, the most effective means of treating it is by causing it to pass over and through land. Whether the agricultural utilisation of sewage should include a preliminary process of purification or clarification before it is passed on to the land, not necessarily by chemicals, is a subject concerning which engineers and scientists are not altogether agreed. In other words, should sewage in its crude or raw state be applied to land? When so applied does it cause the land to become sewage sick, or so saturated with noxious and septic elements as to become dangerous to the health and lives of the neighbouring population? Something depends upon the nature of the soil constituting the sewage farm, but a great deal more upon the character and quality of the sewage itself, as we shall point out.

It is asserted, very naturally, in support of the direct application of raw sewage to land, that at Edinburgh no ill effects, either with respect to the land or the people, have resulted from the irrigation of it for ages, in the foulest and coarsest form, and applied in the rudest and most primitive manner. It should not, however, be forgotten that this statement should be qualified by another, which is to the effect that the Craigentenny meadows are never allowed to be saturated persistently with sewage. When a sufficient quantity has been run on to them, the surplus is carried away to the sea. At Berlin, which with its acquired land of 19,000 acres for sewage farms, is supposed to set an example to the rest of the world, both the broad irrigation and filtration principles are put into practice. A difference worth notice is made in the treatment of the plots upon which crops are grown and those used for the cultivation of grass. In irrigating the former, the sludge is allowed to pass on to the land with the sewage, and consequently remains there after irrigation, when it is ploughed deeply into the ground. In the case of the sewaging of the grass plots there are catch pits provided which intercept the sludge, as it was found that it clogged the surface and seriously interfered with the growth of the grass. When raw sewage is turned on to land, the latter acts, no doubt, in the first place as a simple mechanical filter, leaving the heavier and coarser particles on the surface. The liquid portion which contains the dissolved ingredients, and the lighter and smaller particles in suspension, penetrates into the soil, and thus accomplishes the double purification already referred to. If it is simply a question of removing the larger particles only, the result can be obtained by upward filtration through successive layers of a coarse medium. It must be kept in view that purification, so as to procure a pure effluent, which generally finds its way into a running stream, is the first point to be aimed at; the question of a remunerative return or revenue from the land, sludge, artificial manure, or other manufactured residue, being altogether a secondary consideration. In truth, there is very little necessity to trouble about these made articles, as they rarely sell for anything, although they have been quoted at the fabulous prices of £3 and £4 per ton. The sewage farms at Gennevilliers, near Paris, have been held up here as a pattern for our imitation, and as a kind of reproach to us for the manner in which we deal with the sewage of our own metropolis. We add a few chemicals to a minimum daily discharge of 150,000,000 gallons, and then pump the whole into a river that any capital in the world might be well proud of, to the contamination and pollution of its foreshore, and to the annoyance and danger of those having the misfortune to reside in the neighbourhood of the outfalls. In France, the utilisation of Parisian sewage at Gennevilliers is not regarded with quite the same admiration which appears to be accorded to it here. Some of the French engineers do not consider it by any means in the light of a scientific, economical, or practical utilisation of the alimentary and fertilising properties of the raw material. No doubt the farmers are strongly in favour of the present system, and unquestionably raise very fine crops, considering that they pay nothing for the sewage, which is over abundant in quantity, and exceedingly rich and productive in quality. The whole process has been described as a reckless agricultural waste.

That the composition of the sewage itself is an important factor in the method to be adopted for its utilisation is rendered indisputably manifest by the experience gained at Wolverhampton. The sewage farm there was purchased some twenty-five years ago, and occupied a site possessing the advantages of receiving nearly all the sewage of the borough by simple gravitation. For some years the local authorities made most laudable attempts to effect agricultural utilisation by means of the broad irrigation principle, and that of intermittent downward filtration. Their efforts were unfortunately all in vain, and they were ultimately driven to the conclusion that precipitation, or a preliminary treatment of the raw material in some form or another, must be undertaken before it could, with any beneficial results, be turned on to the land. The fact was that the sewage was rendered so foul by the quantity of refuse, waste water, and bye-products of the numerous trades and manufactures in the town and district, that it was utterly unfit to be applied directly in its crude state to the soil. It was found that when the sewage of only fifty persons to one acre was the proportion employed, the purification effected was of a most perfunctory character, notwithstanding that the percolation extended to a maximum depth of 6ft. By excluding as much as possible the storm waters from the sewers, by the construction of precipitation works, by the erection of plant for pressing and consolidating the sludge, and by the proper preparation of the quantity of land for the final treatment of the effluent, the Sewerage Committee has successfully overcome the difficulties formerly besetting it. Bad as the raw material was at Wolverhampton, that which the Local Board of Nuneaton had to contend with was many degrees coarser and fouler. It was useless to think of irrigating land with a fluid containing ingredients absolutely destructive to all plants, crops, and indeed to all vegetable life. For many years the lime process was employed, then the lime and alumina process, and at present chemical precipitation has been supplemented by filtration through sand and polarite. This treatment is an example of purification only, since the effluent water, after passing from the settling tanks to the artificial filters, is discharged into the nearest stream. It sometimes occurs, in spite of all care and attention in mixing the chemicals, that the clarification is of so imperfect and unsatisfactory a character, that it becomes necessary to pump it up again for fresh treatment, before allowing it to pass into the filters, which are not intended for the filtration of the grosser particles of matter held in suspension.

The purification of sewage simple and pure differs from the utilisation of it, inasmuch as its object is to produce an effluent of a certain standard quality, without much concerning itself about the fertilising qualities possessed by the raw material, although it cannot at the same time afford wholly to neglect them. A simple and very natural process of purification is effected in principle on a certain scale by the agency of rivers. They appear to accomplish this result partly by chemical, partly by mechanical, and partly by biological action. Experiments were recently made in the river Spree, with the object of more fully investigating this question, but, from the unfavourable nature of the stream and other physical features, it was impossible to arrive at any satisfactory conclusion. Although the principle of chemical precipitation is the same for all the different mixtures, the variety in them is almost infinite, and the result in all cases "sludge," which is usually given away to any one who will take it off the premises.

It is alleged that chemical precipitation does not purify but only clarifies raw sewage; and in a very great number of instances the statement is perfectly accurate. It is also asserted, while granting that the purification is effected, that it is only of a temporary character, and that if the effluent be discharged into a river, it will, after a brief period, revert to the same condition of impurity and pollution which it possessed previously to precipitation. It must, however, in fairness be admitted on the other side that experiments conducted at Salford with polarite, and also with an electrolytic process, tend to rebut the temporary theory. The last-named and most recent method of treating sewage seems to promise well, but it has not yet reached a sufficiently advanced stage to enable its merits to be definitely pronounced upon, and its cost is said to be rather high.

Owing to the ever-recurring difficulty of obtaining land for sewage farms, partly due to its high price and partly to the actual scarcity of suitable sites, the cultivation of them has never really had fair play, at any rate in England. It is scarcely possible to avoid at certain times drenching the land with an over dose, and in this respect the farms here are more heavily drawn upon than in Germany. In 1875 a Commission was appointed to investigate and report upon the whole question of the purification of the Seine, with the object of acquiring a part of the forest of St. Germain for purposes of utilisation. The Commission arrived at the conclusion that while the land required was capable of purifying 710,000 cubic feet per acre per year, it would utilise agriculturally only one-fifth of this quantity. Upon this basis it was estimated that 150,000 acres would be needed to accomplish the utilisation of the total sewage of Paris, while 10,000 would suffice for the simple purification of it, provided a suitable outlet was secured for the percolating fluid. Since the population of London may be taken at twice that of the capital of France, the corresponding figures for our metropolis would be 300,000 and 20,000 acres respectively. Calculating from the results obtained at Berlin, 60,000 acres would be sufficient to utilise the sewage of London, an area which accords far better with the usual proportion between population and acreage than the extravagant estimate proposed for the city of Paris.

### COAL CARRIAGE BY LAND AND SEA.

It is now definitely stated that the question as to the "increase" of rates for the carriage of coal by railways will be brought before some of the authorities for decision. It may be remembered that at the beginning of last year there was a change in the method of charging for carriage of coal—that is to say, that the "ton" was brought down from 21 cwt. to 20 cwt., and the contention of the coal merchants is that there should be a corresponding reduction in the cost of conveyance. For months the question has been agitated; and last month a deputation from the Society of Coal Merchants waited on the managers of the railways and explained their views. The coal merchants agree that there is no likelihood of going back to the carriage of 21 cwt. to the "ton," but that the change for carriage for the ton should be lowered in proportion. On the average it is claimed that the alteration in the method of assessing the charge means an alteration of about 2¾d. per ton, and with such a reduction the coal merchants would be content. But whilst the sum is small in the actual variation for the ton, it is very large in the aggregate, whether regarded by the coalowners or the railways; and it is not likely that it will be readily disposed of. There are, however, other questions that interfere with the ultimate decision—the relation of the railway rates to the freight on coal carried by sea. It is sometimes pointed out that the sea freight on coal is "only 3s. 4½d. per ton," but this is an inadequate statement. It is that rate on the summer average; but in winter the rate rises to 4s., and even higher; and it must not be forgotten that there is to be added to that the cost of the railway carriage from the colliery to the coal-port, which may vary from 1s. 6d. to 2s. 10d. per ton, so that the cost in the Thames is very different for carriage from the 3s. 4½d. that is put forward. The percentage of small produced is very much larger in sea borne than in land borne coal. On the other hand, the railway charge is that from colliery to depôt, so that the charge is known, but that of the sea-borne coal is from port to port only. It would be well if the question could be so treated that the public could grasp the relative cost of the coal, of its carriage by the two methods, and of the way in which the total tion is adopted now "employ about 90 per cent. of the charge for coal in the metropolis is arrived at, for on all these subjects there is only a very limited knowledge amongst the general public. The legal investigation of the question that seems likely now to ensue in consequence of the change in the nature of the "ton" will probably do much to enlighten the consumers as to the actual sums paid for coal, for carriage, and for cartage; and it will also throw light on the relative cheapness of the two methods of carriage by which the supply of the metropolis and other centres of consumption is effected.

### MINERS' WIVES AND MINERS' WAGES.

At Parkgate, near Rotherham, on Monday night, Mr. Benjamin Pickard, M.P., was presented with a handsome marble clock, on solid bronze pillars, this being a gift subscribed for by the miners' wives of Rawmarsh and Parkgate, as "a tribute of esteem for the services rendered to the miners during the late coal war." The occasion was chiefly interesting through some remarks made by Mr. Pickard on the coal trade, with special reference to the work which had been done by the miners' wives. He mentioned that in 1880 there were only about 6000 members on the roll of the Yorkshire Miners' Association. The figures, we believe, are now at least ten times that amount. The men were directly appealed to, but the chief influence, it appears, in increasing the numbers and extending the influence of that admittedly powerful Union, was, as Mr. Pickard puts it, "tea parties all over the county to get the sympathy and assistance of the miners' wives." "When the stoppage of last year took place," he added, "no woman who compelled her husband to pay the contribution of sixpence per week regretted the action she had taken. All the money saved, and a great deal more, was returned to the branches, so that the women and children had a fair share so long as there was anything left." It is certainly the case that during the late stoppage the miners' wives of England differed very much from those in Scotland. The Scotch wives, in many cases, were against their husbands remaining idle, while in England the women were amongst the most active supporters of the strike, and have always been the first to make unpopular any collier who was disposed to resume work without obtaining the consent of his Union. Mr. Pickard holds still that the coalowners had no right to require a reduction. "The owners," he says, "knew they were making vast profits, and he is convinced that the money made in collieries was lost through being invested in other works and in large establishments." Mr. Pickard said that they had paid £30,000 to Scotland to help the miners there, and the total amount sent by the Miners' Federation was £74,000 to £75,000. Of the £30,000 sent from Yorkshire, the Yorkshire miners had contributed £24,000 directly out of their own pockets. Mr. Pickard gave it as his opinion that the drift of colliery extension clearly showed that in fifty or a hundred years Doncaster would be the centre of mining, just as Barnsley was the present headquarters. He was sarcastic enough in pointing out that some colliery owners, who had been complaining that they were not making money, had invested £300,000 and sometimes £400,000 in a new colliery, "the money having been previously made out of the old-going concern."

### MINE VENTILATION IN AMERICA.

In no recent official statement is the determination of the methods of colliery ventilation more clearly shown than in the coal reports for the State of Illinois, to which we have already made some reference in The Engineer. A series of reports as to the methods of ventilation are given, and a comparison is drawn between the methods in use in the years 1887 and 1893, which we may summarise as under:—1887, fans, 176; furnace, 286; steam, 27; natural, 304; 1893, fans, 286; furnace, 189; steam, 20; natural, 251. There were slightly fewer mines at work in the latter than in the earlier year, the tendency being in the American coalfield, as in many others, towards a production from fewer and larger mines. It will be seen from the above abstract that the use of the fan is growing with some rapidity, and at the cost of the furnace and other methods of ventilation, and this is even more apparent when the class of mine is remembered. In the official volume to which we have referred it is distinctly stated that the mines in which the fan method of ventilation is adopted now "employ about 90 per cent. of the miners in that State." Seven years ago each of these collieries had, on the average, only 81 mines employed, but now they have about 106, which is a higher average than that of those mines ventilating by other methods; and there is a further fact that is of value in this connection—the mines that are ventilated by fan are the deepest of those that are working, so that measured by numbers or by extent of work, the fan is now doing much the most of the work in the mines of Illinois. These ventilating fans are not large in comparison with those in some of our own mining districts. Two of those added in the past year are "Murphy fans, 6ft. in diameter;" another of the new fans is 10ft. in diameter, and a third 15ft., whilst a Guibal fan 18ft., and another of 20ft. are amongst the largest that are named in the reports for the past year, though there are evidently some others previously in use of a larger size. The facts we have named, however, are conclusive as to the increased dependence that is being placed in the coalfield we have named on the ventilating fan, and it is probable that its efficiency and its economy will, with the growth of the mining industry, cause it to be more and more preferred in the future.

## LITERATURE.

*Electric Light Installations.* By Sir David Salomons. 3 vols. Seventh edition. London: Whittaker and Co. 1894.

*Portative Electricity.* By J. L. Niblett. London: Biggs and Co. 1894.

Sir David Salomons is so well known as the author of a very useful book upon the management of electric light installations, that a revised work from his pen needs little notice on our part to make it widely known. The seventh edition, which is in three volumes instead of one, is stated to be mostly re-written. Vol. I. deals with the management of accumulators, and a comparison of it with the portion of the sixth edition, which dealt with the same subject, shows how much additional matter has been added. The introduction remains as before, but the author now takes a wider view of his subject, and describes types of cells which are used in other parts of the world besides England; and whereas in the earlier editions the descriptive matter related almost solely to the electrical power storage cells, we now have references to such cells as the Tudor, Epstein, Lithanode, and Crompton-Howell. The author describes in his usual lucid manner the method of setting up the cells, and gives very practical hints for the avoidance of difficulties. He draws particular attention to the changes in appearance of the surface of the plates during the processes of charging and discharging. The chapter on "Failures and their Causes and Remedies" is perhaps the most valuable to owners of installations who are not electricians.

Vol. II. deals with apparatus, and an explanatory note is prefixed informing the reader that in this volume a certain amount of information is given regarding the mode of use of the apparatus, but as a rule the general description of the apparatus is given in the second volume, while any special application of it is reserved for Vol. III. The author points out that it may appear at first sight as though the author were prejudiced in favour of certain manufacturers, but he has simply selected the foremost types, which admits of the fact that other makers construct similar apparatus probably as good as the instruments illustrated in this work. Had the products of all known manufacturers been described, a mere illustrated catalogue would have been obtained. In his chapter upon dynamos and motors the author alludes to the number of persons now experimenting with alternating currents having very high frequency and high electromotive force, and describes an alternator built to the designs of himself and Mr. Pyke for experiments in this line. The experiments alluded to are in the same direction as those of Mr. Tesla. A considerable amount of space is given to the description of various types of governors, and several patterns made by the author are illustrated. At the end of the volume are a number of illustrations intended to show some of the many practical uses to which electricity has been put. The book in its present form is more useful than any of the earlier editions, and contains much more information.

Mr. Niblett has had very great practical experience in the subject upon which he writes, so that his work should be of value. He believes that no book has hitherto been written which affords concrete information with reference to the uses and management of portable apparatus for storing electrical energy. The treatise is not intended so much for the use of electrical engineers as for the guidance of those in possession of small secondary batteries; the author has therefore endeavoured to avoid technicalities as far as possible. Comparative tests of the Lithanode and other miners' lamps were made at the Rochebelle mines in Belgium, and the Lithanode lamp was found to be very satisfactory. A translation is given of the report of the mining engineers, from which it appears that these lamps were tested for considerable periods, and found to be superior to the oil lamps in ordinary use. It is somewhat astonishing that so little progress has been made in the practical application of these lamps. Some little time ago many of the London omnibuses were fitted with batteries of this type, and the inspectors were provided with small neat lamps, which appeared to be very convenient; but we have heard nothing of the work lately. Whether the fact that one company was fined for allowing travelling without lights—after the charge in the batteries was expended—led to disuse of the system we cannot say, but the fact remains that it does not appear to make much progress.

It is stated that Custom-House officers are in future to be supplied with the portable electric lamps when looking for contraband goods on board petroleum boats. The application of electric lamps to surgical purposes is described, and also for the exploration of earth borings upon the plan invented by M. Trouvé, who uses an instrument called the erygmatoscope. Details are given of the application of the light to gun sights, and to electric launches, divers' helmets, cycles, and sundry other uses. The author then passes on to a description of the application of the light to decorative purposes, and gives an interesting account of the methods of applying batteries and lamps for use on the stage. The author deals with detectors for explosive gases, and describes his own apparatus, the action of which depends upon the effect of the explosive gas upon oxygen occluded by platinum black surrounding the bulb of a mercurial thermometer.

We believe an extension of the use of small secondary batteries will gradually take place as the use of electricity in private houses becomes more common. When persons can charge their own batteries off the public supply circuits with ease, a greater demand for carriage and other lamps must take place. The book is a useful little work, and gives in convenient form data which previously were scattered in various technical journals.

*Newfoundland as it is in* 1894. *A Handbook and Tourist's Guide to Newfoundland.* By the Rev. M. Harvey, LL.D., F.R.S.C. Published by Kegan, Paul, Trench, Trübner and Co. 1894.

This is a valuable addition to the already long list of handbooks. The question of fishing rights has been so long and so frequently before the public, that the full information here given of this important fishery, and the oldest of our Colonies, will be of peculiar interest. The advantages of the island, however, from an agricultural point of view, the richness of its forests and its mineral wealth, were entirely concealed until some seventy years ago. It has an almost equal length and breadth of 316 miles; its area is 42,000 square miles. Its climate is more temperate than that of North America, though colder than lands of the same latitude in the Old World. Its fishery trade was for generations monopolised by merchant adventurers from the West of England, whose interest it was to retain for their own use all the coves and harbours, and who in order to discourage all immigration, represented the country as a barren wilderness unfit for habitation. The Government, misled by these misrepresentations, enacted repressive laws, forbidding, under heavy penalties, the cultivation of the soil or the building of houses, restrictions which were not finally removed until 1820. From that time substantial progress began to be made, and in 1825 the first road was made; there are now about 1000 miles of postal roads and 2000 miles of district roads. Steam communication was etablished in 1873, and in 1880 the first steps towards the construction of a railway were taken.

In 1864 a geological survey of the island was made, which completely revealed the resources of the country. Large deposits of copper ore were discovered, iron, lead, asbestos, and considerable quantities of coal found, also gypsum, stone and marbles of all colours. To attract settlers to this fertile land it remains only further to develope the railway system, which has been vigorously entered upon. In 1881 a line was commenced from St. John's to Hall's Bay, with branches to Brigus and Harbour Grace, a distance of 340 miles, but owing to financial difficulties, only 33 miles of this were in working order in 1886, when the Placentia line was undertaken from Whitbourne Junction to Placentia. In 1889 a railway was commenced towards Hall's Bay to Brigus, or Clarke's Beach, to be completed in five years, and in 1893 a line was undertaken from Placentia Junction to Port-aux-Basques, about 500 miles in length, running through the richest and most fertile part of the island. The tables of produce, exports, and population, given by Mr. Harvey, are carefully drawn up, and the details of everything relative to Newfoundland are so complete that the reader of his little book could not fail to find himself well informed on the subject.

*Theorie du Navire.* Tome IV. Par J. Pollard et A. Dudebont. Paris: Gauthier Villars. 1894.

This is the concluding volume of the treatise which has already been noticed in these columns. The subjects treated are Dynamics of the Ship; its Movement; Horizontal, Oblique, and Curvilinear Propulsion; Vibration of the Hull of Screw Steamers. The authors are professors in the Ecole d'Application du Génie Maritime, the equivalent of our old School of Naval Architecture, now carried on at Greenwich; and the book is thus presumably the text-book of their students. No analytical difficulties are avoided; and we think that a little more geometrical treatment would have reduced the length of the treatment. The subject of the Rolling of Ships and of the Vibration of the Hull are of pressing importance at the present day; a study of this volume will serve to show how to encounter these difficulties.

## *BOOKS RECEIVED.*

*Mason College, Birmingham, with Queen's Faculty of Medicine. Calendar for the Session* 1894-5. Birmingham: Cornish Bros. 1894.

*Papers and Addresses.* By Lord Brassey, K.C.B, D.C.L. *Work and Wages.* Edited by J. Potter, with an introduction by George Howell, M.P. London: Longmans, Green, and Company. 1894.

*A Text-book of Mechanical Engineering.* By Wilfrid J. Lineham. Part 1—*Workshop Practice.* Part 2—*Theory and Examples.* London: Chapman and Hall. 1894.

*Papers and Addresses.* By Lord Brassey, K.C.B., D.C.L. *Naval and Maritime from* 1872 *to* 1893. Arranged and edited by Captain S. Eardley-Wilmot, R.N. Vol. 1. London: Longmans, Green, and Company. 1894.

*Papers and Addresses.* By Lord Brassey, K C.B., D.C.L. *Naval and Maritime from* 1872 *to* 1893. Arranged and edited by Captain S. Eardley-Wilmot, R.N. Vol. 2. London: Longmans, Green, and Company. 1894.

*Thermo-dynamics Treated with Elementary Mathematics, also containing Applications to Animal and Vegetable Life, Tidal Friction, and Electricity.* By J. Parker, M.A. London: Sampson, Low, Marston, and Company. 1894.

*The Repair and Maintenance of Machinery.* A handbook of practical notes and memoranda for engineers and machinery users. By Thomas Walter Barber, C.E, M.E. With about 400 illustrations. London: E. and F. N. Spon. 1895.

*Ways and Works in India.* Being an account of the public works in that country from the earliest times up to the present day. By G. W. MacGeorge, M.I.C.E. With numerous illustrations and maps. London: Archibald Constable and Company. 1894.

*The "Mechanical World" Pocket Diary and Yearbook for* 1895. Containing a collection of useful notes and formulæ arranged for the use of engineers, draughtsmen, mechanics, manufacturers, and others. Manchester: Emmott and Company. London: 56 and 57, Fleet-street, E.C. 1895.

## HERBERT JOHN ALLISON.

A host of visitors to the library of the Patent-office, Southampton-buildings, will hear with sincere regret of the death, on Tuesday, of Mr. Herbert John Allison, the principal librarian. Who, indeed, of all those who have used the library will fail to remember the courtesy with which he supplied information, or aided them in the search for facts? In no sense or way was Mr. Allison a typical "official." He was a kindly and courteous gentleman who never spared himself in the service of others. He entered her Majesty's Patent-office about forty-two years ago, just about the time when the old Patent Law of 1852 came into force. He was then employed in assisting in classifying and arranging the patents for inventions which had been granted prior to the passing of that Act, and also in the examination of documents filed on applications for patents made under such Act.

About thirty years ago he entered the Scientific Library of the Patent-office as assistant librarian. On the decease of the head librarian—Mr. Atkinson—about twelve years ago, he was appointed to succeed him, and this post he occupied up to the time of his death. To his duties as librarian were —until a few years since—added those of editor of the *Patent Office Journal.* The numerous readers who frequented the Patent-office library, amounting as they do at the present time in the aggregate to 1,403,869, and now numbering over 2000 per week, and including as they did most of the principal inventors, patent agents, and patent experts, as well as the whole of the Patent Counsel of the past and present generation, and also a large number of the general scientific public, will have all had occasion to profit by the knowledge acquired by him during his lengthened service, both in regard to the general organisation of the Patent-office in matters relating to patents, as well as to the splendid collection of scientific works comprised in the library. Mr. Allison early foresaw the increase that the new Act of 1883 would bring in the number of patentees, and strenuously urged the provision of increased facilities for the assistance of inventors. The Scientific and Patent Library with this view rapidly developed under his care, and his one desire was to live to see the complete realisation of his idea, and all the books transferred to and properly arranged in the new library to form part of the building now in course of construction.

For over twenty years he had fulfilled his duties in spite of much personal suffering, due to rheumatic gout, such as would have compelled most people to have sought repose and a pension, and there can be no doubt that his continued efforts in the public service have much to do with his decease at the comparatively early age of sixty-five.

## ALLAN DUNCAN STEWART.

The death is announced of Mr. Allan Duncan Stewart, an engineer of mathematical attainments, well known in Westminster. He was in his 63rd year. He was born in March, 1831, and, after taking mathematical honours at Cambridge, he was 9th wrangler of his year, 1853. He was articled to Mr. Benjamin Hall Blyth, M. Inst. C.E., with whom he was from 1855 to 1858 as pupil, and as resident engineer under him on the Banff and the Portpatrick Railway. Subsequently he practised as a consulting engineer during twenty years, during which time he planned out the Windsor, Ascot, and Aldershot Railway, the Sheffield, Buxton, and Chapel-le-Frith line, the Esk Sewerage, and other works. During this time he assisted numerous engineers in the mathematical work connected with bridges and other structures, including the Redheugh Bridge, the proposed bridge across the Forth, the roofs of Waverley and Dundee Stations, and afterwards, under Sir John Fowler and Sir Benjamin Baker, on the mathematical work of the construction of the accomplished Forth Bridge. He subsequently made the accepted competitive design for Wembley Tower, which, with various modifications, is now in course of construction. Mr. Stewart was elected a Member of the Institution of Civil Engineers in 1883.

## EXPRESS PASSENGER ENGINE, DUTCH RAILWAYS.

The Dutch railways are worked for the most part by locomotives built in England, Messrs. Beyer, Peacock, and Co. having supplied many, and Messrs. Sharp, Stewart, and Co. others.

We illustrate this week one of several fine engines employed in working the heavy express passenger traffic between Cologne and Amsterdam. These engines handle trains of twenty seventeen-ton coaches very comfortably at a high speed. The grate area enables a somewhat inferior coal to be burned satisfactorily. The engines have been built by Messrs. Sharp, Stewart and Co. to comply with the specification of Mr. J. A. Roesingh Van Iterson, the locomotive superintendent of the line.

These engines are used for the through express continental traffic on the Dutch Railway in connection with the Great Eastern Railway Company's route *viâ* Harwich.

*Leading dimensions:—*

| | |
|---|---|
| Cylinders (inside) diameter | 18in. |
| „ stroke | 26in. |
| Wheels, four-coupled, diam. on tread | 6ft. 7⅝in. |
| Centres of coupled axles | 9ft. |
| Bogie wheels, diameter | 3ft. 3in. |
| Centres of bogie axles | 6ft 5in. |
| Total wheel base | 22ft. 9¼in. |
| Boiler (best Yorkshire iron)— | |
| Length of barrel (telescopic) | 11ft. |
| Diameter inside of smallest ring | 4ft. 2⅜in. |
| Length of fire-box, outside | 7ft 8in. |
| Tubes (iron) number | 217 |
| „ external diameter | 1¾in. |
| Inside fire-box (copper) length | 6ft. 11⅝in. |
| „ „ width at bottom | 3ft. 1¼in. |
| Heating surface of fire box | 106 sq ft. |
| „ „ tubes | 1129 sq. ft. |
| „ „ total | 1235 sq ft. |
| Grate area | 22 sq. ft. |
| Height of centre of boiler above rails | 7ft. 6in. |
| Height to top of chimney | 14ft. |
| Weight of engine in working order | 45¾ tons |
| Tender— | |
| Capacity of tank | 2800 galls. |
| Six wheels, diameter | 3ft. 7½in. |
| Weight in working order | 29½ tons. |

The engine is fitted with the Westinghouse brake and Holt and Gresham's steam sand gear. It has an extended smokebox, and is in addition provided with Mr. Adams' patent vortex blast pipe. The engine has the ordinary Stephenson link motion and screw reversing gear.

### TEDDINGTON SEWAGE WORKS.

In our number of 2nd inst. we gave a general plan of these works, in connection with a paper read by Mr. Henry York, F.S.I., surveyor to the Local Board, before the Incorporated Association of Municipal and County Engineers, held at these works on June 23rd, 1894. The present scheme was originated in 1887, and has been carried out entirely under the superintendence of Mr. H. York, Mr. J. C. Mellias acting as consulting engineer. We now have pleasure in illustrating the works more fully by drawings, which will, with a few remarks, explain themselves.

On page 411 is a front elevation and various sections of the sewage pumping and disposal works. The buildings are faced externally with stock brickwork, with dressings of red bricks and red Corsehill stone. The roofs are covered with Westmoreland green slates. The engine-room is faced internally with pressed gault bricks, relieved with red, and has a dado all round of chocolate-coloured glazed bricks, the floor being tiled. The press house is faced internally with red-faced bricks, relieved with buff, and, the bricks being of an impervious nature, all soiling of the walls from the operation of pressing is easily removed. The precipitation tanks are constructed of concrete, faced and coped with blue bricks.

On this page are various details of the sewers and manholes. The sewers are all constructed of glazed stoneware pipes, a large proportion having Hassall's patent joints. The manholes are of pink wire-cut gault bricks, and the tops are circular, of cast iron with wood blocks, and act as ventilators; but this system of ventilation is now being abandoned in favour of shafts. Where a high-level sewer discharges into a low-level sewer a dip or syphon arrangement is provided, which effectually checks all undue splashing of the manhole from the sewage. In manholes provided with disc flushing valves, overflows have been constructed to be of service in preventing the undue rising of the sewage in the event of the valve becoming jammed when closed. The manholes have been constructed with square bricks, laid all headers, thus avoiding the use of purpose-made bricks. We give an elevation and plan of the pumping machinery, consisting of three pairs of hollow plunger pumps fitted with Okes' patent removable valves and seats. The pumps are in pairs, and are placed vertically—the two plungers balancing each other—the cranks being placed in opposite directions. The general arrangement is so designed that any pair of pumps can be driven by either engine; thus one, two, or three pairs can be used at a time to suit the varying requirements of the station. This is effected by the engines driving a lay shaft, common to all the pumps, and as

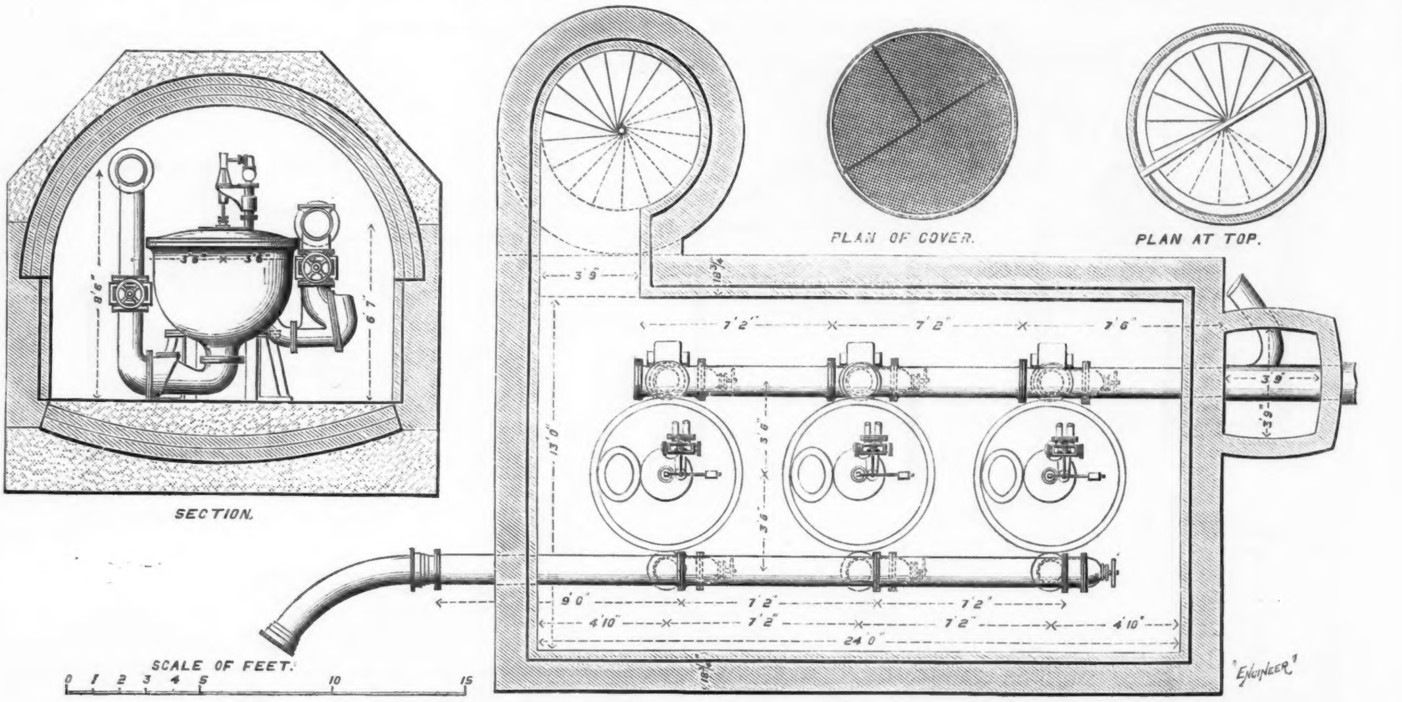
# TEDDINGTON SEWAGE WORKS—SHONE'S EJECTORS



each pair of pumps is driven by a pinion and spur-wheel, any pair can be set in motion by simply throwing a clutch into gear with the pinion. The hollow type of pump is admirably adapted to sewage work. The plunger in this case forms, as it were, a part of the straight run of pipe. There are no pockets or corners in which the thick matter can lodge, and a great feature is that of the patent removable valves or seats, as in a few minutes both valves and seats can be renewed by spare ones, and the damaged valves, or seats replaced at leisure.

The air compressors for working the "Shone" ejectors are by Messrs. Hughes and Lancaster. They are of the horizontal type, working up to an air pressure of 14 lb., the ejectors being distant about one mile. These are in duplicate and are coupled, the cut-off being so arranged that they work automatically. The sludge pressing machinery is by Messrs. S. H. Johnson and Co., and consists of two presses, the sludge being forced into them by direct-acting sludge pumps. We understand that the plant is working very satisfactorily.

## AMERICAN ENGINEERING NEWS.

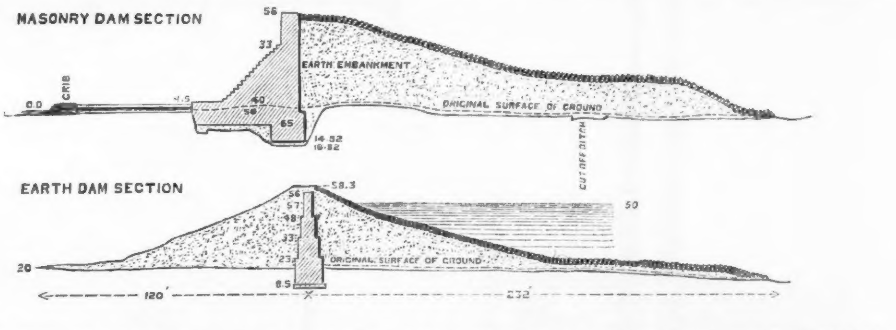
(*From our own Correspondent.*)

*Large pumping engines.*—The Philadelphia waterworks have now what are said to be the two largest waterworks pumping engines in the world, each having a capacity of 30,000,000 gallons in twenty-four hours. They are vertical inverted triple-expansion engines of the marine type, with steam cylinders 36in., 62½in., and 92in. diameter, pump plungers 30in. diameter, and all of 5ft. stroke. The pumps have double-acting, outside-packed plungers, and the pump chambers are directly under the engine. When running at their rated capacity the engines will make twenty revolutions per minute, equivalent to a piston speed of 200ft., and they are guaranteed to show a duty of 125,000,000 foot-pounds for 1,000,000 heat units in the steam received. They work against 145ft. head, and carry a pressure of 140 lb. at the throttle valve. The suction and force mains are 4ft. diameter. Each engine has two shafts, the inward crank arms being connected by a crank pin for the intermediate cylinder. The shafts are 19in. diameter, with bearings 17½in. and 27in. Each engine has two fly-wheels, 19ft. diameter and 30 tons weight. The steam valves are of the Corliss type, and the valve gear admits of the cut-off being set as desired, and also being adjusted independently for the cut-off in each cylinder. The pump valves are circular rubber flap valves. The volume of the low-pressure cylinder is about six and a-half times that of the high-pressure, and the steam is expanded from eighteen to twenty-five times its initial volume in its passage through the cylinders. All the steam cylinders have steam jackets, and are clothed with non-conducting material and polished wood lagging.

*Road improvements.*—Road conventions are now the order of the day, and several States have already held them, the object being the discussion of ways and means for the efficient and economical improvement of country roads. Some harm has been done by a too enthusiastic advocacy of macadamised roads, the cost of which is entirely out of reach of many small communities, but engineers who take the economics of engineering into consideration—and these are not as numerous as could be wished—are bringing out the improvements which may be made at smaller expense on the present roads, especially in matters of maintenance and repair. Some Southern States are trying the experiment of working their convicts on the roads, with good results. One county in Virginia began this in 1892, the first work being on specially hard sections of road, and later more systematic work has been undertaken. The number of men is small—taken from the State penitentiary and the county and town jails—and about three miles per month are covered, the total cost being from 100 dols. to 125 dols. per mile, or 4000 dols. a year in all. The farmers approve it, as it saves the time of their men, and the convicts cost only 35 cents a day to keep—less than half the price for free labour. It has stopped the practice of tramps getting themselves arrested to live comfortably for a few weeks as vagrants, as these tramps do not like the idea of being made to work on the roads. In a few years this county will have an excellent system of highways, the cost of maintenance of which is estimated at 1000 dols. a year. A jail wagon for sleeping purposes is provided, so that the men can do a full day's work.

*Cableway for sewer trenches.*—The Carson and Lidgerwood cableway is designed for use in the excavation of sewer trenches, and reduces the width of street obstructed to a minimum. It is a combined hoisting and conveying device, with buckets suspended from carriers running on a fixed cable, the ends of which pass over two trestle frames and are firmly anchored. The travellers are controlled by an endless travelling wire cable, and a separate cable is used for hoisting and lowering. The engine and boiler are placed on a car at the head of the excavation. The trestles are from 200ft. to 300ft. apart, and 200ft. of sewer can be finished at each setting. The capacity varies according to the size of the buckets and the material excavated, being in several from 200 to 500 cubic yards in ten hours. The cableway can hoist 5000 lb. at a speed of 225ft. per minute, and convey the same at a speed of 450ft. per minute. The material excavated can be run back and dumped as backfilling on the completed work, or can be dumped into carts. Scrapers can be operated as well as buckets. In working a trench 18ft. wide and 15ft. deep, for a sewer 11½ft. diameter, the cost for picking, shovelling into buckets, hoisting, conveying 150ft., and dumping into wagons was 16 cents per cubic yard, the cost for hoisting, conveying and dumping being 5·3 cents per cubic yard. The machines have been used on about twenty contracts, and some cities have purchased them for doing their own sewer work. The carrying and fall-rope devices are on the Locke and Miller patents' as used on other cableways.

*The Dunning Dam.*—At the meeting of the American Society of Civil Engineers, on October 17th, Mr. E. S. Gould described the construction of the Dunning Dam, for a water supply reservoir for Scranton, Pa., built in 1888. At the site selected sandrock crops out on the southerly side, and continues to about the middle of the stream, where it breaks abruptly off. The remainder of the bed on the opposite side being mostly a stiff clay, the dam had to be built half on rock and half on earth, the transition point occurring near the centre of the spillway. The spillway, or wasteway, is 152½ft. long, and its top is 5ft. below the crest of the dam. On the rock is a masonry dam, faced with an earth bank on the inside. Beyond there is a masonry wall with earth banks on both inside and outside. The masonry was backed up to its full height by a heavy bank of earth; in other words, the inside embankment is continuous over the entire length of the dam, so in one sense it is an earth dam with masonry spillway, &c. The engineer strongly favours earth backing for all masonry dams. The sloping front of the spillway was stepped, rather than curved or battered, as this is cheaper and prevents the water from obtaining a high velocity by sweeping over an unobstructed surface. The spillway, during construction, was repeatedly swept by floods. The effect was to excavate the bottom of the stream more or less in front of the dam. In constructing it, a timber crib filled with stone was placed at its lower limit. The bottom of the stream was levelled up with dry stone, the largest obtainable ones placed regularly on top. The joints were packed with spalls, and then a continuous bed of concrete about 1ft. in thickness spread over the dry stone. On top of the concrete a stone masonry pavement was placed. A 48in. cast iron pipe was built in the masonry of the dam as low down as possible, provided with two horizontal gates. This pipe is supported in solid masonry blocks throughout its entire length, reaching from side to side of the pipe gallery, with holes to drain off any water which may accumulate. Over this is a 36in. pipe. This also has two gates, and is supported by the same blocks of masonry. Of the two gates on each pipe, the inner one is to be kept open, or partially open always, and the water turned on or off by means of the lower or down-stream one. No trouble arose in the 1200ft. wall, except at one point, where a crack was open about ⅛in. wide at the top, apparently running out to nothing further down. The leakage was partially stopped by the use of sand, cement, sawdust, &c. The engineer believes that this crack was due to contraction. There was very considerable leakage through the wall of the upper gate chamber, due to the fact that the tower had not been raked and pointed. Hay seed, sand, sawdust, &c., was thrown into the tower, and the leakage was finally overcome. The engineer believes that it is not wise to immediately rake and point the joints of hydraulic masonry, or cover it with plaster, but thinks that it is better to turn the water on first, and see how tight the wall is, and to point and plaster afterwards. In clearing the reservoir site, all trees and stumps were cut as closely to the ground as possible, and the site of the embankment thoroughly grubbed and all sods removed, and the material ploughed up before placing the embankment upon it. The embankment was placed in layers as far as possible. The material was taken out with a shovel or excavator, carried to the foot of the bank in cars, and scraped into place by a scraper drawn by horses, also by wagons in the ordinary way. It was sprinkled while being put in, and the travel of the teams, men, and scrapers was sufficient to compact it. The material was mostly clay and gravel loam. The stone used was mostly conglomerate. Perfect bedding and jointing of all stone with compact mortar was insisted upon, and at the beginning of the work stones were frequently raised, after being bedded, to see that all portions of their beds were in close contact with the mortar. In thick walls all beds were kept swimming. Concrete was mixed ordinarily 1, 2, and 5, but where there was running water to contend with a richer mixture was used.



*American Institute of Mining Engineers.*—The autumn meeting was held at Blackrock, near Bridgeport, Conn., in October. The first papers presented were one on "A Uniform Method for the Assay of Copper Materials for Gold and Silver," by Albert R. Ledoux, and another on "The Inaccuracy of the Commercial Assay for Silver and of Metallurgical Statistics in Silver Mills, with special reference to the Treatment of Roasted Ores by Amalgamation and by the Russell Process," by C. A. Stetefeldt. The purpose of the latter was to show that the reports of managers of silver mills in regard to the percentage of silver saved are far from being the truth. There was also some discussion on the effect of coal dust in mine explosions, which led to some remarks as to dust explosions in flour, sugar, and saw mills. Dr. R. W. Raymond, secretary of the Institute, read a paper on "The New Mining Law of New York," showing the injustice to landowners which the new law effects, amounting almost to confiscation of property. The discussion on the question, "Does the Vibration of Stamp Stems change their Molecular Structure?" turned on the general question of molecular change of metal due to vibration or continual shock. One member said that he was still unsatisfied, but inclined to believe that the stems do crystallise, and that molecular disintegration is going on all the time, even though the change in structure may not be visible. Other members recorded the fact that broken stems show a crystalline fracture, and in one case bars which lasted only about six months were made to last over two years by reversing them occasionally. Another member said that in connection with a legal case involving the failure of a screw shaft, he took a good car axle and broke it slowly under a steam hammer, developing a fibrous fracture. He then broke it in another part by one heavy blow, and the result was a crystalline fracture. Dr. Raymond said that it cannot be that the molecules move around and change from a fibrous to a crystalline arrangement, but that they are either pulled out or broken short off according to the way in which the bar is broken. Mr. Kirchoff said that the ends of broken staybolts from an exploded boiler showed a crystalline fracture, but tests of the bolts showed them to be of good, tough metal. Mr. J. F. Kemp read a paper on "The Nickel Mine at Lancaster Gap, Pa.," which is practically the only productive nickel mine in the United States which has been developed, although discoveries have been made in New York, Oregon, &c. The Pennsylvania ore is pyrrhotite and chalcopyrite, like that of Norway and of Sudbury in Canada. The rock is marked through and through with mundic, and is very hornblendic in structure. It contains about 1 per cent. nickel, some copper, and a little gold. The deepest workings are 250ft. deep. The mine was worked until February last, but it is said to be now full of water. The nickel deposits at Riddles, Ore., resemble those of New Caledonia. Besides the reading and discussion of papers there was an excursion by special train to Ansonia and Waterbury to visit several of the machine works, and the numerous brass and copper mills. At the Benedict and Burnham works, a plant for making copper and brass tubes up to 12in. diameter by the Mannesmann rolling process is being put in.

Another day was spent in visiting the works at Bridgport, and taking a steamer trip on the Sound. On the closing day the party went to New Haven, and visited the numerous buildings of Yale College.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE feature of most importance during the week relates to the progress of the proposed new Galvanised Iron Trade Association to which I have previously referred. The project is assuming proportions which show it to be one of the most complete and far-reaching ever proposed in this department of the iron trade. It will be all-England in its scope, but at the same time the Midlands will have the chief interest in it, since out of an aggregate of some thirty firms engaged in the industry the kingdom over, some twenty-two or more are situated in Warwickshire and Staffordshire. Of the remaining firms, about three are in the West of England, two in Scotland, and two or three in Lancashire. The committee of the combination are being advised by Mr. E. J. Smith, of Messrs. Hoyland, Smith, and Co., bedstead manufacturers, Birmingham, and chairman of the Birmingham bedstead trade. He was the founder of a similar combination which has worked successfully in the English metallic bedstead trade. An important point about the undertaking is that the combination will embrace not only the makers and sellers of the finished sheets but also the makers of the black sheets and spelter, and also the workmen employed at the galvanising establishments.

Finished iron prices remain much the same as last week, with a fairly steady demand, but pigs are weaker. Northamptons are down to 40s.; Derbyshires 40s. to 41s., less 2½ per cent; and Lincolns, 41s. net.

Some difficulty continues to be experienced with reference to the change in proprietorship of the Round Oak Works, which, it will be remembered, passed some time ago out of Lord Dudley's hands into the possession of a company known as "The Earl of Dudley's Iron and Steel Works, Limited." But as the new steel works have been started and are in operation, it is understood that the difficulties are to some extent formal and temporary, and that matters will right themselves in a short time. A private meeting of the company's creditors was held this week. It was announced as far back as July that, under the new scheme for the resuscitated company, £20,000 would be found by Lord Dudley, and £20,000 would be paid under certain conditions by the shareholders. It was hoped that this combined amount would enable the creditors to be paid the sum they had previously agreed to accept, namely, 10s. in the pound, and 10s. in debentures. It seems, however, that a hitch has now occurred. It is stated that out of about £12,000 liabilities, £3000 is due to the Earl. His debentures and first mortgages also swamp the whole of the assets, and the creditors appear to be entirely dependant upon his generosity. A further meeting is to be held. Meanwhile, operations are proceeding quite as usual, and seem likely to continue to do so.

A new departure in cycle engineering, involving the use of machinery different in some respects from that hitherto in use in this industry, has been made by the Jointless Rim Company, at its new works at Long Acre, Aston. The process is patented by Mr. C. H. Pugh, of Birmingham, who is also one of the directors. The rim is a steel tubular structure, and can be made of any section to suit any kind of tire. It is produced from a flat sheet of steel. The sheet is first cut to a circular form, and is next placed under a powerful stamping press, which converts it into a dish-like shape with an upturned and also outwardly turned margin. The centre of the dish is next cut away, and the upturned margin is left to be converted into the cycle rim. The bottom edge is next turned by a metal-spinning process into the same form as the one produced by stamping. Further stages of spinning against blocks of different patterns give the form necessary for the inner side of various sections. A moulded band is next sprung into this groove to form the tread, after which the two outward edges are folded over it, spinning machines being again used for this purpose. The entire process is carried out in cold metal.

Experiments with steel sheets have led so far to the adoption of Siemens-Martin metal—rolled, however, unfortunately, not in this district but in Wales. The treatment to which it is subjected developes the original undefined grain into a continuous interlocked grain of firm spring temper. It is claimed that rims produced by this process are sufficiently strong to bear the weight of a man standing upon them. The absolute truth in circularity obviates unequal screwing up of spokes, such as is necessary with some rims of the customary jointed type. Moreover, there is alleged to be no weak point, as is sometimes the case through the brazing of joints.

Works extensions are in progress at the well-known Beeston premises of the Humber Cycle Co. The concern has been able to extend its connections both on the Continent and in the Colonies during the past season, and in France they have done exceptionally well. The financial year just closed has been the most successful one in the concern's history, enabling the declaration of dividends which are equal to 12½ per cent. for the whole year. The total reserve fund stands at £45,000.

Birmingham manufacturers are hoping that subscriptions to the new Chinese war loan will continue to come in well. The last Chinese loan issued some years ago was subscribed eleven times over. China is spending money freely in the Midlands.

The war in the East is indeed making the Birmingham gun and ammunition trade just now more busy than for many years past. Since the outbreak as many as 150,000 guns are believed to have been exported to the East by a roundabout route, being consigned first to South Africa, and then trans-shipped, according to arrangement, in mid-ocean. Some of these were, however, antiquated weapons which were used in the Franco-German war by the two countries then engaged. They were bought up at that time at a low price from the German Government by a Birmingham firm, who have spent a good deal of money in effectual attempts to modernise them, and are now glad to get them off their hands. It would be amusing to know whether the Chinamen or Japs imagine they are using the latest English inventions in this line.

Negotiations are also reported for another consignment of 20,000 rifles and bayonets, and the number of military cartridges turned out in Birmingham during the past two months is estimated at the enormous aggregate of over ten millions.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester*.—The position as regards the engineering and iron trades of this district remains about stationary. The usual monthly returns of the engineering trades union societies with reference to out-of-work members are not yet completed, but so far as they have come to hand they show no material change either one way or another, and much the same applies to reports which I obtain from representatives of engineering firms as to the position of the leading establishments throughout the district. Taking the bulk of the engineering works, they may be said to be moderately off for orders which just keep them going, with here and there establishments under special conditions fairly busy. It is, however, for the most part only a hand-to-mouth sort of trade that is doing, and the more encouraging reports that I came across a week or two back do not seem to have been followed up by increased activity to any appreciably general extent; a great many works in the district continue extremely slack, and the outlook for the future is still anything but satisfactory. In the iron market there is still only a slow dragging business, whilst in the coal trade complaints from not a few quarters are made that it has not been worse for a number of years past.

The Manchester Iron Exchange on Tuesday was fairly well attended, but only a very limited inquiry was reported generally. The reports from Glasgow and Middlesbrough showing a decided hardening in warrants, necessarily tended in some measure to give rather more confidence, and sellers of outside brands were stiffer in their prices compared with those they would have taken last week; but as regards local and district brands there is no improvement whatever, the tendency in some instances being rather downward than otherwise. Lancashire pig iron makers still report practically no business of any weight coming forward; their quotations of about 39s. 6d. for forge to 42s. for foundry, less 2½ at the works, are little more than nominal in face of the much lower prices at which district brands can be bought, and it is only where local makers have specially favourable rates of carriage that they are booking occasional orders. In district brands also there is little or no business of any moment being put through. Lincolnshire remains fairly steady at the quotations of last week, forge averaging 38s. 6d., and foundry about 40s., net cash, delivered Manchester; but Derbyshire foundry brands have had to ease down so far as the maximum quotations are concerned, and delivered in the Manchester district prices now range from about 43s. 6d. and 44s. to about 45s. and 45s. 3d. net cash. Moderate inquiries have been coming upon the market for outside brands, and sellers of Middlesbrough have been able to get slightly better prices, good foundry qualities being scarcely obtainable under 44s. 6d. to 44s. 9d. net cash, delivered Manchester. In Scotch iron also sellers have stiffened up in their prices, Eglinton not being quoted under 47s. 6d., and Gartsherrie about 50s. 6d. net prompt cash, delivered at the Lancashire ports.

The finished iron trade remains without any improvement, new business still coming forward only in very small quantities, which scarcely keeps forges going more than about four days per week, and although makers quote late rates concessions here and there are made to secure orders. Delivered in this district, Lancashire and North Staffordshire bars range from £5 6s. 3d. and £5 7s. 6d. to £5 10s.; Lancashire and Staffordshire sheets, £7 to £7 5s.; and Lancashire hoops, £5 17s. 6d. for random and £6 2s. 6d. for special cut lengths.

Only a very quiet business continues to be reported in the steel trade as regards either raw or manufactured material. For good ordinary foundry hematites quotations remain at about 52s. 6d., less 2½, for ordinary basic billets £4 net cash; ordinary steel bars are readily obtainable at £6, and steel boiler plates at about £6 2s. 6d. to £6 5s., delivered in this district.

In the metal market list quotations for manufactured goods remain unchanged, and buyers who have been holding back in the expectation of some reduction are giving out orders, perhaps, rather more freely, but there is still only a very small business doing generally.

An excellent and novel arrangement of pillar heat radiators for public buildings, where economy of floor space is a matter of importance, has been designed for the Manchester Corn Exchange by Mr. A. H. Roylance, mechanical engineer. The pillar heat radiators of the ordinary type are not only frequently somewhat unsightly objects, but occupy a very considerable amount of floor space surrounding the pillars. The heat radiators designed by Mr. Roylance are, however, so constructed that the circulating heating pipes are practically worked into the design of the pillar, and made to correspond with the ornamental features in such a way that they form no obstruction whatever, and, in fact, are rather an embellishment than otherwise to the base of the column. Twenty-five heat radiators of this type are being constructed round the base of the supporting pillars in the large hall of the Corn Exchange, each radiator having fourteen double-circulating tubes, with a total heating surface of upwards of 50ft. The diameter of the pillars themselves is 11in., and the outside diameter of the radiators—which is scarcely 18in.—does not project beyond the ornamental cap surmounting the base of the pillar, the heating tubes being so arranged that they correspond with the flutings in the upper portion of the pillar, and in this way are no disfigurement of the base, but have really the appearance of forming a portion of the original design of the column. To economise further the floor space, these radiators are so constructed that the foot of the column for a distance of 12in. from the floor is left perfectly clear, thus providing ample toe space—the radiators, in fact, not occupying any portion whatever of the floor.

Depression prevails all through the coal trade, and even the better qualities still meet with but slow inquiry for house-fire purposes, which, only in exceptional cases, is keeping pits running more than about four days per week, and with plentiful supplies in the market prices are barely maintained at late rates. It is difficult to get more than 11s. for the best Wigan Arley; second qualities of Arley and Pemberton four-feet are offered at 9s. 6d. to 10s., and commoner qualities of house coals can be bought freely at 7s. 6d. to 8s. per ton at the pit mouth. With regard to common round coal for ironmaking, steam, and general manufacturing purposes, the demand is still of a very limited character, and prices, as I have previously anticipated, extend downwards, common steam and forge coal being obtainable at as low as 6s. 6d. to 7s. per ton at the pit mouth. Engine classes of fuel continue a complete drug upon the market, with all sorts of prices taken to effect clearance sales of surplus supplies. Common Lancashire slack can be bought readily at 3s. to 3s. 6d., with best qualities quoted at 5s. to 5s. 6d. per ton at the pit mouth — with slack from other districts offered from as low as 1s. 6d. per ton at the pit — and in the Manchester district the leading colliery firms who have been selling at under their list rates to meet outside competition, have this month formally brought their list rates down to what have previously been their selling price in most cases.

In the shipping trade the position is also quite as unsatisfactory and common round coals can be bought at from 8s. to 8s. 6d. per ton, with better qualities quoted at 9s. per ton, delivered at the Garston Docks, or at the High Level, Liverpool.

In view of the extremely discouraging outlook of the coal trade some very gloomy predictions are here and there made as to the possibilities in the future, especially under the conditions to which the coalowners have agreed with regard to the rate of wages for the next couple of years. The result of this agreement, it is predicted, will be that a number of collieries may in all probability have to be stopped altogether, unless there is some substantial improvement in the condition of trade, especially as the Scotch coalowners, having beaten the men on the wages question, will be in the position of being able to drive Lancashire coal out of some of the important markets, whilst Lancashire coalowners being unable to touch wages will have either to sell at a loss or stop their pits altogether.

*Barrow*.—There is still a very weak market in hematite pig iron. Makers are quoting 44s. 6d. to 45s. 6d. for mixed Bessemer numbers, f.o.b., usual West Coast ports, but they report that business is very quiet all round, and that the disposition to buy forward is exceedingly small. Most of the few contracts entered into are on prompt account. Only thirty-three furnaces are in blast, compared with thirty-four in the corresponding week of last year. Stocks still represent 158,450 tons in warrant stores, being an increase of 63,827 tons since the beginning of the year. A few transactions are noted this week in warrant iron at 43s. 9½d. cash sellers, and 43s. 8½d. buyers.

Iron ore is a very quiet industry. Sales are few on local account, and only a small tonnage is being sent away either by rail or by shipping. Prices remain unchanged at 8s. 6d. for ordinary to 13s. 6d. for best, net at mines.

Steel makers are not so busy as they have been. Last week Cammell's works in Cumberland were stopped, and this week the Barrow works are at a standstill except the steel-casting department. Orders for rails are very quiet. There is a fairly good inquiry in the market for Indian State Railways. The plate trade is not so brisk as it has been, but some new orders are expected as well as on local as on general account. Tin-plate bars are in rather better inquiry. Billets and hoops are quiet. Slabs, wire rods, and blooms are quiet.

Shipbuilders are hopeful of new work, although very few inquiries for new tonnage are in the market. Considerable activity is maintained in makers' yards, and in the engineering and boiler shops things are very busy indeed.

Much progress has lately been made in the steel barrel-making industry at Barrow, and it is expected a good trade will be built up in this department.

The Kellner Partington Paper Pulp Company, which has just declared a dividend of 7 per cent. for the year, is now producing 120 tons of finished high - class paper per week at its Barrow Works, and in addition to this it produces about 50 tons of pulp, which is sold to paper makers in other districts. The directors speak very hopefully of the success of this concern in the future.

Shipping is still quiet. During the week 5255 tons of pig iron and 5990 tons of steel were shipped from West Coast ports, compared with 5275 tons of pig iron and 7375 tons of steel in the corresponding week of last year, a decrease of 20 tons of the former and 1385 tons of the latter. The aggregate shipments to date this year represent 301,515 tons of pig iron, and 342,084 tons of steel, compared with 234,208 tons of pig iron, and 404,570 tons of steel in the corresponding period of last year, an increase of 67,307 tons of pig iron, and a decrease of 62,426 tons of steel on the year.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE market has been somewhat more lively this week than it has been for some time past, but the improvement has been confined entirely to the demand for Cleveland foundry pig and warrants, and has been very short-lived, for a considerable part of the recent advance has already been lost. Still, a fair amount of business has been done at better prices, and less pressure to sell is reported, and holders of warrants are more disposed to keep them, so that they compete less with makers' iron than usual. The market has been influenced partly by the more encouraging commercial news from abroad, more particularly from the United States, where there are more encouraging signs, demand being larger, and failures fewer. Then foreign political reports are much less disquieting. Another favourable influence has been the October statistics of the Cleveland Ironmasters' Association; these were certainly not good for the time of the year, but are less unsatisfactory than had been predicted. In October, which should be one of the briskest shipping months of the year, seeing that it is the last in which cargoes can be sent to some important markets, a considerable decrease in stocks should be reported, whereas this year an increase of 4689 tons was reported in Cleveland iron, and there has been an increase in every month since June, which are just the months when there should be decreases. Still, last month's increase of stock was not nearly as large as had been looked for, and this helped the market up a little.

A considerable quantity of Cleveland foundry pig iron has been sold this week, and not only did the demand for prompt iron increase, but endeavours were made to purchase for delivery over the first quarter of next year, the buyers offering 36s. for No. 3. This was accepted in an odd case or two. It has been paid regularly this week for prompt deliveries, this quality being extremely scarce, and both makers and merchants have not been accepting less. Cleveland warrants have been up to 36s. 0½d. cash, that being 6½d. above the recent lowest, and the best price that has been ruling since the latter part of July, but the advance has not been maintained, and at Wednesday's close the figure was 35s. 9d. cash. The stock of Cleveland pig iron in Connal's warrant stores on 7th was 88,859 tons, or 228 tons increase for the month. Last month there was a decrease of 1114 tons, but the stock of hematite pig iron stocked with them increased 7890 tons, raising the total quantity of hematite with them to 70,657 tons, there having been an increase reported each month for a considerable time past. Grey forge pig iron has been a drug upon the market for the last two months, the furnaces producing more than usual, while the demand has fallen off, owing to the poor condition of the finished iron trade. On this account it is relatively much cheaper than No. 3. Under normal conditions it is only 1s. per ton cheaper, now it is 2s. 6d., and cannot be produced at a profit. In the early part of the year it was quite as dear as No. 3, but then the supply was short. Now any quantity can be bought at 33s. 9d. per ton, and there has been some business at threepence less than this. The make of hematite pig iron continues in excess of the requirements, and the stocks are increasing, though to what extent cannot be said, as the ironmasters do not issue any record of their stock of hematite pig, similar to that given with respect to Cleveland iron. There must now be a large stock, but no move is made towards reducing the production, and the prospects of improvement are not very encouraging. The hematite makers have recently had to reduce their quotations 3s. 3d. per ton, whereas the cost of materials has been but very slightly reduced. The producers of Cleveland pigs have the advantage of those making hematite, as their price of No. 3 has only declined 6d., and where hematite pig used to be 10s. dearer than Cleveland No. 3, it is now only 7s. Foreign ore is dearer.

The Cleveland Ironmasters' October statistics show that out of 141 furnaces erected in the North of England, 95 were in operation at the end of the month, of which 51 were producing Cleveland iron, and 44 hematite, basic, and spiegel iron, no change having been made during the month. A year ago only 85 furnaces were working. The total production of pig iron was 262,309 tons, or 10,038 tons increase on September. Of this 126,628 tons was ordinary Cleveland iron —increase, 4270 tons—and 135,681 tons hematite, spiegel and basic pig—increase, 5768 tons; the increases being due in great part to October being the longer month. Makers' unsold stock of Cleveland pig amounted at 31st to 100,967 tons—increase, 4762 tons; in makers' stores, 2626 tons were held—94 tons decrease; in the North-Eastern Railway Company's warrant stores, 4650 tons—increase, 1135 tons; and in Connal's, 88,631 tons—decrease, 1114 tons; the total stock being thus 196,874 tons, and the increase 4689 tons. The pig iron shipments from the Tees amounted to 80,253 tons; increase on September, 1894, 114 tons, and decrease on October last year 15,420 tons, there being a large decrease in the oversea business, which only reached 44,471 tons, against 56,419 tons last year. About five-sixths of the exports of pig iron were ordinary Cleveland.

The Corporation of Middlesbrough have resolved to honour Sir Lowthian Bell, Bart., F.R.S., by conferring upon him the freedom of the borough in recognition of the eminent services he has rendered to the town. At the meeting at which this resolution was carried it was reported that Sir Lowthian was conducting experiments with a view to eliminating at a cheaper cost than at present the phosphorus in Cleveland iron, so that the best steel can be made from it, and at a cost which will enable it to compete successfully with hematite steel for all purposes. His firm have spent nearly £50,000 in this work. It has also been decided to confer the freedom of the borough on his son, Mr. Hugh Bell.

Steel and iron manufacturers find trade very quite, and profit is out of the question at present prices, but competition is extremely keen, and nothing better can be secured. Bar iron producers maintain their position better than any others, and have for a long time kept the price of common bars at £4 17s. 6d., less 2½ per cent., f.o.t., but even they cannot run their mills regularly. Steel ship plates are quoted at £4 15s., less 2½ per cent., f.o.t., but can be bought at less, but iron ship plates are not below that figure; iron angles are about £4 12s. 6d., less 2½ per cent, f.o.t.; heavy steel rails are offered at £3 12s. 6d. net at works.

Shipbuilders find trade a little better, and a few more orders are secured, chiefly from those who run regular lines of steamers, and are taking advantage of the low prices to get vessels which they will need. Freights are improving a little, and that will influence people to give out more orders. The Tyne Steam Shipping Company has ordered a steamer of 800 tons deadweight to replace the Grenadier, which was lost recently. The vessel will be built by Messrs. Wigham, Richardson, and Co., Walker. Some orders for vessels for the Russian volunteer fleet are also expected. Engineers are also ordering more. The North-Eastern Marine Engineering Company, Wallsend-on-Tyne, has received an order for the machinery for a large steamer for a Liverpool firm, and also one to alter the machinery of a large Spanish mail steamer, converting the existing machinery into the tri-compound system.

Among the mayors for the ensuing year is Mr. Charles Arthur Head, one of the managing directors of Messrs. Head, Wrightson, and Co., Teesdale Iron and Engineering Works, Thornaby-on-Tees. He will be the second mayor of that borough, succeeding Mr. William Anderson, who is the other managing director of the same firm. Mr. William Whitwell, of the Thornaby Ironworks, Thornaby, has been appointed a deputy-lieutenant for the North Riding of Yorkshire.

Prices of coal are fairly well maintained, and the demand is good, though it is tapering off for steam coal, as is usual at this time of the year. At the Ashington Colliery, Northumberland, Messrs. Ernest Scott and Mountain, of Gateshead, are to lay down a dynamo to run 1000 incandescent lamps of 16-candle power, and the Horton Coal Company has ordered from them a similar dynamo for lighting its Whitburn Colliery. At West Hartlepool Dock the North-Eastern Railway Company has completed the erection of a hydraulic coal drop for bunkering large steamers. The new lift is capable of raising a wagon 34ft. above the level of the staith, which is 12ft. from the ground.

### THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE general outlook in the coalfield is somewhat unpromising. Buyers are disposed to show unwillingness to enter into fresh contracts. On account of the mild weather which is at present prevailing, and the conclusion of the Scotch strike, trade on the whole is in an unsatisfactory condition. The dispute with the enginemen has been settled in such a way that each owner has now to privately deal with his own men, and in very difficult cases deputations from the masters and the men will be formed to arbitrate. The men are quite expecting that the owners will at once give them the terms they require. The outcome of this agreement is being looked for with interest by the large body of surfacemen, on whose behalf a new association has recently been formed. There is not much doing in household fuel, owing, as previously stated, to the mild weather. Merchants have laid in large stocks in anticipation of the advance in prices for the winter, but very little buying is at present going on. Although the tonnage forwarded to the metropolis is not up to the usual standard, even the present consignments are blocking the rails, and have to be sold at a reduction to clear off the stocks. The attempt to levy an advance has entirely failed, and some of the agents report that in many cases it is even difficult to keep up summer prices. Quotations, however, remain practically the same, and are as follows: Silkstone house coal, 9s. 6d. to 11s. per ton.; Barnsley house, 8s. 6d. to 9s. 6d. per ton; other qualities from 8s. per ton. Not so much is doing in steam coal, owing both to the advancing season and the fact that more North-country coal has been put on the market since the termination of the Scotch strike. The tonnage sent to the Humber ports is not so large, and stocks are reported to be waiting for shipment at Hull, Goole, and Beadby. Railway companies are taking a fair average on contract account. Barnsley hards are from 7s. 9d. to 8s. 3d. per ton, inferior sorts from 7s. Gas coal is in good demand at 7s. to 8s. per ton. Manufacturing fuel continues to be in the same depressed state, and it is likely to stop there, according to the reports from the textile districts. Pit slack, 3s. 6d. per ton; screened slack, 4s. 5d. to 5s. 6d. per ton. Smudge and small coal in abundance at low rates. Coke the same as last reported.

The prices of iron and steel continue so low that in many cases the machinery is simply being turned round without leaving any appreciable profit. It is believed that prices have now fairly got to the lowest ebb, and the present rate of colliers' wages will certainly preclude any further decline. Hematites remain at 50s. to 52s. per ton, according to brand, delivered in Sheffield. Common forge iron stands at 38s. per ton. Bessemer billets at £5 7s. 6d., and bar iron, for which there is a very feeble demand, at from £5 5s. upwards. In the latter department manufacturers are still suffering severely from the coal stoppage of last year. It occurred at the time when the colonial market was opening out for bars, and our firms were unable to take the work then offered. There is no expectation of any considerable improvement this side of Christmas.

In the general branches of the heavy steel trade business is decidedly slack, and manufacturers have not much hope now of any animation before next year. Railway material, for which there must be a heavy demand very soon, remains at present, however, in very light request. Extensive railway developments are in progress and projected at home, and there are still further movements in that direction in the great Indian market. In both cases a large amount of work is certain to come to this city. These will mainly be in the production of tires, axles, springs, buffers, and the parts which go to make up the completed locomotive. There is some prospect of a change for the better in shipbuilding material, but at present it is not very pronounced. Although the closing quarter of the year is always looked forward to in the steel trade as the busiest, manufacturers so far have not found it so. The colonial trade is just now setting in, but the Birmingham houses appear to be feeling its benefit more appreciably than in the Sheffield district. A good deal of work which would have naturally come here last season went there while the work was standing, and it will be interesting to know how far it will return. Experience in Sheffield proves that once trade has been displaced there is nothing so difficult to win it back to the old channel.

The armour-plate departments are exceedingly busy. The three firms producing that important class of work are now engaged upon armour for five first-class battleships simultaneously. This is altogether a new experience in the armour-plate establishments. The plates are being turned out with exceptional celerity, and, as the Secretary to the Admiralty admitted last week, to the complete satisfaction of the naval authorities. Another class of military material is in quite a different condition, viz., the manufacture of armour-piercing projectiles. No orders have come to Sheffield for a considerable period, and if it turns out to be true, as reported, that the Government intend to commence making steel shells at Woolwich Arsenal, a large amount of costly machinery and plant will be thrown idle. Sheffield manufacturers feel strongly about this competition of the Government establishments, and hold that it is very unfair, after they have lavishly spent capital upon the best procurable plant, and made many expensive experiments, that they should be refused the orders. It is stated that the Government contemplate a new class of shell, and that they have obtained specimens from Sheffield and elsewhere, which they are testing at Woolwich.

In the larger silver plate and electro establishments overtime is at present being worked, on account of the season orders for Christmas and New Year. The smaller houses, however, are not so well off as they expected to be, the tendency being more and more to concentrate the bulk of the work in the more extensive establishments. A feature of this business is the extraordinary variety of new patterns and styles, their number being the clearest possible proof of the necessity which exists for tempting buyers with novelties, which combine artistic beauty with practical utility.

### NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has exhibited a good deal of animation this week. Scotch warrants have changed hands in comparatively large quantities. Prices advanced 3d. per ton early in the week, and although subsequently there was a reaction, the market continued fairly active. Cleveland iron has followed a similar course as to prices, but business has been restricted. Cumberland hematite has been a little firmer.

The lighting of blast furnaces has continued, and there are now 60 in operation in Scotland, compared with 56 last week and 53 in the corresponding week of last year. There are 12 blowing at Gartsherrie, all on ordinary iron; Coltness has 3 making ordinary and 6 hematite, Dalmellington 3 ordinary and 1 hematite, Shotts 2 ordinary, Eglinton 8 ordinary, Clyde 1 ordinary and 2 hematite, Wishaw 2 ordinary and 1 hematite, Carnbroe 4 ordinary, Calder 1 ordinary and 3 hematite, Govan 3 ordinary and 2 hematite, Summerlee 5 ordinary, and Monkland 1 ordinary. There are thus 45 furnaces producing ordinary, and 15 hematite pig iron, the production of basic pig being as yet neglected.

The balance of makers' special brands remain comparatively steady as follows:—G.M.B. f.o.b. at Glasgow, No. 1, 44s.; No. 3, 42s. 6d.; Monkland, No. 1, 45s. 6d.; No. 3, 42s. 6d.; Carnbroe, No. 1, 46s. 6d.; No. 3, 45s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Calder and Gartsherrie, Nos. 1, 52s. 6d.; Nos. 3, 48s.; Summerlee, No. 1, 53s 6d.; No. 3, 48s.; Coltness, No. 1, 55s. 6d.; No. 3, 50s.; Glengarnock at Ardrossan No. 1, 52s. 6d.; No. 3, 47s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s. Dalmellington, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 58s.; No. 3, 50s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 4313 tons, compared with 3820 in the corresponding week of last year. The 4313 tons were disposed of as follows:—China and Jtpan 650 tons, India 433, Canada 400, Holland 360, South America 150, United States 50, Australia 90, France 43, Germany 270, Belgium 30, Spain 105, other countries 70, the coastwise shipments being 1662 tons, against 1171 in the corresponding week.

The manufactured iron trade recovers but slowly. The capacity of the works in the West of Scotland is such that orders just now available are easily absorbed and executed. Prices are fairly steady, but, as is also the case with those obtained for steel, they are not in the main very remunerative. The mainstay of the steel trade is the shipbuilding industry, which is at present well employed with a number of very good additional orders coming to hand.

The exports of manufactured iron and steel in the past week embraced general machinery worth about £10,000; sewing machines, £14,660; steel goods, £4108; and general iron manufactures, £14,476.

The coal trade continues to expand in volume, the demand for home use is much greater, owing to the large quantities now required for the iron and steel works, and the shipments are likewise increasing, the improvement in the past over the preceding week being 31,444 tons. The increase has arisen chiefly on the East Coast, where the miners are now all at work. Prices continue steady, and for manufacturing purposes they are generally regarded as rather stiff.

### WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

IN a run over a section of the colliery district this week I have been much impressed with the change brought about by the last few weeks of stormy weather. Steamers having been driven back from the ports, or failing absolutely to come in, have led to very partial work at collieries and a thorough congestion of coal traffic. At one colliery I noticed that every siding was blocked with laden coal wagons, and a modified condition of the same state of things was visible in every direction, at collieries and at ports, while in the colliery towns fully half the week has been spent in holiday making.

There was a partial break on Tuesday, but a return of the stormy hindrances on Wednesday, and the week's total coal exports will, I fear, be a small one, comparatively. This has naturally told on prices, especially on steam coal, which remains weak. So far the lowest prices keep at 11s., but there are fears that a drop is likely into the "tens." The last quotations, Cardiff Exchange, were: Best steam, 11s. to 11s. 3d.; seconds, 10s. 3d. to 10s. 6d.; best Monmouthshire, 10s. 3d. to 10s. 6d.; and seconds, 9s. to 9s. 3d.

Small steam has seen a good deal of the up and down character of late. The market has been so glutted that prices dropped below 4s. Midweek there was a slight recovery, and the last quotations were: Ordinary, 4s. to 4s. 3d.; best, 4s. 6d. to 5s.

House coal figures remain much about the same, instead of advancing, as is generally the case at this time of the year. Cardiff quotations this week were:—Best qualities, 10s. 9d. to 11s.; No. 3 Rhondda, 10s. to 10s. 3d.; brush, 8s. 6d.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s. 6d.; through, 6s. 3d. to 6s. 6d.; small, 4s. to 4s. 6d. It is not likely that these figures will remain, and as inland trade is getting stronger, an advance is certain.

Patent fuel is dull, both at Cardiff and Swansea. Cardiff prices, 10s. 9d. to 11s.; Swansea, 10s. to 11s. For coke the demand continues moderate. Latest Cardiff quotations:—Furnace, 14s. to 14s. 6d.; foundry, 15s. to 15s. 6d.; special foundry, 19s. to 20s. At Swansea furnace coke is quoted at 12s. to 12s. 6d., and best foundry 17s. 6d. to 18s., thirty days cash, less 2½.

The iron and steel trades show little change. The large works at Dowlais continue fairly active, though there is little special business in hand, and the sidings on Monday exhibited but a small quantity of steel bar. The busiest department at most of the works from Blaenavon to Ebbw Vale, and thence to Cyfarthfa and Dowlais, was that connected with foreign ore receipts. The aggregate quantity to hand during the week was very large, and, coupled with a little brightening of pig iron prospects, gave some encouraging signs. Prices continue very weak. Cyfarthfa holds its own well, especially in bar.

From an old document, dated 1807, it will be seen what a remarkable decline has taken place in values. Then pig iron was sold at £5 10s., bar was at £16, and a bag of coal at the pit, 8½d.

Swansea quotations this week are as follows:—Pig iron, Glasgow warrants, 42s. 10½d.; hematite warrants, 43s. 9½d.; Middlesbrough, 42s. 7½d.; Welsh bars, £5 2s. 6d.; steel rails, heavy, £3 15s. to £3 17s. 6d.; light, £4 10s. to £4 15s.; sheet iron, £6 to £6 10s.; steel sheets, £6 5s. to £6 10s. Bessemer steel, bars for tin-plate, £4 to £4 2s. 6d. Siemens, best, £4 to £4 2s. 6d.

Tin-plates: Bessemer, 10s. to 10s. 3d.; Siemens, 10s. 3d. to 10s. 6d.; ternes, per double box, 28 by 20 c., 20s. to 22s.; best charcoal, 12s. to 12s. 3d., according to finish of brand. Wasters, 6d. to 1s. less than primes. All delivered Prince of Wales' Dock, Swansea; cash, less 3 and 1 per cent. Block tin is at £66 10s. to £66 12s. 6d. Iron ores, Tafna, 11s.; Rubio, 11s. 3d. to 12s.; 1s. 6d. per ton extra for selected large. Other Swansea quotations this week were lead, English, £10 to £10 2s. 6d.; Spanish, £9 17s. 6d. to £10.

It will be noticed that now that English quotations approach so near to those of foreign, there may be a little more hopefulness for the Welsh mines, many of which have been in a depressed condition for years, owing to foreign rivalry. Aforetime the difference was fully £1 per ton against that of Wales.

The Birmingham influences brought into the Rhayder district may lead to a better development of the lead mines of that neighbourhood.

The outlook of the tin-plate trade has not the roseate appearance one would wish to see, yet I think too gloomy a view is being taken from the fact that wage reductions are imminent, and some works contemplate closing if they are not accepted. There is no denying that stocks are decreasing, and so too is the production. When stocks have fallen to a certain point the crisis will come, and a turn, I confidently think, for the better. The weeding out of a few struggling works would improve the situation, though it is always regrettable to see capital and wasted energies scattered for nought.

One would have thought that a more buoyant tone would have been exhibited on 'Change, Swansea, mid-week, for the stocks were reported as 30,000 boxes less than the corresponding week last year. The shipments last week totalled 97,448 boxes, and the receipts from works 68,240 boxes. Stocks at Swansea now only amount to 202,264 boxes. One of the best tin-plate shipments of the year was that of 3300 tons last week sent by the Minnesota to the United States. Large clearances are expected to take place with arrival of tonnage.

The present time is evidently regarded as a favourable one for bringing house coal collieries to the hammer. In addition to those I have noticed of late as changing hands, I see that the Adare Colliery, Dinas, Rhondda Valley, will be sold early in December. The colliery is situated near the "Naval" Steam Colliery, and the seam worked is No. 2 Rhondda. On the 27th, at the Pyle and Brynda Railway and Cefn Collieries, near Bridgend, the whole of the surplus plant, machinery, and materials will be put up for auction. I note that the surplus includes a number of vertical and horizontal winding engines, two Cornish pumping engines, and a number of coal wagons.

Another illustration of the thoughtlessness of some colliers is being given in the opposition shown in various places to the public benefactors of the country towards the Albion calamity being vested in the Provident Miners' Society. This excellent organisation has done good service for many years, and requires more general support than it gets; and with its matured appliances could distribute well and with extreme economy; but no, the collier wishes to get relief from this fund and the public as well. I am glad this is only a partial opinion of the inconsiderate. The mass of intelligent and thoughtful colliers support the fund.

### NOTES FROM GERMANY.

(*From our own Correspondent.*)

MATERIAL changes have not taken place on the general iron market since last report. Activity in the different departments continues moderate; buying, especially that on foreign account, is still being carried on very cautiously, and there is a general belief that there is not much probability of any improvement taking place until the beginning of next year.

A lifeless tone characterises the Silesian iron industry. There has even been less doing this week than last, and prices are, if possible, a little more depressed than usual. Steel manufacturers are hardly able to keep their mills in regular operation; they meet with the greatest difficulties in securing further orders, even though they willingly agree to prices which scarcely cover the costs of production.

The situation of the Austro-Hungarian iron trade is satisfactory on the whole. Concerning the different branches there has been quite a regular demand experienced for pig iron, and prices show considerable firmness. Common forge pig is sold at 46 fl. p.t.: mixed lots, 47 to 48 fl.; while grey forge stands at 48 to 51 fl. p.t. Bessemer continues to be quoted 49 to 51 fl. p.t. at works. The malleable iron trade is well employed in almost all departments. The requirements of the railway companies, though of small weight generally, will help to keep the mills in fairly good activity for the remainder of the year. Bars are in quiet call at 107·50 to 115 fl. p.t., while girders fetch 106 to 110 fl. p.t. Heavy plates quote 180 fl.; tank do., 135 fl.; galvanised sheets, 215 to 270 fl. p.t. at works. The majority of the wagon and locomotive factories are in a poor condition, and some of them had to dismiss a number of their men.

Output of pit coal in Austria is statistically stated to have been as under:—

| | 1892.<br>100 kgs. | 1893.<br>100 kgs. |
|---|---|---|
| Austrian Silesia | 39,900,531 | 36,935,416 |
| Bohemia | 37,479,977 | 36,887,145 |
| Moravia | 12,672,376 | 11,797,896 |
| Galicia | 6,790,299 | 6,324,794 |
| Lower Austria | 480,220 | 463,869 |
| Styria | 3,106 | 2,141 |
| | 97,326,509 | 92,411,261 |

On the French iron market the tendency of prices is rather less firm than during previous weeks. Orders are coming in but slowly, and there is generally much reserve practised on both sides. Some of the large establishments are very busy at present executing orders of former date, and until these are finished makers do not care so much for new work. A real improvement cannot reasonably be expected before New Year, and even then it is doubtful whether the hopes that are being entertained in some quarters will be realised. Up-to-date production has been about equal to consumption; only for some special sorts of structural iron demand has slackened off lately, and manufacturers accept prices that are a little below list rates.

In Belgium the iron and steel trade has, if anything, gathered further strength in the course of the past week. Pig iron is still to be had at very cheap rates, but in the malleable iron department a fair activity is reported, and there is an undeniably improving tone in the export trade, though the prices offered are, as a rule, too low to allow any profit.

The unfavourable situation of the Rhenish-Westphalian iron industry, which was reported in last week's letter, continues.

On the pig iron market a tolerably firm tendency has hitherto been noticeable as regards quotations, although demand is limited and makers are rather badly off for new work. High prices of coal and high wages in many instances prevent a further going down in quotations, and the fact that prices of pig iron are well maintained may be accounted for by the utter impossibility of further reductions rather than by an improving tendency in trade. The blast furnace works of the Siegerland have been booking a lot of fair orders upon the week, and are for the greater part much better situated than the works of the Westphalian district.

For malleable iron a weak demand is experienced generally; both bars and girders are exceedingly dull, and the depression in prices continues, and in some cases even increases. Hoops have been a trifle more lively, consumers and dealers being, it appears, rather anxious to cover their demand at the ruling low quotations. Plates and sheets are in moderate call, and the business in drawn wire and wire nails moves from bad to worse. Rivets are likewise suffering from the unfavourable condition of the market. The moderate employment in the railway and engineering line continues, and the foundries are also but very indifferently engaged. At the wagon factories, on the other hand, a fairly regular activity is going on.

Figures of French foreign trade published by the Board of Customs were, for September and for the first nine months of present year, as under:—

| Import. | 1894.<br>f. | 1893.<br>f. | Difference.<br>f. |
|---|---|---|---|
| Victuals | 90,840,000 | 86,651,000 | +4,189,000 |
| Raw materials | 159,396 000 | 154,538,000 | +4,858,000 |
| Manufactured goods | 42,164,000 | 43,847,000 | −1,683,000 |
| Totals | 292,400,000 | 285,036,000 | +7,364,000 |

| Export. | 1894.<br>f. | 1893.<br>f. | Difference.<br>f. |
|---|---|---|---|
| Victuals | 54,318,000 | 58,897,000 | −4,579,000 |
| Raw materials | 78,161,000 | 60,619,000 | +12,245,000 |
| Manufactured goods | 110,898,000 | 138,369,000 | −27,471,000 |
| Parcels sent by post | 3,894,000 | 2,915,000 | +979,000 |
| Totals | 242,271,000 | 260,800,000 | 18,826,000 |

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*24th October*, 1894.

20,339. Memorandum Books and Postcards, J. Jensen Essex.
20,340. Machines for Washing Potatoes, J. Burrell, London.
20,341. Broad Silk Pieces, G. C. Franklin, Birmingham.
20,342. Lace Fastening Block, S. Genese, London.
20,343. Photographic Apparatus, A. J. Boult.—(*L. Joux, France.*)
20,344. Map Carrier for Cyclists, W. P. Thompson.—(*M. Tixier and L. Maisounabe, France.*)
20,345. Bottle Stoppers, W. P. Thompson.—(*M. Tixier and L. Maisounabe, France.*)
20,346. Boring Implements, A. Lane and C. E. Lane, London.
20,347. Cleansing Carding Machines, F. X. Zettler, Germany.
20,348. Securing Coats and the like, J. H. Leber, London.
20,349. Stoves, R. Poore, London.
20,350. Supplying Food to Horses, W. D. Farn and T. U. Clarke, London.
20,351. Feed-water Heating Apparatus, J. E. Carroll, London.
20,352. Graduated Measure-stopper for Bottles, L. Wookey, London.
20,353. Inkstands, A. Barker, London.
20,354. Electro-deposition of Aluminium, P. Marino, London.
20,355. Blinds, H. Kent, London.
20,356. Flushing Apparatus, H. Kent, London.
20,357. Clothes Drying Machine, T. Cudlipp, London.
20,358. Photographic Paper, H. H. Lake.—(*Arndt and Trost, Germany.*)
20,359. Waterproof Fabrics, W. Boeddinghaus, jun., London.
20,360. Coin-freed Locks for Doors, J. N. Maskelyne, London.
20,361. Paper Fastener, C. Schwegler, Wiesbaden, Germany.
20,362. Frost Pegs or Cogs for Horseshoes, T. Parish, London.
20,363. Telephone Supports, H. and A. B. Gilbert, London.
20,364. Bicycles, &c., J. S. Taylor and J. V. Pugh, London.
20,365. Recovery of Zinc from Alloys, W. S. Rawson and R. Heathfield, London.
20,366. Controlling or Regulating Machinery, L. Epstein, London.
20,367. Steam Cultivators, A. J. P. de Souza, London.
20,368. Apparatus for Pumping Liquids, L. Gunn, London.
20,369. Keying Railway Rails in their Chairs, A. Mosley, London.
20,370. Hot-water Boilers, &c., E. W. Herendeen, London.
20,371. Window Sashes, The Simplex Window Fittings Company and P. Daw, London.
20,372. Bolts for Windows, F. R. M. Phelps and The Simplex Window Fittings Company, London.
20,373. Production of Zinc Compounds, J. P. Lacy and A. J. Ash, London.
20,374. Stone-grinding Machines, P. R. J. Willis.—(*J. Lavers, United States.*)
20,375. Manufacture of Asphalt, F. X. Byerley, London.
20,376. Manufacturing Rugs, &c., J. Fels.—(*R. Grubb, United States.*)
20,377. Photographic Cameras, J. Wilson, London.
20,378. Bedsteads, F. J. Chubb, London.
20,379. Trucks for Conveyance of Guns, E. R. Hicks, London.
20,380. Sponge Bags, E. Hanisch and C. Adamy, London.
20,381. Pulleys and Brackets for Same, J. Hewitt, London.
20,382. Electric Telephones, A. C. Brown and G. R. Neilson, London.
20,383. Pneumatic Tires, R. R. Gubbins, London.
20,384. Faucet, W. D. King, London.

*25th October*, 1894.

20,385. Cycle Saddles, T. Middlemore and J. Beesley, London.
20,386. Tobacco Pipes of Aluminium, C. G. Jacobsen, London.
20,387. Rope and Chain Wheels, T. Meacock, Stafford.
20,388. Wood-splitting Machines, E. Cory, F. W. Reynolds, and W. C. Catford, London.
20,389. Roundabouts, &c., L. Hibbs and T. Collier, Nottingham.
20,390. Wearing Apparel, J. A. Gregory, Nottingham.
20,391. Keeping Fencing Wires Strained, W. H. Lindsay, Bristol.
20,392. Mud-guard for Cycles, H. Wells, Stockton-on-Tees.
20,393. Dress-guard for Cycles, E. Hall and H. Hall, Leicester.
20,394. Pneumatic Tires, A. Shiels, Glasgow.
20,395. Windows, H. Wilson, Lanarkshire.
20,396. Clothes-horses, H. Ashby, Newcastle-on-Tyne.
20,397. Cutting-out Electric Arc Lamps, H. J. Crefield, Kent.
20,398. Steering Engines, W. E. Moss, Liverpool.
20,399. Gas Burners, A. Bennett, Glasgow.
20,400. Belt Fasteners, J. Oswald, Manchester.
20,401. Pneumatic Tires of Wheels, C. G. Virgo, Manchester.
20,402. Barrel Ratchet for Watches, R. Thorneloe, Birmingham.
20,403. Cigarette and Cigar Cases, M. Blanckensee, Birmingham.
20,404. Barbed Chain or Barbed Fencing, P. A. Martin, Birmingham.
20,405. Nailing Machines, J. Hawley, C. Cooper, and J. Lee, Liverpool.
20,406. Means for Insulating Chambers, M. C. Bannister, Manchester.
20,407. Gully, R. M. Gloyne, Eastbourne.
20,408. Wall Lamps and Brackets, C. Meason, Birmingham.
20,409. Lamps, C. Meason, Birmingham.
20,410. Drawing-boards, J. Crabtree, London.
20,411. Chair-locking Devices, J. Walker, Glasgow.
20,412. Heels for Boots and Shoes, W. Brewster, Manchester.
20,413. Clearing Hook for Anglers, H. Warry, Totnes.
20,414. Making Briquettes for Fuel, R. Fegan, London.
20,415. Gripping Appliances, H. P. Hoghton, Manchester.
20,416. Ruling Apparatus, F. Bardelli, K. Danielovsky, and A. Orszagh, Manchester.
20,417. Golf Clubs, J. Smith, Glasgow.
20,418. Fittings for Window-blinds, T. Sumner, St. Helens.
20,419. Baits, Flies, &c., for Fishing, W. M. James, Redditch.
20,420. Folding Music Stands, J. Berg, Glasgow.
20,421. Buffing-machines, A. and F. H. Pochin and H. Addison, London.
20,422. Manufacture of Steel, W. P. Thompson.—(*E. Bertrand and O. Thiel, Austria.*)
20,423. Printing Colours by One Impression, F. Barnwell, Liverpool.
20,424. Fonts of Lamps, R. O. Jones, Manchester.
20,425. Preparation of Foods, C. H. Biss, Liverpool.
20,426. Double-action Beer Drip Saver, C. J. Herbert, London.
20,427. Bottling-machines, E. Stahl, London.
20,428. Sterilising Milk, F. Guilleaume and E. Goltstein, London.
20,429. Candlestick, A. M. Coleman, Hants.
20,430. Bicycle Lamp, J. Benn, Birmingham.
20,431. Flying Machine, W. Frost, Saundersfoot.
20,432. Electric Bell, F. C. Allsop, London.
20,433. Manufacture of Window Tickets, H. E. Ash, London.
20,434. Protector for Scarf-pins, V. Drew and J. C. Saunders, London.
20,435. Buffers of Railway Wagons, B. Ramsden, London.
20,436. Type-writing Machines, J. T. Armstrong and G. F. Wetherman, London.
20,437. Combined Funnel and Measure, A. G. Luck and H. Mitchell, Sussex.
20,438. Cycle Tires, and Rims, G. T. Frankland, London.
20,439. Electrical Energy, H. Tipping, H. A. Tobias, W. H. Cadman, and R. J. Crowley, London.
20,440. Harrows for Agricultural Purposes, E. Slade, London.
20,441. Staple-making Machinery, B. J. B. Mills.—(*P. C. Oscanyan, United States.*)
20,442. Arc Lamps, J. E. A. Gwynne and R. Kennedy, London.
20,443. Holding Glass Balls for Advertising, J. B. Adams, London.
20,444. Automatic Mechanical Stoker, M. Sonnenschein, London.
20,445. Stopper for Bottles and the like, T. Chanson, London.
20,446. Sinks and other Sanitary Appliances, S. H. Rowley, London.
20,447. Process for Soot Combustion, W. Michalk, London.
20,448. Portable Steps, A. F. Whislay, Brightlingsea, Essex.
20,449. Rotary Hair-brushing Machine, H. Leslie, London.
20,450. Chimney and Ventilating Cowl, L. W. Shedden, London.
20,451. Drills, M. C. Johnson, London.
20,452. Protecting Ladies' Dress Skirts, A. Smith, London.
20,453. Pneumatic Tires, A. James and D. Steffano, London.
20,454. Sunshades, Parasols, and Umbrellas, J. Allcock, London.
20,455. Locomotives, H. Degener and R. Deissler, London.
20,456. Speed Indicators, J. Prokofieff, London.
20,457. Apparatus for Diffusing Scents, R. V. Wagner, London.
20,458. Bandoliers, W. G. Leckie, London.
20,459. Butter Workers, F. T. Gade, London.
20,460. Cycle Gear Cases, W. Bransom, London.
20,461. Propelling Ships, S. Burton, London.
20,462. Induced Current Telegraphy, F. E. W. Bowen, London.
20,463. Pneumatic Tires, S. Lee, London.
20,464. Sliding Sashes, W. A. Bramley, London.
20,465. Armour Plate Manufacture, J. A. Hunter, London.
20,466. Steam Generators, L. E. Solignac, London.
20,467. Egg Supports for Plates, P. W. V. Brooks, London.

*26th October*, 1894.

20,468. Ploughs, J. Hornsby, J. Innocent, and I. Trolley, Grantham.
20,469. Sheaf Binders, J. Hornsby and J. H. Smith, Grantham.
20,470. Word-builder for Teaching Spelling, J. R. Sharpe, Lincoln.
20,471. Fish and Fruit Packing Tins, W. Hodkinson, London.
20,472. Graduating Clawker Apparatus, S. A. Hill, Nottingham.
20,473. Pneumatic Tires, C. Inglefield, Manchester.
20,474. Venetian Window Blind, A. Chenhalls, jun., Cornwall.
20,475. Coin-freed Apparatus, W. Alexander and W. E. Thompson, Birkenhead.
20,476. Hair-curling Pins, J. Hewitt and F. R. Baker, London.
20,477. Springless Latch Lock, J. B. M. Stewart and A. W. King, Sussex.
20,478. System of Announcements, T. H. Rochford, Dublin.
20,479. Carding-engines, E. and S. Tweedale and J. Smalley, Manchester.
20,480. Treatment of Liquids, J. J., T. F. and J. W. Meldrum, Liverpool.
20,481. Rims of Wheels, R. Green, Birmingham.
20,482. Junction Couplings, H. A. Cutmore, London.
20,483. Jointing Stoneware, F. H. Brook, London.
20,484. Carpets, W. C. Gray, Glasgow.
20,485. Condensed Milk Products, W. F. Maclaren, Glasgow.
20,486. Friction Clutches, W. Shore and G. E. Coupe, Manchester.
20,487. Spinning Textile Fibres, R. Todd, Manchester.
20,488. Tyres, J. Watt, Glasgow.
20,489. Infants' Chairs, T. C. Dickie, Glasgow.
20,490. Cycles, P. H. Newill, Salop.
20,491. Cleaning Railway Carriages, J. R. Hazel, Glasgow.
20,492. Pneumatic Harness Pad, W. T. Day, Wolverhampton.
20,493. An Improved Horseshoe, A. Felstead, London.
20,494. Label and Postage Stamp Server, J. R. Kilroe, Dublin.
20,495. Hand Air Pumps, W. Brown, Birmingham.
20,496. Spinning and Doubling Cotton, T. Ashworth, Manchester.
20,497. Jacquard Apparatus, W. and H. A. Fielding, Manchester.
20,498. Wagons, F. Warburton and W. Warburton, Manchester.
20,499. Hoops for Laminated Springs, T. Turton and Sons, Ld., and J. Roberts, Sheffield.
20,500. Drying Clothes, &c., H. C. Longsdon, Keighley.
20,501. The Sanitary Protector, I. Kaufmann, London.
20,502. Firelighter, W. Sander.—(*C. W. Winkelmann, Germany.*)
20,503. Protectors for Watches, G. Stegmann, London.
20,504. Pianoforte Actions, G. D. Rose, London.
20,505. Fire-proof Dwellings, H. W. Butler, London.
20,506. Casing for Hot-water Pipes, J. W. Kitson, London.
20,507. Driving Gear for Cycles, J. S. Miller, London.
20,508. Rims for the Wheels of Cycles, W. H. Taylor, Manchester.
20,509. Increasing the Power of Marine Boilers, J. Hodgkinson, London.
20,510. Cup and Hat Hooks, J. J. James, Birmingham.
20,511. Fittings for Carriage Windows, J. Ingram, London.
20,512. Steam Generators, R. H. Radford, Sheffield.
20,513. Stoppers for Bottles and Jars, R. Hornby, London.
20,514. Water Jacket Tube Boilers, W. T. Allen, London.
20,515. Brackets for Velocipedes, A. J. Edmonds, London.
20,516. Hitching Straps, J. H. Valleau, London.
20,517. Ventilators, F. O. Prince.—(*J. Featon and J. P. G. Martin, New Zealand.*)
20,518. Tires for Road Carriages, H. T. Stephens, London.
20,519. Bearings, F. W. Kitto and W. Haworth, London.
20,520. Combined Umbrella and Stick, I. Keyzor, London.
20,521. Artificial Musk, C. D. Abel.—(*Fabriques de Produits Chimiques de Thann et Mulhouse, Germany.*)
20,522. Friction Clutches, F. W. Golby.—(*M. Kastler, France.*)
20,523. Extracting Pickles from Bottles, W. O. Joseph, London.
20,524. Safety Valve Apparatus, A. Sempell, London.
20,525. Spinning Machines, J. Good, London.
20,526. Closing Openings in Dresses, S. Miller, London.
20,527. Straw-trussing Machines, J. H. and G. Howard and G. Gibbs, London.
20,528. Mitre Cramp, &c., J. and J. Hampton, Ld., London.
20,529. Manufacture of Cigars, J. Reuse, London.
20,530. Lifting-jacks, E. R. Stilwell, London.
20,531. Fastening for Wearing-apparel, C. Smith.—(*S. A. M. Sevin, France.*)
20,532. Addressing Envelopes, &c., F. D. Belknap, London.
20,533. Shuttle-race for Looms, H. H. Lake.—(*L. Scondetti, Italy.*)
20,534. Means of Dissolving Saccharum, A. Young, London.
20,535. Material for Building Purposes, F. Wittmann, London.
20,536. Trivets, W. Coates, London.
20,537. Wheel Tires, H. Carmont, London.
20,538. Hot-air Engines, E. H. Norris and C. G. Henty, London.
20,539. Velocipedes, W. E. Evans.—(*L. Marchand, France.*)
20,540. Covering Walls with Glass, The Ceralite Syndicate, Ld., E. T. Hall, and J. Breeze, London.
20,541. Cradles, J. Abraham, London.
20,542. Packings, J. P. Gauthier, N. Henriot, and A. Tourdanet, London.
20,543. Garment Holders, A. Provost, London.

*27th October*, 1894.

20,544. Holders for Pens, J. Strick, London.
20,545. The Poison Bottle, H. H. Moore, County Cavan.
20,546. Electric Telegraph Systems, S. Butcher, London.
20,547. Moles, J. Grey and W. Taylor, Norden, near Rochdale.
20,548. Electrical Motor Fittings, H. Lea, London.
20,549. Cup for Pie Dishes, M. A. Thomas, London.
20,550. Steam Heating Apparatus, H. M. Wilson.—(*J. Langridge, Japan.*)
20,551. Preparing Cotton, &c., J. W. Bullcck, Wigan.
20,552. Throwers for Book-sewing Machines, A. Logan, London.
20,553. Mackintosh Overcoats and the like, W. Tuley, Halifax.
20,554. Chimney Cowls, G. N. Millward and B. Nicklin, Birmingham.
20,555. Door and other Similar Bolts, B. Nicklin, Birmingham.
20,556. Disinfecting Compounds, C. Gates, Glasgow.
20,557. Furnaces for Heating Steel, W. G. Moore, Banbury.
20,558. Preventing Horses form Kicking, M. E. Medhurst, Cardiff.
20,559. Babies' Pacifier, Toys, &c., A. S. Cartwright, Birmingham.
20,560. Raising Nap on Textile Fabrics, A. D. McLaren, S. Irwin, and L. H. Marsden, Manchester.
20,561. Electric Arc Lamps, G. W. Lowcock, Manchester.
20,562. Rims for Cycles, B. and W. H. Barton, and W. S. London, Leicester.
20,563. Pneumatic Tires, T. Sloper, Devizes.
20,564. Clip for Securing Umbrellas, M. Egginton, Reading.
20,565. Automatic Two-speed Cycle Gear, J. Beesley, Coventry.
20,566. Nursery Chair, J. Davies, London.
20,567. Holders for Photographic Films, H. R. Cox, Cork.
20,568. Train Tablet Lock, J. E. Griffith and S. T. Dutton, Worcester.
20,569. Peeling and Washing Machines, E. Birch, Manchester.
20,570. Self-acting Coal Box, C. Quin, Ascot.
20,571. Dark Slide for Cameras, B. Wilkinson, Manchester.
20,572. Perfume Bottles, B. Hennig and M. Jahn, Manchester.
20,573. Pencil Cases, Perry and Co. and J. Clement, Birmingham.
20,574. Vulcanisation of Timber, W. E. Heys.—(*F. E. Grumbacher, Germany.*)
20,575. Fixing Shields for Gauge Glasses, H. Field, London.
20,576. Raising a Sunken Ship, G. W. Patterson, Reading.
20,577. Storing Postcards, The Stamp Distribution (Parent) Company and J. Frazer, London.
20,578. Fog Signal Machine, M. M. Buckley and W. Cash, Elland, Yorks.
20,579. Dress Support, W. H. and T. H. Finney, London.
20,580. Spinner for Fishing Tackle, P. D. Malloch, Glasgow.
20,581. Lids of Saucepans, &c., H. B. Banbury, London.
20,582. Lamps, E. Bosanko, London.
20,583. Construction of Ships' Rudders, J. Spear, London.
20,584. Roller Blinds, F. G. Gardiner, London.
20,585. Fastening Buttons to Boots, S. L. Pearce, London.
20,586. Pins of Brooches, J. B. Stewart, London.
20,587. Paraffin Lamps, D. G. Lewis and J. Davis, London.
20,588. School Desks and similar Furniture, G. A. Spink, London.
20,589. Doubling Spindles, R. Crabtree and J. Hargreaves, London.
20,590. Brackets for Mantelboards, H. and B. Bracewell and T. Whalley, London.
20,591. Buffers for Water-closets, J. Duckett and Son, Ld., and S. Middleton, London.
20,592. Preventing Halation in Photography, R. Roberts, London.
20,593. Matches, &c., G. Schinko.—(*A. Thimann, Austria.*)
20,594. Fixing Buffing Springs, T. D. and H. W. Swift, Liverpool.
20,595. Railway Signalling Device, W. Grimes, London.
20,596. Electric Accumulators, S. Hammacher, Liverpool.
20,597. Middlings Purifiers, W. N. Whitmore and G. Binyon, London.
20,598. Stamping or Marking Bale Bands, W. Hall, Liverpool.
20,599. Advertising, A. R. Upward, London.
20,600. Printing Photographs, J. W. Shaw and H. W. Chinnery, Walthamstow.
20,601. Scissors Sharpeners, J. T. Pedersén and A. B. Young, London.
20,602. Separating Postage Stamps, C. E. Smith, London.
20,603. Applying Brake Power to Cycles, J. Morton, London.
20,604. Knitting Machines, E. Mills, A. S. Rogers, and W. S. Thomson and Co., London.
20,605. Steam Generators, C. D. Jermyn, London.
20,606. Coupling-bar for Railway Cars, J. Spence, London.
20,607. Key, W. Prosser, London.
20,608. Bicycle Wheels, C. V. Craster, J. C. and G. L. Imeson, London.
20,609. Candles, W. B. Fitch, London.
20,610. Manufacture of Glass Bottles, W. B. Fitch, London.
20,611. Doll's Apparel, C. G. Mason, F. A. Foster, J. C. Elms, jun., and S. Sprague, London.
20,612. Window Catch for Carriages, A. E. Mallandain, London.
20,613. Electric Relays, &c., C. Langdon-Davies, London.
20,614. Electric Heating Wires, F. W. Schindler, London.
20,615. Reducing Aluminium, J. C. Fell.—(*F. A. Gooch and L. Waldo, United States.*)
20,616. Reducing Aluminium, J. C. Fell.—(*F. A. Gooch and L. Waldo, United States.*)
20,617. Cycle Saddles, J. Harrington and T. Middlemore, London.
20,618. Door and Window Check, L. Bonvoisin, London.
20,619. Grain, &c., Drying Apparatus, J. Sleeman, London.
20,620. Post, Letter, and Money Boxes, L. A. Parrock, Birmingham.
20,621. Railway Couplings, R. B. Eggar and D. Petrie, London.
20,622. Carbonate of Soda, P. Bateson and E. K. Muspratt, London.
20,623. Cycle Frames, C. F. Pichard, London.
20,624. Stretchers for Trousers and the like, J. A. Cheape, London.
20,625. Jointing Sewerage Pipes, F. H. Brook, London.
20,626. Label Fastener, J. B. Fisher and H. J. Hayes, Norwich.
20,627. Automatic or "Maxim" Guns, H. S. Maxim, London.
20,628. Studs for Cuffs and Shirts, A. Lehmann, London.
20,629. Trolley Carriers for Step Ladders, W. J. Sumner, London.
20,630. Devices for Copying Books, L. M. Bärwinkel, London.
20,631. Fire Escapes, E. I. Blount, London.
20,632. Crimped Paper Articles, H. J. Drane, C. Moritz, and P. Chant, London.

*29th October*, 1894.

20,633. Window Blinds, J. F. Waters, London.
20,634. Runners for Umbrellas, C. Wood and A. E. Busby, Birmingham.
20,635. Manufacture of Horseshoes, G. Welch, Sheffield.
20,636. Preservation of Steel, &c., A. Ryrie, Co. Durham.
20,637. Wind Motors, G. Moseley and W. Tapling, Kingston-on-Thames.
20,638. Lacing Boots and Shoes, T. Laycock, Wellingborough.
20,639. Handles for Trunks, F. W. Whitlock, Wolverhampton.
20,640. Tipplers for Wagons, S. Tate, Newcastle-on-Tyne.
20,641. Wrenches, A. A. Tattersall, Glasgow.
20,642. Pickers for Looms, T. F. Percival, Glasgow.
20,643. Cycle Frames and Forks, W. Andrews, Birmingham.
20,644. Two-reel Sawing Machines, D. Flanagan, Halifax.
20,645. Portable Barometer, J. Joly, Dublin.
20,646. Iron-band Cutter, C. A. Devenish, Birkenhead.
20,647. Life-saving Apparatus, A. Woodward, Cardiff.
20,648. Umbrella, W. H. O'Brien, Dublin.
20,649. Paper Winding Machinery, J. W. Hacking, Darwen.
20,650. Gypseous Walls, L. Küpper, Germany.
20,651. Measuring Areas, &c., H. S. Hele-Shaw, Liverpool.
20,652. Eye-glass Suspender, D. Roberts, Llanfairfechen.
20,653. Gas Engines, H. and A. E. Robinson, Manchester.
20,654. Bellows, E. Decesari, London.
20,655. Joints for Cornice Poles, W. Allman, Birmingham.
20,656. Separating Dust from Air, W. C. Morison, Birmingham.
20,657. Football Inflator Valve, P. J. Morris, Erdington.
20,658. Harness Buckles, W. Albery, London.
20,659. Two-wheel Cycle, J. P. Howe, London.
20,660. Lids for Pans, J. Turner and H. Seddon, Manchester.
20,661. Watering Carts, J. Stenfield and T. Becker, Cologne.
20,662. Ceilings, J. Schmitz and C. Bürker, Cologne.
20,663. Protectors for Water-gauges, J. Büllerbach, Cologne.
20,664. Protector for Cycle Tires, W. Rebentisch, Cologne.
20,665. Testing Tubes or Fittings, J. Davies, Wednesbury.
20,666. Umbrellas, E. Lewis and T. S. Nicholls, London.
20,667. Tents, H. Heaton, jun., and H. D. Hope, London.
20,668. Hanging Lamps, R. H. Best, London.
20,669. Pneumatic Horse-collar, J. H. Barnett, Leeds.
20,670. Mat-cleaner, H. Hughes and W. L. Pearson, Dublin.
20,671. Fastening Folding Shafts, &c., G. Lacy, London.
20,672. Game of Skill, J. B. Young, London.
20,673. Safety Purse, W. H. A. Sleigh, London.
20,674. Fastening Boots to Feet, J. Dunbar-Brunton, London.
20,675. Cycle Pedals, E. P. Gilman, London.
20,676. Gas Meters, F. Moore, London.
20,677. Water-closet Trap, R. F. Moore.—(*E. C. S. Moore, Bermuda.*)
20,678. Barometers, H. Wilson and F. G. Phillips, London.
20,679. An Improved Plough, G. W. Tiffen, London.
20,680. Cycle Saddles, C. Thomann, London.
20,681. Chimney Pots, J. W. Brown, London.
20,682. Boots and Shoes, H. Fogerty, Cheltenham.
20,683. Dusting Piano Keyboards, A. Seebold, London.
20,684. Cleansing Sand, F. A. Cowell and F. P. Candy, London.
20,685. Taps for Measuring Liquids, H. W. Turner, London.
20,686. Combustion Chambers of Furnaces, R. Marshall, London.
20,687. Pneumatic Tires, J. Iddon and J. E. Baxter, London.
20,688. Lubrication of Pulleys, W. H. Cranstone, London.
20,689. Stoves, E. E. F. Golterman, London.
20,690. Manufacturing Seamless Tubes, P. Hesse, London.
20,691. Machinery for Rolling Metal, P. Hesse, London.
20,692. Preservation of Liquid Food, P. Reichard, London.
20,693. Acoustic Device for Telephones, A. Maceland, London.
20,694. Urinals, F. A. Wells, London.
20,695. Water-closets, F. A. Wells, London.
20,696. Weaving Cotton Dusters, &c., D. Scott, London.
20,697. Duster, D. Scott, London.
20,698. Multiple Boring Machine, V. and G. Jetley, London.
20,699. Spray Bath, E. Tabor, G. Hinchcliffe, and W. A. Finch, Cambridge.
20,700. Knitting Machines, F. W. Golby.—(*L. Bosi, Italy.*)
20,701. Sanitary Towel Napkin, D. Scott, London.
20,702. Producing Letters, Words, &c., C. Chester, London.

20,703. Telephonic Switch and Indicator, G. L. Anders, London.
20,704. Cigar Lighters, G. W. La Baw, London.
20,705. Ancestral Record Book, F. W. Bailey, London.
20,706 Steel Stiffeners for Dresses, G. Rosenwald, London.
20,707. Hydraulic Accumulators, &c., G. Fletcher, London.
20,708. Expansion Joints and Couplings for Pipes, W. S. Dawson, London.
20,709. Grooving Cardboard, T. Sowersby and W. Allen, London.
20,710. Dog Kennels, W. T. C. Bruce and A. Still, Liverpool.
20,711. Safety Pins, H. A. Dale, London.
20,712. Press Copying Books, W. P. Thompson.—(*W. A Cooke, jun, United States.*)
20,713. Cycle Brakes, J. S. Foley, London.
20,714. Apparatus for Cleaning Grain, J. Higginbottom, Liverpool.
20,715. Making Cardboard Boxes, T. Sowersby and W. Allen, London.
20,716. Portable Electric Light Circuits, P. T. Letchford, London.
20,717. Brakes for Road Vehicles, G. S. Thompson, London.
20 718. Valves for Pneumatic Tires, G. H. Tansley, London.

*30th October*, 1894.

20,719. Treatment of Town Refuse, S. Willoughby, London.
20 720. Apparatus for Supporting Curtains, F. W. Perry, London.
20,721. Handle-bars for Bicycles, &c, E. Telling, London.
20,722. Anti-slipping Goloshes for Horses, T. Johnson, Dudley.
20,723. Miniature Hand Hearse, C. Oldfield, Macclesfield.
20,724. Caulking for Sewer Pipe Joints, T. Thorp, Whitefield.
20,725. Gun Carriages, J. G. Hartell, J. Watson, and E. A. Brandon, Bristol.
20,726. Link Belts, W. T. Rowden, Glasgow.
20.727. Miners' Safety Lamps, S. H., M, and W. Ellis, Wakefield.
20,728. Pedals and Cranks of Bicycles, T. Knowles, Manchester.
20,729. Wheels for Light Vehicles, F. Walker, London.
20,730. Cleaning Glass, T. Bevington, Bristol.
20 731. Carrying Liquid Substances, J. C. Wilson, Lancashire.
20,732. Bath, G. Chisholm, jun., Glasgow.
20,733. Making Woven Belting, J. Oswald, Manchester.
20,734. Excavators, S. Porter, Liverpool.
20,735. Bodies for Incandescence, O. Tiegs, Manchester.
20,736. Kilns for Firing Bricks, &c., J. S. Stein, Glasgow.
20,737. Carrier for Packages, E. C. Gripe, Manchester.
20,738. Dry Closets, R. C. Sayer, Bristol.
20,739. Stopping Currents of Air, W. C. Morison, Birmingham.
20,740. Door Locks and Latches, H. Wylde, Birmingham.
20,741. Hammer, T. W. Newey and J. H. Newey, Birmingham.
20,742. Manufacture of Staples, &c., C. March, Glasgow.
20,743. Locking Seats of Polo Carts, C. Glasgow, Glasgow.
20,744. Apparatus for Purifying Sewage, E. W. Ives, Derby.
20,745. A Book Cover, W. M. Sladdin, London.
20,746. Prepayment Gas Meter, F. Villiers-Stead, London.
20,747. Tents, J. J. Rinn, Liverpool.
20,748. Delivering Powdered Substances, F. Huldchinsky, Manchester.
20,749. "Flossa" Apparatus, O. E. Wollert, Manchester.
20 750. Pneumatic Arrangement for Beds, O. Y. Rhodes, Leeds.
20,751. Low-water Alarm for Boilers, R. Tonge, Pendleton.
20,752. Supplying Coal to Mechanical Stokers, J. Proctor, Manchester.
20,753. Mechanical Stokers, S., H., and L. Hall, Manchester.
20 754. Jacquard Machines, A. and H. I. Lawton, Manchester.
20,755. Tubes and Pipes, S. J. and H. E. Norton, Upton Manor, Essex.
20,756. Chucks, E. Sonnenthal and G. Sonnenthal, London.
20,757. Pneumatic Dome Tents, J. B. Small, Glasgow.
20,758. Pneumatic Collar and Saddle Pads, W. Gillman, Dublin.
20,759. Pipe Plug and Nicotine Absorber, A. G. Thomas, Leeds.
20,760. Elastic Wheels for Cycles, &c., G. Ross, London.
20,761. Vessels for Honey, J. S. Green, F. R. Syms, and W. Adams, London.
20,762. Fastening Castors to Furniture, N. Harker, London.
20,763. Combing Vegetable Fibres, T. Burrows and D. E. Radclyffe, London.
20,764. Stringed Instruments, D. Mayer and W. Robinson, London.
20,765. Shirts, F. C. Parker, London.
20,766. Braces, &c., R. E. Daish and M. M. Dessau, London.
20 767. Contrivance for Steering Ships, R. M. Phillips, London.
20,768. Hand Camera, A. J. Jones and S. J. Levi, London.
20,769. Automatic Valve for Starting Compound Engines, W. E. Worrall, London,
20,770. Screw Propellers, W. H. Jay, London.
20,771. Naval Handkerchief, C. Fulton, London.
20,772. Regulating Speed of Engines, J. H. Greenwood, London.
20,773. Packing Hydraulic Rams, &c., D. Walton, London.
20,774. Hinges, E. Harnett, London.
20,775. Mechanical Toys, W. Britain, jun., London.
20,776. Microscopes and other Instruments, H. G. Sedgwick, London.
20,777. Water-closets, F. F. W. L. Müller, London.
20.778. Pneumatic Tire Horseshoe, G. T. Price and E. D. Brewer, London.
20,779. Projectiles, W. Whitley and J. Parker, Keighley.
20,780. Towel Racks, R. Haddan.—(*C. E. Cochrane, United States.*)
20.781. Preparing a Homogeneous Mixing Product, O. Fahnehjelm, London.
20,782. Roofing Tiles, G. Schulze, London.
20,783. Telephone Transformer, J. W. Ray, North Shields.
20,784 Electric Incandescent Lamps, H. J. Thiroux, London.
20,785. Wire Chains, F. W. Smith, jun., London.
20,786. Machines for Making Matches, E. B. Beeches and J. P. Wright, London.
20,787. Shirts and Cuffs, R. G. Knowles and N. P. Cook, London.
20,788. Making Type-printing Bars, J. C. Fowler, London.
20,789. Scouring and Cleaning Machine, G. Carlson, London.
20,790 Compounds for Filtering Liquids, C. D. Abel. —(*A. Schlumberger, France.*)
20,791. Pumps, H. E. Newton.—(*C. C. Worthington, United States.*)
20,792. Magazine Fire-arms, H. F. Woodgate, London.
20,793. Check Punches, C. A. Allison.—(*W. J. Jenner, United States.*)
20,794. Safety Slop-pail with Removable Strainer, K. B. Sharman, London.
20,795. Rotary Swathing Machine, T. M. Jarmain, London.
20,796. Manufacturing Beer, P. Kropf and A. Gruell, London.
20,797. Seamless Shoe, H. H. Lake.—(*St. Petersburg Boot and Shoe Manufacturing Company, Russia.*)
20,798. Railway Signalling Systems, W. P. Hall, London.
20,799. Tobacco Pipes, E. Ropp, London.
20,800. Cigar-bunching Machines, H. H. Lake.—(*H. A. Streeter and J. P. Bacon, United States.*)
20,801 Generation of Steam, J. E. T. Woods and J. B. Hamond, London.
20,802. Elevator Safety Attachments, C. B. Labatt, London.
20.803. Construction of Lime Kilns, J. H. Janssen, London.
20,804. Saucepans and Boilers, W. A. L. Bailey, London.
20,805. Preventing Kettles from Boiling Over, A. Shulver, J. Self, and G. Constance, London.
20,806. Beer and other Traps, H. G. Chamberlain, London.
20,807. Telegraph Transmitters, H. A. Taylor, London.
20,808. Steam Engines, M. N. Forney, London.
20,809. Forming Screw Threads on Rods, S. P. Lehmann, London.
20,810. Locket Cases for Portraits, &c., H. Penn, London.
20,811. Centering, J. J. Nobbs, London.
20 812. Preventing Boats Capsizing, C. A. J. Bien, London.
20,813. Sewing Machines, J. Chappell and T. R. Rossiter, London.
20 814. Ores, C. F. Claus, C. Goepner, and C. Wichmann, London.
20 815. Metallic Alloy, E. A. L. Langlois and P. F. de Susini, London.
20,816. Portable Sheds, D. Young.—(*La Compagnie des Constructions Démontables and Hygiéniques, France.*)
20,817. Chalking Billiard Cues, R. Naumann and C. Kunze, London.

*31st October*, 1894.

20,818. Cycle Saddles, T. Staines, J. Leadbeater, and A. Preston, Leeds.
20,819. Clock Timing Stand, G. E. Cornioley and A. Haiman, London.
20,820. Stands for Bottles or Jars, G. Burnett, Workington.
20 821. Douche, R. H. Rains, London.
20,822. Postal Cards, A. H. Hallen, London.
20,823. Pants, A. H. Hallen, London.
20,824. Opening and Closing Gates, R. E. D. Rudman and H. E. Williams, Chippenham.
20 825. Roller Brake for Cycles, H. Le Jeune, jun., London.
20,826. Bath Valves, G. Gregory, London.
20,827. Telephone Switchboard Jack, J. Taylor, Warrington.
20,828. Securing Mattresses, &c., to Bedsteads, F. Hoskins, Birmingham.
20,829. Buttons, A. Appleby, Birmingham.
20,830. Toy, W. J. Hawke, St. Austell.
20,831. Teaching Apparatus for Schools, G. Wood, Leeds.
20,832. Fibre Spinning Machinery, A. Hitchon, Accrington.
20,833. Brakes for Railway Wagons, H. T. Purdon, Dublin.
20,834. Testing Cycles, J. J. H. Sturmey and G. D. Leechman, Coventry.
20,835. Knitting Machine Needles, G. F. Sturgess, Leicester.
20,836. Replacing Derailed Wagons, J. Brook, Sheffield.
20,837. Smoking Pipes, H. J. Marsden and J. W. Bagshaw, Sheffield.
20,838. Inflating Elastic Tubes, W. and J. Ellis and T. Spurr. Hull.
20,839. A Mechanical Toy, W. S. Adams, Gateshead.
20,840. Elastic Tires, W. H. Bird and C. Erade, Leicester.
20,841. Steam Engine Pistons, W. Owen and T. Fryer, Staffordshire.
20,842. Electric Railway Vehicles, T. Machin, Birmingham.
20 843. Electric Railway Vehicles, T. Machin, Birmingham.
20,844. Attaching Labels to Railway Wagons, R. Mustard, Birmingham.
20,845. Combination of Locks, H. K. Morley, Manchester.
20,846. Securing the Covers of Pneumatic Tires, H. Weatherill, Manchester.
20,847. Memorandum Forms, W. G. Leatherbarrow, Lancashire.
20,848. Portland Cement, E. Wilder and H. Holt, Kent.
20,849. Making Portmanteaus, R. M. T. Murdoch, London.
20,850. Appliances for Drawing, A. C. Snell, Cornwall.
20,851 Preventing the Loss of Parasols, &c., J. S. Martin, London.
20,852. Disinfectant Compound, E. Burton, London.
20,853. Advertising Station, F. Villiers - Stead, London.
20,854. Reducing Cycle Vibration, D. B. Brazier and W. F. Eaton, London.
20,855. Lavatory Basins, M. J. Adams, York.
20,856. Speed Gear for Cycles, J. C. Webster, London.
20,857. Locking Nuts, A. W. Daw and Z. W. Daw, London.
20,858. Cycle Locks, S. C. Hone, London.
20,859. Candlesticks or Holders, F. W. Field, London.
20,860. Vehicles, W. G. MacIvy and the Princess Company, Ld., London.
20,861. Railway Signalling Apparatus, W. B. Quelch, London.
20,862. Closing Bottles, Jars, and the like, T. Pink, London.
20,863. Sifting Apparatus, A. Rohrbach, M. Meyer and W. Bindewald, London.
20,864. Printing from Photographs, A. P. Negley, London.
20 865. Wire Chain, F. W. Smith, London.
20,866. Chimneys of Gas Stoves and Fires, J. Atkins, London.
20,867. Wheel Tires, S. C. Peuchen and P. Clarke, London.
20,868. Postal Envelopes, W. Orchard and J. Wright, Liverpool.
20,869. Fire-proof Doors, &c., G. F. Bowman, London.
20,870. Footballs, S. Kramrisch, Liverpool.
20,871. Car Starters, H. M. Crisp and H. F. Wilson, London.
20,872. Method for Extraction of Gold, P. De Wilde, London.
20,873. Driving Gear for Cycles, J. and J. Saxby, London.
20,874. Mixing Liquids, A. Bloch, London.
20,875. Table for Parlour Games, A. C. D. Seifert, London.
20,876. Clasp for Belts, F. L. Brunet and J. Lévy, London.
20,877. Softening Leather, C. A. Hardy and R. Dodgson, London.
20,878. Babies' Feeding Bottles, L. F. Beesley, London.
20,879. Fastenings for Boots, &c., W. A. Saunders, London.
20,880. Boiler Tube Joints, C. McKenna, Newcastle-on-Tyne.
20,881. Sewer Ventilating Apparatus, S. Holman, London.
20,882. Tobacco Pipes, F. Laycock, London.
20,883. Apparatus for Labelling Bottles, E. Perry, London.
20,884. Device for the Use of Smokers, J. Hume, jun, London.
20,885. Trouser Suspenders, W. Bennett, jun., London.
20,886. Telegraphic Relays, A. D. Macdonald, London.
20,887. Blackboards, E. Edwards.—(*W. Antony, Germany.*)
20,888. Tubular Boilers, A. van Overbeeke, London.
20 889 Pneumatic Tires, G. H. E. and T. Cooke, London.
20,890. Delivering Goods, F. Origgi and G. Caimi, London.
20,891. Side Arm Fittings, H. Garner and T. Perry and Son, London.

*1st November*, 1894.

20,892. Governors for Steam Motors, H. F. C. Whitehead. Stockport.
20,893. Oval Hinged Door, R. Sheard, Wakefield.
20,894. Apparatus for Ringing Cycle Bells, F. Clelland and J. Jessop, Manchester.
20,895. Self-registering Frame, T. J. Jenkins, London.
20,896. Locking Angle Iron Fencing, I. Price, Wolverhampton.
20,897. Construction of Tip Wagons, J. and C. Smith, Barnard Castle.
20,898. Cycle Brakes, O. S. Wraith and J. W. Dean, London.
20,899. Corset Busks, J. J, W. and J. E. Clarke, and F. R. Baker, Birmingham.
20,300. Teaching Apparatus, G. Wood, Leeds.
20,901. Steam Motors, W. M. Walters, Liverpool.
20,902. Spring Tires for Cycles, J. Barlow, Nottingham.
20,903. Horseshoes, H. Pickles, Bradford.
20,904. Metallic Mounts, T. Morton, Birmingham.
20,905. Cycle Hubs, J. G. F. Temple, Birmingham.
20,906. Portiere Rods, J. F. Hall-Edwards, London.
20,907. Tents, H. Heaton, jun., London.

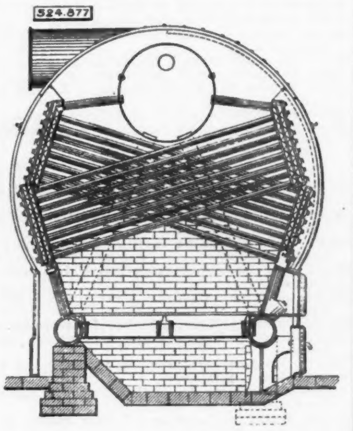
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**524,877.** Sectional Steam Boiler, *A. Worthington, Brooklyn, N.Y.—Filed June 2nd*, 1893.

*Claim*—In a sectional steam boiler, the combination, with a plurality of series of oppositely inclined water tubes, a steam and water drum, a plurality of water drums extended longitudinally of the boiler, and tubes for independently connecting the steam and water drum with the water drums and for connecting such water drums, of a water arch for connecting one of the series of water tubes to one of the water drums, whereby to form a door or stokehole with the water arch extended above and the water drum extended below the same, tubes and headers for connecting the other series of water tubes with the other series of water drums and for connecting both series of water tubes with the steam and water drum, and a fire-box or furnace located below the water tubes, substantially as described.

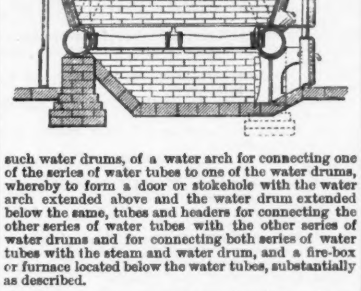
524.877



**524,902.** Fire-box for Steam Boilers of Locomotive Type, *W. Malam, Fairfield, England.—Filed October 30th*, 1893.

*Claim*—(1) A corrugated fire-box of a locomotive type of boiler having vertical corrugations formed in the body of the side sheets, the said corrugations being wedge shaped, that is to say, of the full depth at or near the top and gradually diminishing toward the line of grate bars, so as to obtain the increased heating surface without diminishing the area of the fire-bars, substantially as hereinbefore described. (2) The combination of a corrugated fire-box having vertical wedge-shaped corrugations formed in the body of the side sheets, with a water space extending beneath the bottom of the said fire-box, substantially as hereinbefore described.

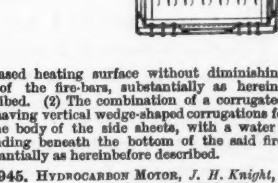
524.902



**524,945.** Hydrocarbon Motor, *J. H. Knight, Farnham, England.—Filed November 16th*, 1893.

*Claim.*—(1) In a hydrocarbon motor, a vaporiser having two chambers, one of which constitutes a vaporising chamber that is normally disconnected from, but is adapted to be placed at intervals in communication with the combustion end of said cylinder, and the other of which is in free and constant communication with the combustion end of said cylinder, substantially as herein described for the purpose specified. (2) In a hydrocarbon motor, the combination with the motor cylinder, of a vaporiser comprising the casing 1 provided with an inlet 4 and outlet 5, controlled by a valve 6, metal plates arranged within the vaporising chamber between the lower and front sides of said casing and adapted to transmit heat from one to the other, and a metal tube or chamber 10 closed at its rear end and in open connection at its other end with the motor cylinder and extending into said vaporising chamber substantially as herein described.

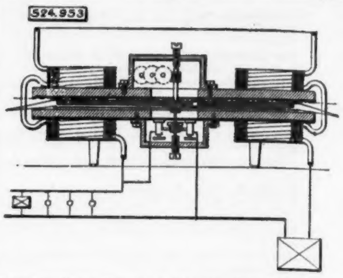
524.945



**524,953.** Electric Meter, *C. D. Raab, Kaiserslautern, Germany.—Filed January, 18th*, 1894.

*Claim.*—An electric motor meter comprising. the revolving armature having the coils in a shunt, the damping discs adjacent to the armature, the stationary coils and conductors and the mica discs interposed between the armature and the damping discs, whereby the air damping will be reduced, substantially as described.

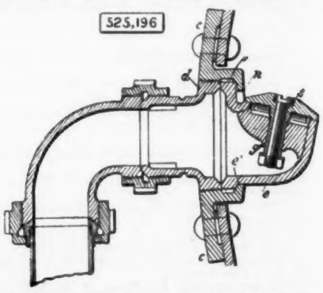
524.953



**525,196.** Safety Check Valve, *J. M. Foster, Elizabeth, N. J.—Filed September 30th*, 1893.

*Claim*—(1) A removable inside boiler check valve, and in combination therewith a suitable flanged supporting piece and a retaining ring adapted to be screwed therein as described and set forth. (2) The flange piece *c*, provided with the auxiliary seat *c'*, and clip *n*, in combination with a valve, the removable valve body, as *e*, provided with the flange portion *v*, and corresponding clips *n'*, *n'*, and suitable retaining ring as *d*, as and for the purpose specified. (3) A check valve provided with a sleeve as *g*, in combination with the bolt *s*, and slotted nut *h*, and projections *g'* for engaging the slots in the nut arranged and constructed substantially as herein specified. (4) The combination of the auxiliary seated flange piece *c*, valve body as *e*, sleeve valve piece "B," provided with the wings *i*, *i*, a valve seat in which the said valve reciprocates, bolt *s*, and nut *h*, all constructed and arranged and held in position by the retaining ring piece *d*, as illustrated and described.

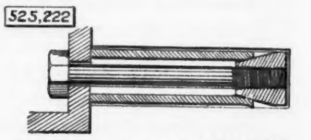
525,196



**525,222.** Expansible Bolt, *W. M. Levering, Philadelphia, Pa.—Filed April 16th*, 1894.

*Claim.*—(1) In an expansible bolt. a sleeve having a longitudinal slot extending a portion of the length thereof, and a neck at the end of said slot forming an integral portion of the wall of said sleeve, a bolt entering said sleeve, and a conical nut on the threaded end of said bolt having a spline on its side interlocking with the end of the sleeve, the body of the nut contacting with the inner wall of the sleeve adjacent to said spline, the parts being combined substantially as described. (2) An expansible bolt consisting of a sleeve having a division extending the entire length thereof, and a slot extending a portion of the length thereof, a connecting neck at the end of the latter division forming an integral part of the wall of the sleeve, a bolt with a threaded end, and a conical nut with a spline on its side, guided in said division and slot, said parts being combined substantially as described.

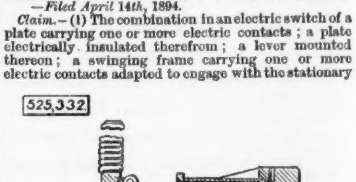
525,222



**525,332.** Electric Switch, *G. F. Card, Covington, Ky.—Filed April 14th*, 1894.

*Claim.*—(1) The combination in an electric switch of a plate carrying one or more electric contacts; a plate electrically insulated therefrom; a lever mounted thereon; a swinging frame carrying one or more electric contacts adapted to engage with the stationary contacts; an air cylinder upon the swinging frame having an aperture adjacent to the contact point; a piston adapted to reciprocate in the cylinder; a spring adapted to press the piston in the direction of the aperture, and a connection between the piston-rod and the lever whereby the piston-rod may be actuated, substantially as and for the purpose set forth.

525,332



Throat Irritation and Cough.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. In contact with the glands at the moment they are excited by the act of sucking, the Glycerine in these agreeable confections becomes actively healing. Sold only in boxes, 7½d.; tins, 1s. 1½d, labelled, "James Epps and Co., Homœopathic Chemists, London."

## THE PROPOSED CARDIFF HARBOUR TRUST AND SOUTH WALES DOCK EXTENSION.

In the annual story of progressive action among the ports on the Welsh Coast of the Bristol Channel, a first place needs to be given to the movement for the constitution of a Harbour Trust for Cardiff, which until this week had seemed to have reached success. Thirty years ago far-sighted observers of the signs of the times and the possibilities of the district, urged it as a question of expediency and a provision for the future. During the past ten years the project has forced itself more and more upon the attention of a shrewder public as a matter of necessity. The competition between neighbouring ports on the Welsh littoral, the increasing rivalry of aggressive ports elsewhere, and the evidence accumulating on every hand that if Cardiff is to continue to advance it must add an import trade to the coal export of its docks, have within the last two or three years brought the issue to a critical point. There is no reproach to the present dockowners that they have not kept pace with the ever-growing demands of the coal-shippers for larger accommodation and quicker dispatch. The claim and the lament is rather that the dock companies have devoted their enterprise and energies exclusively to exports of coal and rails, which practically monopolise the dock accommodation, and have not offered due encouragement to the import trade which the geographical position of the port and the great population of its "hinterland" might be expected to invite. The "dockising" of the capacious harbour is the demand of to-day, and for two reasons. It should be the means of reclaiming large tracts of the foreshore which would be available as the sites of warehouses, oil and seed crushing works, manufactories, and—as the more sanguine anticipate—even cotton mills. It would also afford space for discharging and warehousing inward cargo at spots remote from the inevitable dust, dirt, and other inconveniences attaching to the constant tipping of coal. All the interests in the port—the dock proprietaries, the shippers and merchants, and the local railway companies—are agreed in the abstract that such a scheme is desirable and not impossible. But in and between those interests there are keen competitions and jealousies, and in the absence of an incentive to common action nothing is done. The harmonising element, it was believed, would be found in the creation of a representative body, on the initiative of the Cardiff Corporation, which should incorporate all the docks, and railway adjuncts to the docks, together with the necessary and adjoining lands, under the style and with the powers of a statutory Harbour Trust. It looks a vast scheme; it involves the acquisition of properties estimated to be worth seven odd millions sterling. It is a greater scheme than the Tyne or Glasgow undertook in the infancy of their Harbour Trusts, inasmuch as they began in the beginnings of their prosperity, while Cardiff has to take over some of the largest and best-equipped dock properties in the kingdom. The idea, however, was exhaustively examined from all points of view by a committee of the municipality for twelve months past, and the final report was a strong recommendation to the Corporation to carry out the plan by (1) taking steps to acquire the various estates on a 4 per cent. basis and twenty-five years' purchase, and (2) pledging the Borough rates as security, and borrowing at 3 per cent.; the difference between the 4 per cent. ensured to the vendors and the 3 per cent. to be paid for the loan representing a distinct gain to the Corporate Trust on the financial side of the transaction alone.

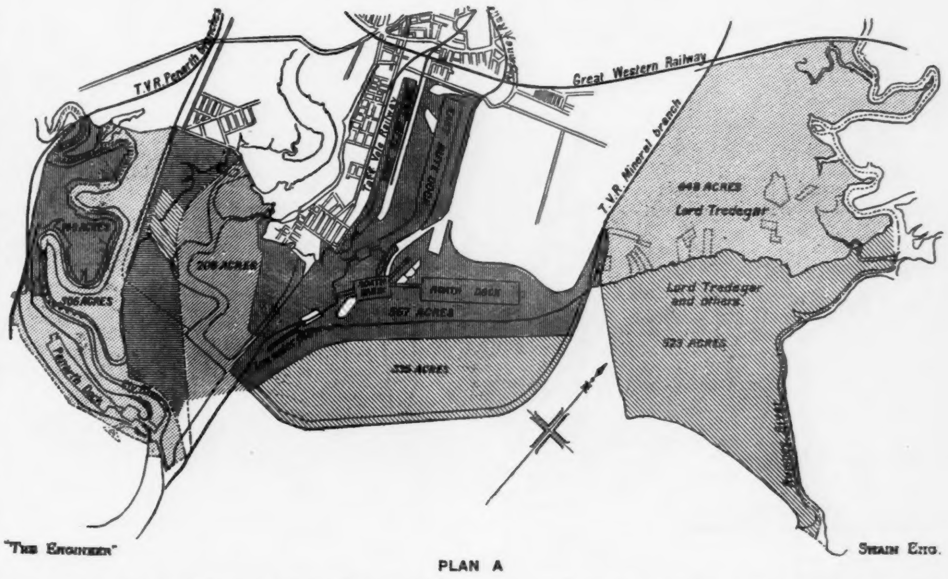
The Cardiff County Council has had before it the plans, and an elaborate report which has been framed by the Corporation Trust Committee, after careful inquiry into the constitution of other Harbour Trusts, and a series of interviews with Sir W. T. Lewis, of the Bute Docks, the representatives of Penarth and Barry Docks, Lord Tredegar's solicitors in reference to portions of the foreshore, and the directors of the Taff Vale and Rhymney Railways. The plan A we reproduce excludes the Barry Dock estate, and deals solely with the properties comprised in Cardiff Harbour between Penarth Head on the west and the Rumney river on the east.

Lord Tredegar's land, which it was proposed to acquire for building purposes, lies between the Taff Vale mineral branch and the river Rumney, its northern boundary being the Great Western Railway. It contains 1171 acres, including foreshore, and a large portion has already been surveyed in connection with a dormant scheme for constructing docks at the mouth of the Rumney. The Bute Docks property is sufficiently described on the plan, and covers an area of 892 acres. To the westward extends the land of Lord Windsor, and the estate of the Penarth Dock and Harbour Company, held on a 999 years' lease by the Taff Vale Railway. The whole of the dock works, lands, and foreshore, to be taken over by the Harbour Trust, is 2900 acres, and it is pointed out in the report that the amalgamation of all the interests therein comprised would probably make it necessary to incorporate the township of Penarth in the Borough of Cardiff. The report continues:—

> Your Committee would point out that a portion of the land proposed to be acquired would to a certain extent remain unproductive in the immediate future; still they consider it most advisable to secure it, for in the natural course of things, with the extension of the docks and trade, this land will increase immensely in value, and they could not recommend the Council to secure the dock property alone without acquiring even a surplus of land for the building of works, warehouses, and manufactories, so as to be in a position to provide cheap land to traders and others willing to take advantage of the development of the trade of the port, and the facilities afforded by its geographical position. Most ports are suffering from the want of land in the vicinity of their docks. Bristol and Swansea are much handicapped in this direction at the present time. The Mersey Docks and Harbour Board, of Liverpool, are now buying land for enlarging their docks at sums very much in excess of those at which such land could have been secured not very long ago. Your Committee could mention many similar cases, and are particularly anxious to avoid the oversights of those other Trusts who have been good enough to draw the attention of your Committtee to the lesson taught by experience as to the unwisdom of not securing sufficient land at the outset. Cheap land your Committee consider as essential as any other part of the undertaking, for Cardiff is sadly behind many other ports in works and manufactories, and for the development of an import trade these businesses are necessary. Once you induce merchants and manufacturers to build works and warehouses you have practically linked them to the port, for even with fluctuations of trade they cannot move their buildings from one port to another.

The Committee concluded by expressing its firm conviction that its inquiries and its negotiations with the dockowners and others had so far progressed as to call for a further and more practical step in advance. On its recommendation the Council resolved by large majorities to pledge the Borough rates as security for a £3 per cent. loan, if the project showed a £4 per cent. net profit on the average of the last three years. To test this question, it was further decided that Mr. R. W. Hedley, who has special knowledge of the dock accounts involved, should be appointed valuer for the Corporation, and Mr. R. W. Perks, M.P., whose financial connection with the Barry undertaking is historical, was named financial adviser, on honorary terms, at Mr. Perks' own request, that gentleman intimating that his remuneration would come from the capitalists who found the seven millions, more or less, required.

The next step was to obtain the consent of the dockowners and others to the proposed examination of their books for the three preceding years. Lord Tredegar had from the first expressed his willingness to assist the Trust Committee in every way. The Marquis of Bute, and the Bute Dock Company, through Sir William Thomas Lewis, raised no difficulty; and for some time past Mr. Hedley has been pursuing his investigations into the accounts of the various Bute estates. It is not improbable that the Chancellor of the Exchequer may have indirectly facilitated the progress of the Harbour Trust movement in regard to these particular properties. The Marquis of Bute and Lord Tredegar are possibly of opinion that it is more advantageous to transfer their lands and works on the terms proposed, than to leave them subject to the enhanced death duties which would fall upon their successors.



"The Engineer" Swain Eng.

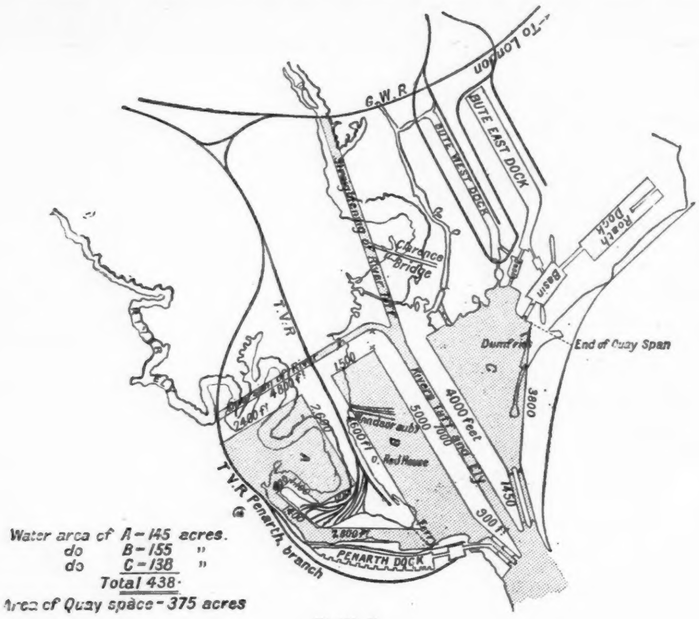
PLAN A

So far matters had progressed up to November 10th, when a meeting of the Harbour Trust Committee was held, to receive an important report from Mr. Hedley and a financial statement from Mr. Perks, M.P. It appeared at once from these documents that the seven odd millions set down as the capital required for the acquisition of the Barry, Penarth, and Bute Dock properties was far too modest an estimate. The cost of buying out the Bute Docks Company, together with Lord Bute's freeholds and reversions, is alone stated in Mr. Hedley's valuation at £4,701,653. But that is not all. Mr. Hedley goes on to say, "In addition to the capital required for the purchase of the proposed undertaking, the Corporation will have to provide sufficient capital for the current working expenses of the docks, the purchase of stores, capital for the construction of the new dock and equipment, and also the cost of the Bute Docks Act, 1894." This further sum is estimated to be upwards of £1,000,000, the new dock works involving an expenditure of £650,000, irrespective of equipment. The total charge, therefore, solely on the Bute Docks account, would reach at least six millions sterling. The Corporation Committee resisted stoutly the proposal that the Harbour Trust should carry out the new dock plan. It argued that its own plan was to construct a floating harbour, which would supersede the new dock, and offer greater advantages to the trade of the port. Sir W. T. Lewis, however, was inexorable on this point. The completion of the dock, he maintained, was an indispensable condition, as the demands of the trade required it, and it would be impossible to permit the delay which would be involved in the execution of the larger scheme of dockisation. To quote the text of Sir William Lewis's remarks on this head, "It is of the utmost importance, in order to prevent the diversion of traffic to rival docks, that the increasing demand for special accommodation for the larger class of vessels, and additional means of entrance and exit, with a larger lock and deeper sills, should be provided in connection with the Roath Dock and Roath Basin, with the least possible delay," and he further pointed out that in his opinion, based upon his forty years' experience at the Bute Docks, "the accommodation required to maintain the position of the port could not be otherwise provided so economically, while, either as regards direct communication with the various railway or the convenience of freighters sending traffic to the Bute Docks, no better site could be selected." But even upon terms so much higher than had been anticipated, Mr. R. W. Perks, M.P., advised the Corporation to proceed with the Harbour Trust. Taking the initial sum of £4,701,653 for the purchase of the Bute Docks properties, and excluding the new dock, he remarked that the figures show an actual and estimated annual revenue of 3½ per cent., and he believed that the necessary capital could be borrowed as Corporation Harbour Stock at 3 per cent., which would leave a margin of upwards of £35,000 a year between the revenues estimated and the interest on the debt. "Should Parliament," he added, "impose an annual sinking fund, even for sixty years, it will not involve, should Mr. Hedley's estimate of revenue be realised, any charge upon the rates of the town. The proposed purchase is one which, in my judgment, the Corporation may, as prudent business men, adopt, and which cannot fail under efficient control to conduce to the commercial and industrial progress of the port and town of Cardiff."

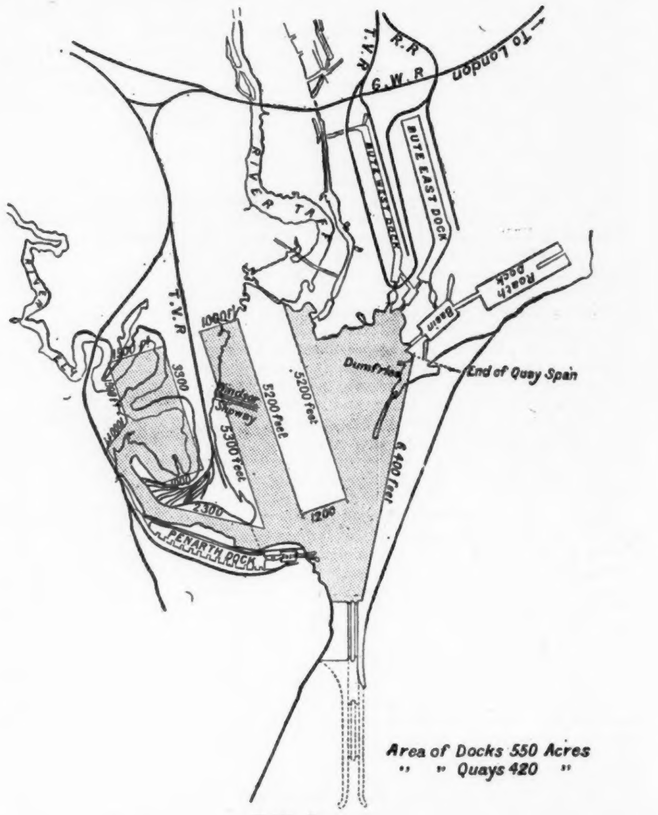
The Trust Committee had no plenary power, and in face of the unexpectedly large dimensions the purchase price had assumed, it was resolved to call an early meeting of the whole council to consider Mr. Hedley's report. Most unfortunately the "minute" sent to Sir W. T. Lewis, contrary to the view subsequently explained, stated that the committee "would proceed to negotiate with the other interests, with a view of obtaining from them the terms on which they are prepared to transfer their various properties." The special meeting of the Corporation was held on Tuesday last. In the meantime Sir W. T. Lewis had written and published a letter which fell on the borough like a "bolt from the blue." He wrote that "as the negotiations have proceeded on the distinct condition that the matter should be disposed of one way or another by the middle of this month," the transaction must be considered at an end, and neither of the parties he represented would be thenceforth bound by the terms he had discussed with Messrs. Perks and Hedley and the Trust Committee. There seems to have been some inexplicable and egregious blundering over the date Sir William Lewis appointed for a definite agreement, several members asserting that they were not told of it until Saturday, and others saying it had been an understanding all along. As to the Corporation in its collective capacity, it found itself in an *impasse*. In view of Sir William's letter, the question arose, What is to be done? Mr. Morel, a member of the Trust Committee, aware that there was a serious misunderstanding, and possibly a concealment of facts, moved that Sir William Lewis should be desired to withdraw his letter, and permit negotiations to continue. Mr. W. J. Trounce, ex-mayor, seconded the motion in the belief that it had been shown that the revenues of the dock properties—if purchased—would comply with the conditions laid down. A member, who suggested that the Corporation "should sing the doxology and go home," vehemently opposed this overture for renewed negotiations. After a wrangling and incriminatory discussion, the meeting resolved by 23 votes to 13 to abide by the terms of Sir William Lewis's letter. That ends the Harbour Trust scheme so far as this Corporation is concerned; for it is not to be expected that the Marquis of Bute or Sir William Lewis would reopen negotiations with a body of such instability of mind as the Cardiff Council seems to be.

Something more may possibly be heard at an early day of a trust or dock and railway combination scheme relating to the properties we have described, but in that event it would have its origin in a wealthy syndicate working for financial results, and not in a public corporation which is unable to hold the same views two months together.

According to the Harbour Trust plan there would have remained to be considered the negotiations with the Barry Railway and the Taff Vale Railway for the transfer of Barry and Penarth Docks. There can be no doubt that the inclusion of Barry presents more difficulties than any other part of the project. The Barry directors say that they would "be prepared to give due consideration to a scheme embracing every interest, and calculated to put an end to unnecessary rivalry and expensive Parliamentary contests, and to secure to the public the best facilities on the most economical terms. But until they are supplied with full details of the plans of the Corporation, they cannot see their way to definitively discuss the subject, or accede to the application for an inspection of their books." Some facts and considerations, however, stand out in relief, and they point to the conclusion that Barry must have been left out of the scheme. It is improbable that a company which earns 10 per cent.—a considerable proportion being derived from its dock receipts—and which is even now building a new dock of large capacity—would part with a portion of its property on a 4 per cent. basis. It would be a task of infinite complexity to sever the dock, dock railways, and adjacent lands and foreshores from the still expanding railway part of the Barry undertaking. It is held also in another quarter that it would be manifestly unfair to Cardiff that its municipal credit should be pledged for the purchase of property in a new town twelve miles away—a property which was dependent upon an independent railway company, and in a town over whose good or bad government, sanitary or insanitary condition, its indebtedness and its high or low rates, the Cardiff municipality would have no control whatever. The difficulty in the case of Penarth was more distinctly one of terms. The Taff Vale directors informed the Council that they are only lessees, though practically perpetual lessees, of the Penarth Dock and Harbour, and have no power to dispose of the property without the consent of the original shareholders. They are, moreover, under a specific obligation to pay these original shareholders 5¼ per cent. upon the capital expended in the construction of the dock and railway. They have spent themselves over £200,000 in additions to the dock property, on which they are paying dividends out of their general revenues at an equal, if not a higher rate than the Corporation proposes. They cannot therefore entertain the present offer; but they add, "They are perfectly willing, so far as their interests are concerned, to favourably consider any scheme for the formation of a Harbour Trust that would be for the advantage of the port and all concerned."



PLAN B



PLAN C

The Trust Committee declined to consider this reply as a *non possumus*. In the course of discussion it was pointed out that the Penarth Dock was old-fashioned, with an obsolete equipment, and so placed in a corner between the cliff and the Ely river that expansion was impossible, while there was no spare land to meet the demand for warehouse accommodation, &c. Doubt was expressed whether, since the opening of the Barry Dock, the Taff Vale had earned so much as 4 per cent. per annum on the Penarth Dock account. The Mayor further remarked that the area of the Penarth Dock holding was only 306 acres, while in Cardiff there were 2411 acres in the combined Bute and Tredegar Estates; while, with reference to the dockising of the harbour—the ultimate object of the Trust—"engineering experts would tell them that it was as easy to float the harbour from the north side of the river Ely to the pier of the new Bute Dock, as to carry the sea wall—as originally proposed—across the harbour to Penarth Head."

That may be; but the importance from an engineering point of view of including Penarth in the Trust estate is shown in the plans here annexed. With Penarth Dock and harbour excluded from the Trust, not only must a free outlet be left for the channel of the Ely, and the Dock traffic, but the proposed diversion of the Ely, by which a large tract of mud flats would be reclaimed, must be abandoned. Plan B illustrates the diversion of the Ely into the straightened Taff, and the greater water area and quay spaces, together with sites for warehouses and manufactories, that would thereby be afforded. The alternative plan, C, exhibits a larger area of quay space, and the piers or breakwaters which would form and guard the entrance channel. On both maps the point marked "End of quay space" indicates the site of the Sea-lock leading to the new dock to be constructed on the foreshore, south-west of the existing Roath Dock. A good deal would have depended upon the action Lord Windsor took up as the owner of part of the mud-flats west of the river Taff. He responded to the overtures of the Trust Committee in terms as cordial and encouraging as they could have desired. He had not been approached for a final settlement, and he would have an important voice in determining, irrespective of the Penarth Dock, how much of the harbour space may be enclosed and dockised.

The Bute Docks Company meanwhile, as will have been seen, is insisting on the need of proceeding with its new dock scheme, for which Parliamentary powers were obtained in the past session. Whatever becomes of the Harbour Trust project, the owners of the Bute Docks are under statutory obligations to complete their works within a term of years. They will go on with their undertaking irrespective of the Harbour Trust, for the reasons that (1) they are supplying a demand for increased shipping facilities, which increased demand should redound to their own profit; and (2) that all the works they lay down on their private account will become a more and more important asset, now or at some future time, among the properties the Trust Commissioners of the harbour seek to secure.

By the new Bill it was proposed to reclaim the mud flats —indicated as 335 acres—by building two sea walls, one 3050ft. in an easterly direction from the south-east corner of the Low-water Pier, now converted into an embankment; 3025ft. southerly from the south-west corner of the Roath Dock, and extending thence southerly and south-westerly to a point on the foreshore 2400ft. south-easterly from the same corner of the Low-water Pier, whence it will turn north-westerly, and terminate on the mud banks about 910ft from the piers. The other sea wall runs south-easterly for 800ft. from a point 120ft. to the eastward of the same pier, and thence 800ft. north-easterly and easterly to the fore-shore. Within the area thus enclosed—all practically land which will have been reclaimed—the new dock and entrance lock will be constructed. The dock itself is to be 2600ft. long by 650ft. wide, with an average depth of 30ft., or more than sufficient for the largest ship afloat. It will have a larger water area than the Roath Dock—*i e.*, thirty-five acres—and 6ft. 6in. more water on the sills, owing to the entrance lock being carried out to low-water spring tides; while another lock will give it communication with the Roath Dock, so that the two will combine a larger water space than any other dock in existence approached by a deep-water channel. The Sea Lock, or entrance, will be 700ft. long and 120ft. wide. There will be about 7000ft. of quayage space, and while the north-west side of the dock is intended for the import trade, the south-east is to be devoted to coal shipments exclusively, the Lewis-Hunter loading tips being provided.

The Parliamentary Committee made havoc of some of the collateral lines of the Bute Dock Bill. It refused permission to straighten and divert the river Taff, and it declined to grant an extension of the Dockmaster's sphere of control. It left, however, a great work to be executed, free of further legislative interference, at a cost which was originally estimated at about £650,000, and which engineers who know the land say will take at least £1,000,000 to complete. Until now the actual excavation of the dock and lock areas has not been commenced. The preliminary works, which are in themselves extensive and laborious, were at the beginning of the month well under way. Since Springtime great headway has been made with the embankment which is to inclose the foreshore, and give a dry area, as far as may be, for the delving to the future dock bottom. Railways have been placed on this new ground, and also on the old ground ranging from what was aforetime known as the Low-water Pier. There are about three miles of railways, and the ordinary contractors' wagons are casting out from these lines on to the foreshore which is being reclaimed 1000 tons of slag and ballast per day. It may not seem much to say that 150,000 tons have been deposited since the engineers went to work; but it means an entire transformation of the aspect of the shore line from the channel within a short twelvemonths of time.

There are great works going on, in the same neighbourhood, at Barry. The Barry Railway Company was again to the front early in the year with a proposed extension of its own line, and as the supporters of another scheme for a new railway, right across Glamorganshire, into a part of the Monmouthshire coalfield which had hitherto been a "preserve" of the Rhymney and Brecon and Merthyr companies, with the Great Western and London and North-Western as co-operative participators in the trade. The East Glamorgan Railway, as the new line was called, started from Barry and came back to Barry. It would not only bring Barry Dock into touch with a number of important collieries at present served solely by the Taff Vale or Rhymney, and enable it to "tap" the traffic at present sent to Newport for shipment; it would also benefit the passenger business of the Barry Railway by giving it direct communication, *viâ* the London and North-Western, with the Midlands, Lancashire, and the North. That bold measure suffered discomfiture at Westminster; but, according to all reports, and to use the Doric remark of Mr. Archibald Hood, the vice-chairman of the Barry Company, the scheme is "scotched, not killed." It is to come up again, all being well, and in the view of the Barry Railway directors, "all being well" would indicate an assurance that they have with them in their new endeavour not only the support of the London and North-Western Railway Company, but the interested sympathy of one important local railway corporation, which opposed the East Glamorgan Railway at its outset. There is one thing about the Barry people which is ever commendable. Instead of resting upon their new-found prosperity they strike out new lines of enterprise. Disappointed of one auxiliary railway, the Barry directors are undertaking the financial responsibility for a line from Barry into the Vale of Glamorgan, and the coal measures on its north-western borders. They are also making a new dock, and this dock will nearly double the shipping accommodation of the port.

Among other dock and railway works deserving notice are those for the development of Port Talbot. Many earlier projects of a similar kind have centred in Port Talbot, which holds an exceptional geographical position, and since the opening of the Rhondda and Swansea Bay Railway has had a prospect placed before it which did not exist before. Here, in somewhat the same manner as with the new Bute Dock, it is intended to build two breakwaters, 270 yards apart, running about 350 and 530 yards respectively seaward from the end of the existing pier. Within these sea walls a dock is to be excavated 350 yards long by 198 yards wide, with an entrance lock 217 yards long, terminating in the river Avon. From the dock a railway is eventually to be made through a new mineral region, touching the Llynvi and Ogmore line near the Llynvi Ironworks, and not far from North's Navigation Collieries, and thence proceeding to the recently developed and reputedly rich Garw Valley, and there making a junction with the Garw branch of the Great Western Railway.

---

A PITTSBURG company proposes to build a rolling mill for the manufacture of structural steel, in which, the *American Manufacturer* says, electricity will be the power employed. This will be the first iron mill to be operated by electricity alone. The advantages offered in the way of cheap power by the company, which has fastened its dynamos to the floods of Niagara, will bring great industrial changes.

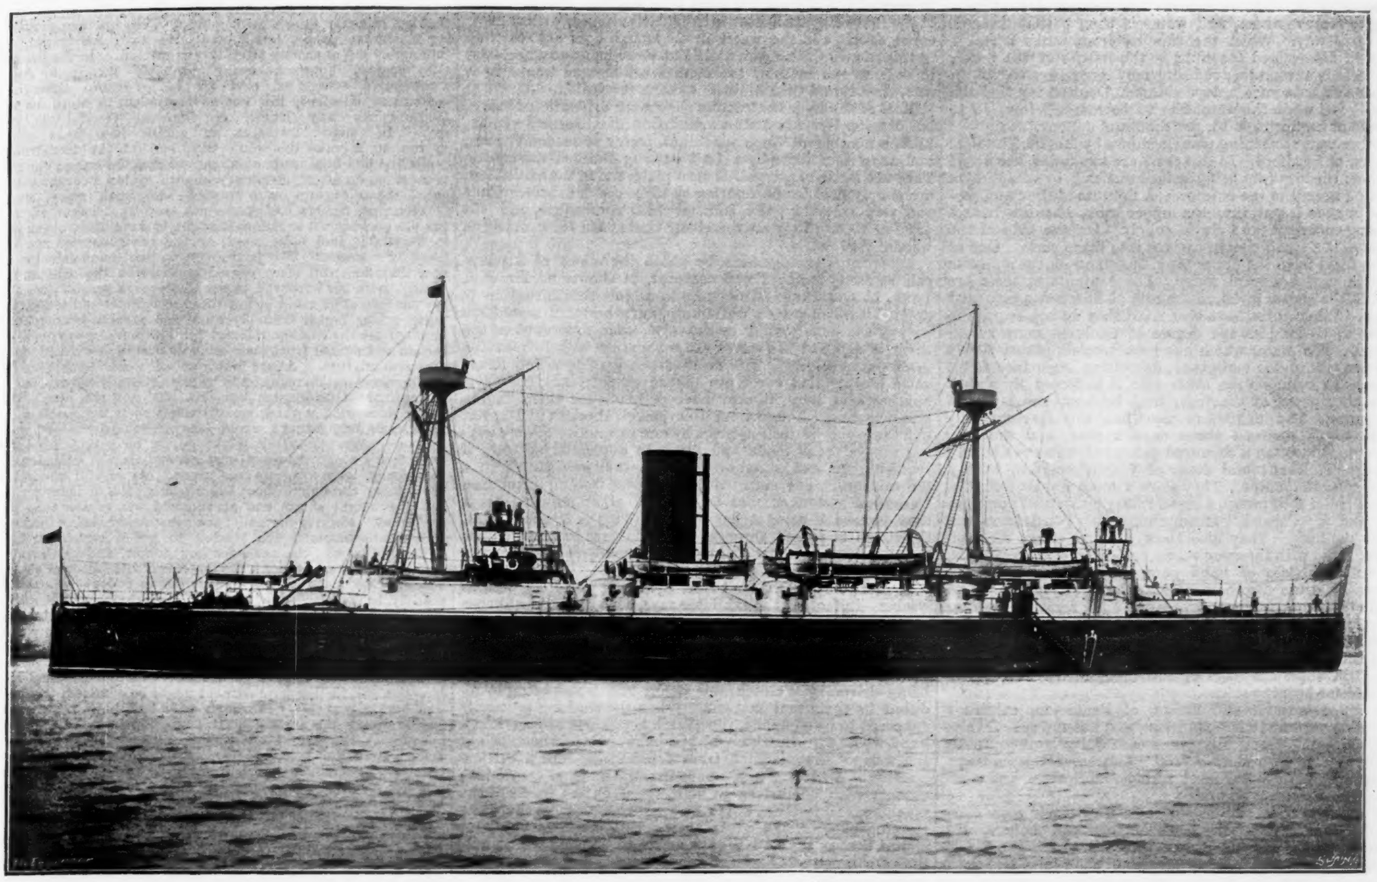
SIR W. G. ARMSTRONG, MITCHELL AND CO., NEWCASTLE-ON-TYNE, BUILDERS

*(For description see page 422)*



## A CURIOSITY IN BOILER REPAIRING.

The accompanying engraving shows an original and, we hope, unique example of misplaced ingenuity. The boiler was at work on a Scotch farm until a week or two since, when it was removed and replaced by a new one. It was employed in making steam for an engine constructed by Messrs. Carmichael, of Dundee, not less than 43 years ago. We are indebted to a correspondent for the photograph which we reproduce. The owner did not apprehend any danger. What would the verdict have been if the boiler exploded and caused loss of life? It is possible that some of our readers may be able to name worse cases, but we doubt it. We have seen the bottom of an old-fashioned box marine boiler held up with screw jacks bearing on the ribs of the ship, but the pressure was only about 8 lb. on the square inch, and the expedient was adopted as a last resource to get the ship into port. How long the boiler we illustrate had been at work with the front end supported by two wooden struts we are unable to say—apparently for some time, at all events.

## PROPOSED RAILWAY EXTENSION IN BARBADOES.

It is proposed to construct a light railway in Barbadoes, and we have received a copy of a report furnished by the consulting engineer, Mr. Walter Merivale, M. Inst. C.E., to the chairman and board of directors of the Barbadoes Railway. The author reports that he has completed the survey of the proposed circular light railway round the island. He estimates the cost of the extension from Belleplaine to Bridgetown, *viâ* Speightstown, at £65,000. These figures are based upon a preliminary instrumental examination of the ground, and represent the worst which the author expects to encounter.

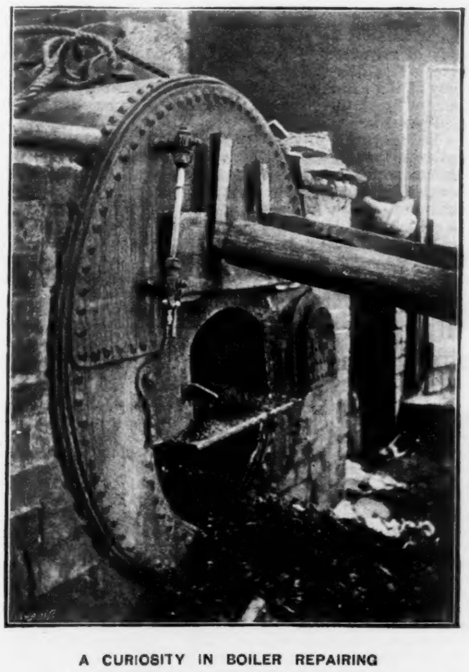
In the final scheme he suggests 2 per cent. as the ruling gradient, and 300ft. as the radius of the sharpest curve. Steel sleepers and 40 lb. rails are proposed as best suited to the requirements, and 14-ton six-wheel locomotive steam engines, with pony trucks in front and behind. All the rolling stock to be built with double bogies and trussed frames, otherwise more like tramcars than railway carriages.

Details are given as to the direction to be taken by the proposed line. Leaving Belleplaine Station the line would be along the public road for the first 1000ft., and in various other places it again follows the road. The author, however, points out that although a saving in first cost would be made by using the public roads, there are serious objections to it, which might entail much higher cost for maintenance. It appears that plantation land is valued at from £35 to £40 an acre, and land in small allotments at from £50 to £60 an acre, to which 25 per cent. must be added for compulsory sale.

The rolling stock would consist of four six-wheel 14-ton pony truck tank engines at £850 each, making £3400, and the rest of the rolling stock, consisting of eighteen open third-class bogie cars to seat forty-eight persons, two covered first-class cars to seat thirty persons, and various trucks, would cost £8940, being a total of £12,340. It appears that wooden sleepers are not considered suitable. Four stations are suggested, namely, St. Lucy, Speightstown, Holetown, and Bridgetown. The first three stations would each cost £200, and the last £300, very plain structures only being needed.

For land purchase the author considers £5500 would be sufficient. The bridges are to be of timber, although later on masonry might be substituted. The author, however, does not feel certain as to the desirability of using coral for railway work, as he has not had experience with this kind of rock.

Mr. Merivale insists upon the desirability of completing the circular railway, if possible, owing to the economy which would be obtained in construction and facility for dealing with the traffic. It would, however, entail the subscription of about £30,000 more capital. The total population of the island appears to be 182,306, of whom 43,000 are labourers, 22,229 domestic servants, and 27,693 artisans. The present line passes through the parish of St. Michael, with a density of 3753 persons per square mile, and various other parishes having a mean density of 835 persons per square mile. The proposed line passes through the same parish of St. Michael, and through other parishes, the latter having a mean density of 760 persons per square mile.



A CURIOSITY IN BOILER REPAIRING

About 58 per cent. of the people earn on an average less than £30 a year, about 36·8 per cent. are children and scholars earning nothing, and of the remaining 5·2 per cent. possibly 1000 earn over £500 a year, and 8000 earn less than £500 a year. It is probable that these facts account for the result, that although the average payment per passenger has been reduced from 21 cents to 6·2 cents, the revenue has been raised 15 per cent.

The total length of proposed extension is twenty-four miles from St. Andrew station to Bridgetown *viâ* St. Lucy and Speightstown. The cost is put down as follows:—Earthwork, £6750; bridges, £5400; ballasting, £4860; permanent way, £23,814; stations, £1500; level crossings, £300; rolling stock, £12,660; land and property, £5320; telephone, £192; engineering superintendence, £1524; and for contingencies, £3000; total, £65,000. It will be seen that the cost of the extension works out to about 7s. 9d. per head of the population. By the old system of tickets the line took about £12 a day from passengers. This by a new system was increased 15 per cent. The author puts down the gross revenue per annum as follows:—

| | |
|---|---|
| Passengers | £11,000 |
| Parcels | 1,000 |
| Goods | 8,200 |
| | 20,200 |
| Subsidy | 6,000 |
| | 26,200 |
| Working expenses 65 per cent. | 17,030 |
| | 9,170 |
| Interest on £65,000 at 6 per cent. | 3,900 |
| | £5,270 available for dividends. |

## THE LAUNDRY EXHIBITION, AGRICULTURAL HALL.

The Agricultural Hall at Islington is again opened for the exhibition of machinery and appliances connected with a special industry. Directly the brewing, distilling, and mineral water plant was removed, it was replaced by washing machines, hydro-extractors, ironing machines, and the other fittings of a modern laundry. This Exhibition, which opened on the 7th inst., and is to close on the 17th, is only the second under the present management; but it is proposed to continue it annually, and the date for 1895 has already been fixed. The Brewers' Exhibition only lasted for six days, whilst this is to remain open for ten, excluding Sunday. Possibly for this reason some of the exhibitors seemed to consider the first four days as preparatory, and were not even in full working order on Saturday afternoon. This is not fair to the majority, who had responded to the appeal of the promoters, Messrs. Cordingley, and were ready for the public on the first day.

Most of the appliances shown are especially designed for laundry work, though some of these, such as, for instance, the hydro-extractors, are used in other industries. Amongst the exhibits of more general interest, there are two sets of water-softening apparatus. One of them forms the principal feature of Messrs. Doulton's exhibit. There are many businesses in which a good supply of soft water is essential, but nowhere is it more needed than in a laundry. Messrs. Doulton's exhibit consists of a series of galvanised iron tanks. Lime is thrown into the first of these tanks, and the hard water which runs into it turns a small galvanised overshot wheel, causing stirrers in the first and third tanks to revolve. A concentrated solution of lime flows from the first tank into the second, where the excess of lime is allowed to settle. The third tank contains a solution of ordinary soda ash. The hard water flows into a cistern at a lower level than these three tanks, and is there mixed with the requisite proportion of lime water, and afterwards into another tank, where the soda solution is added. It is finally filtered through sponges held between perforated plates. The arrangement for cleaning these sponge filters is novel. The upper plate can be pressed down by a hand-wheel, so as to squeeze the sponges dry without having to remove them, and water is then passed through the reverse way. When the supplies from tanks 2 and 3 have been determined according to the nature of the water, the process is automatic; it being only necessary to put in the lime and soda once a day. Messrs. Doulton say that the cost of these, when the water has to be reduced from 18 to 3 degrees of hardness, is 1d. per thousand gallons.

Another water softening plant is shown by Messrs. Thwaites Brothers, of Bradford. In this there are two tanks, one above the other; the lower one being divided vertically by a diaphragm extending nearly to the bottom. A mixture of lime and carbonate of soda is put into the upper tank, about a bucket full being sufficient for a day's supply. On the side of the apparatus is a small cistern divided into three parts. One of these is filled from the upper tank, and that on the opposite side with ordinary hard water. The contents of these are mixed in the centre division, the rate of flow being regulated by taps. When these have been fixed they do not require to be altered, as long as the degree of hardness remains unchanged. The water which has been treated, passes slowly down one side of the main tank, depositing impurities at the bottom. In rising on the other side, it is forced through a strainer composed of shavings, held between two layers of wire gauze. The exhibitors say that the shavings only require to be renewed about once a year, and that the apparatus will soften a thousand gallons of water per hour.

Messrs. J. Evans and Sons, of Wolverhampton, have a good display of pumps. They show a small duplex pump, a vertical boiler feed pump, a small rotary gun-metal pump for milk, and a "Cornish" steam pump with Tonkin's valves, (tappit motion). They also show a small steam air compressor, fitted with the same valves, some Pickering governors, and different sizes of hand pumps. At the same stand, Messrs. Meldrum Brothers, of Manchester, have a full-sized model of a furnace, to burn breeze and dust, arranged to show the action of their steam jet blowers, in which the steam is forced at a great pressure through a nozzle $\frac{1}{16}$in. in diameter, into a tube under the fire-bars, and draws air with it. The same firm show drawings of furnaces of this description, arranged for burning refuse.

Messrs. Lancaster and Tonge, of Pendleton, exhibit a novel slide valve. It is cylindrical, and has the cut-off valve inside it, being practically one steam valve working inside another. They also show several "Lancaster" steam traps, piston rings, with spiral steel springs, lubricators, and other accessories for steam engines.

No exhibition at the Agricultural Hall would seem complete without Messrs. Hindley's engines and boilers, the "Eagle" ranges and the Blackman ventilators. The Blackman Company are increasing the size of their fans, and show one of 6ft. diameter, capable of moving 60,000 cubic feet of air per minute. They also show a good arrangement of drying room; in this the space is divided by a partition, and hot or cold air can be blown into either side as may be required. Thus one compartment may be cooled, emptied, and refilled, while the drying process is continued in the other.

In washing machinery, one of the largest exhibits is that of Messrs. Summerscales and Co., of Keighley. Their largest washing machine is called the "Practical;" it is made entirely of metal, the outer cylinder being of steel, and the inner revolving drum of perforated brass. An automatic reversing motion causes the drum to revolve in the opposite direction every three or four revolutions. Liquid soap, soda, blue, &c., can be introduced without stopping the machine; and the temperature of the water can be varied from cold to boiling, or high-pressure steam can be introduced when required for disinfecting. Another exhibit at this stand is an ironing and finishing machine, 96in. wide. The object to be ironed passes over an iron roller covered with felt, and a concave segmental casting with smooth inner surface and steam-heated, travels in a direction parallel to the axis of the roller. The pressure of the roller against this can be increased or diminished at will, and the length of the reciprocating stroke is 4in. Similar washing and ironing machines are shown by other makers, differing only in minor points of detail. An interesting method of applying heat is shown in Messrs. Summerscale's shirt-ironer. The roller is hollow, and a mixture of gas and air is burnt in it. This necessitates three supply tubes, as besides the air which is mixed with the gas, there is a third tube to admit sufficient air to allow combustion to take place. Besides washing machinery, they show a fifty-gallon steam-jacketed cooking pan just made for the Chelsea Guardians.

The Keighley Laundry Engineering Company exhibit an ironing machine, in which the drum is made in a different manner from those of most other makers. It is 3ft. diameter, and 9ft. long, and like others is made of cast iron. But instead of being turned perfectly smooth, it is fluted, and it has also 17,000 holes $\frac{5}{8}$in. by $\frac{1}{4}$in. cast in it. It is covered with wire gauze, and the felt is then put on as usual. The makers consider that this serves to keep the felt dry, as the moisture can pass through it into the interior of the roll, instead of having to evaporate from the surface, and that better work is the result. They also show some gas-heated box-irons, in which the bottoms are of gun-metal. They say that various mixtures have been tried for this gun-metal, and that they are using a material which effects a great economy in gas.

An exhibit which is attracting a good deal of attention is that of Messrs. T. W. Barber and Co., of Queen Victoria-street, who show irons, &c., heated by electricity.

Messrs. R. G. Whitaker and Co. have a very varied selection of machinery, chiefly made in the United States. The principal feature of their exhibit is a self-balancing hydro-extractor. This machine, which runs at 1000 revolutions a minute, works very smoothly, being carried on an india-rubber washer 9in. diameter and 2in. thick. They also show several washing machines for steam and hand power. In all of these, the inner drum is made of pitch pine. The question whether wood or brass is preferable for these seems quite undecided. Wood is certainly cheaper, and Messrs. Whitaker say that hospitals prefer it, as many chemicals which corrode brass have no effect on wood.

Another firm who prefer wood to metal for the drums of washing machines, is the Blair Engineering Company, of Peckham, who exhibit a composite rotary washing machine, 4ft. 6in. long, by 3ft. 8in. diameter. They consider that the lightness of wood, as compared to brass or steel, causes the machine to run more easily, and that a wood-lined machine washes better, whilst as iron is used for the vertical parts and stays, strength is not sacrificed.

In the machines described above, and in several others, the drums are made of pitch pine; but in the "Eyelet Drop" washing machine, exhibited by Mr. J. A. Mawson, of Bolton, the drum is of oak. It is divided into four compartments, and perforated with 4000 holes, which are eyeleted with tin, to prevent the edges of the holes from fraying. The partitions of the four compartments are irregularly shaped, with angular corrugations, and the water in the trough does not reach up to the axle; by this means, without there being any necessity to reverse the motion, the clothes are thrown from side to side, rinsed, and then drained, at each revolution.

Most of the hydro-extractors shown are driven from below, but Messrs. Watson, Laidlaw, and Co., of Glasgow, who exhibit a number of these machines, prefer to suspend them, and drive from above by a shaft passing through the centre. They are made of galvanised steel plate, and in the exhibition, are simply held to the flooring by three coach screws. They run very smoothly, the 30in. at 1500 revolutions, and the 48in. at 1000. They are massively made, the 48in. machine weighing 48 cwt.

A very neat arrangement, by which the valves of a pump can be easily removed and replaced, is shown by Mr. J. J. Lane, of Old Ford. The pump to which this invention is applied is a belt-driven wall pump, and the valve seats form part of the same casting as the valve cover, so that when the cover is removed the valves are withdrawn with it from the main pump casting. The faces of the casting which forms valve seating and cover are planed at right angles to one another, and they fit into a recess made for them in the pump casting. A stud from this passes through the cover, and the whole is held in place by one nut. The cover carrying the valves is made and fitted in duplicate, so that, if requisite, one can be removed and another substituted in a few minutes. The same exhibitor shows ironing machines, Decoudun system, similar to those of other makers, except that, instead of using a flexible steam pipe or knuckle joint, the steam is passed through a spiral brass pipe, which has spring enough to allow of the four inches travel of the ironer, thereby preventing all risk of leakage.

A machine which serves as hydro-extractor as well as washer—in fact, as the exhibitor says, a complete washhouse in one machine—is shown by Mr. E. D. Reeve, of Wandsworth. The revolving drum is divided into three compartments, and is made of perforated gun-metal plates. When the clothes are first inserted, it is run as an ordinary washing machine, being driven by a clutch, the steam and water being introduced in the usual manner. When the washing process is supposed to be complete, the clutch is put out of gear and a hand-wheel turned, which, by means of a worm wheel, brings the axis of the machine from a horizontal into a vertical position. A friction cone above the clutch then comes into contact with one driven at high speed on the frame of the machine, and it then works as a hydro-extractor, the water running out through a tap at the bottom. The exhibitor claims that as the clothes have not to be handled whilst wet, they are much less likely to be damaged, and the saving of time is evident.

The heaviest washing machinery in the Hall is that shown by Messrs. Clements, Jeakes, and Co., of Great Russell-street. They have a Decoudun ironer 110in. wide, with steam-heated bed and roller, and resembling a huge lathe rather than a laundry appliance. They also show several very strong washing machines. One, which they say is the largest ever made, is of $\frac{3}{8}$in. steel boiler plate, and is 6ft. diameter; the drum being constructed of galvanised steel bars $\frac{5}{8}$in. diameter. This machine has been tested up to 150 lb. pressure on the square inch, and is especially intended for disinfecting large quantities of clothes. An over-hung hydro-extractor is stepped at the bottom in a phosphor-bronze bearing, and is intended to run at from 2000 to 3000 revolutions per minute.

Messrs. Harper Twelvetrees show a washing machine very similar to that described above, except that the drum is made of galvanised steel tubes $\frac{3}{4}$in. external diameter, and set close together. In another of their machines the periphery of the drum, and a central partition in it, are both made of brass tubes. They have also a large selection of hand-power machines.

A large number of machines are shown by other makers similar in type to those described, and there are also many exhibits which are of no special interest for engineers, though they help to fill the Hall, and conduce to a successful Exhibition. Amongst these may be mentioned a red marking ink exhibited by Messrs. G. G. Wolff and Co., of Haggerston, said to be identical with that used by the Egyptians over 3000 years ago. Certainly the exhibitors submit objects marked with it to very severe tests, such as boiling in caustic potash, without the colour losing its brilliancy.

## THE MODERN DEVELOPMENT OF THE GAS ENGINE.

An interesting paper on the above subject was read on Saturday last before the members of the Manchester Association of Engineers, by Mr. James Atkinson, M.I. Mech. E. The paper, which was illustrated by numerous diagrams, first dealt with three epochs of the "Otto" gas engines, of which three diagrams were given, showing the great reduction in the gas consumption which had been effected during the last fourteen years. The "differential" and "cycle" gas engine, invented by the author, were next described, after which the reasons for the recent greatly improved consumption in the Crossley "Otto" engine were explained and shown to be mainly due to the scavenging arrangement for getting rid of the burnt gases entirely, which was a recent invention of Mr. Crossley and the author. The means for getting rid of the burnt gases left in the cylinder at the end of the exhaust stroke were described in detail. By an alteration in the position at which the exhaust valve in an ordinary "Otto" engine would be closed and the admission valve would be opened, the improved engine was so arranged that for a quarter of a revolution the air valve and the exhaust valve were both open at the same time. The improved engine was fitted with a long exhaust pipe, an average length of about 65ft. being found the most suitable. When the exhaust valve was opened, there was some 30 lb. to 40 lb. pressure in the cylinder. The energy stored up in this cylinder full of hot gases was utilised in putting in motion a long column of exhaust gases in the exhaust pipe. When, therefore, the piston commenced to slow down, after the middle of the exhaust stroke, the column of gases being in motion caused a reduction of pressure in the cylinder, the reduction being accentuated whilst the crank was passing from one position to another, during which time there was a partial vacuum in the cylinder. Both the admission valve and the exhaust valve being open at the same time, a strong current of air was drawn through the end of the cylinder, sweeping out the burnt products and replacing them with pure air. It was, however, necessary to so shape the end of the cylinder that the burnt gases were completely swept out. As soon as the burnt gases were replaced with pure air, the gas valve was also opened, and an explosive mixture was drawn in during the suction stroke, the cylinder being thus filled entirely with pure air and combustible gases. The effect of this was shown by means of a diagram, which represented a mean pressure of 98·75 lb., and bringing the consumption of gas per brake horse-power per hour down to 16·487 cubic feet. This was an enormous reduction, being the greatest ever made by any single improvement in the gas engine, and the consumption was not more than half the amount required formerly. Incidentally there were other advantages in the improved engine. It was known that an ordinary type Otto engine, working for long periods at its maximum power, would not give as much power when thoroughly hot as shortly after it was started. In the improved Otto engine, however, owing probably mainly to such a considerable volume of cold air being drawn through the combustion chamber, this engine continued to work as satisfactorily for any length of time as it did on starting. In some instances an engine had been allowed to run on a brake the whole day, and at the termination a brake test had been made which proved that the engine was giving as much power as at starting, and with as low a consumption of gas. When engines were worked with weak gases, such as Dowson gas, trouble had sometimes been experienced when the gas was perhaps not so rich as it ought to have been, owing either to unsuitable fuel being used, or the gas generator not being properly managed. The mixture being too uninflammable gave poor diagrams, and often caused ignitions in the exhaust or air pipes. With the improved engine, however, a greater quantity of gas per revolution could be got into the cylinder and satisfactorily burnt, giving higher mean pressures, and practically complete immunity from the troubles referred to. Ignition also was made more certain and regular from their being no waste gases mixed with the explosive mixture. At the first glance it would be supposed that the improved engine required to be more strongly constructed than an ordinary Otto engine, but this was not the case. When gas engines were working unsatisfactorily—as, for instance, with the ignition tube rather too cold—they occasionally missed igniting a charge. Sometimes this might go on for several revolutions, until finally a cold charge of pure gas and air was ignited, and an abnormally large diagram was given. As several charges had been drawn through without being ignited, the cylinder was cold, and the weight of gas and air enclosed was greater than if the engine were working normally, the consequence being that under such circumstances it was possible to get a certain maximum strain which was the same for any engine, and this maximum strain was not affected by the improvements. It was therefore necessary to make all gas engines strong enough to stand this possibly heavy strain, so that, though a higher initial pressure was obtained in the improved engine, it was not necessary to strengthen any of the parts beyond what would in any case be required, the maximum possible strain being proportional to the compression pressure. The improved engine did not expand the charge beyond the original volume before compression, and in this direction still further improvement might be obtained, though this was hardly probable. A rough trial had been made with an engine closing the admission valve earlier, so as not to fill up the cylinder at the end of the suction stroke. From experiments made, there did not, however, appear to be any economy in reducing this charge, though it must be admitted that the trial was not made as completely as it might have been. They must bear in mind that, by increasing the expansion in this or any other way, a larger cylinder and engine per unit of power was required. Consequently, the mechanical efficiency could not be as good, and from a commercial standpoint cost of engine per unit of power was an important element. All things considered, and bearing in mind the excellent results obtained, it was very doubtful whether any material all-round gain could be made in this way.

In the discussion following the reading of the paper, Mr. Jenkins, after remarking that the costliness of gas retarded the introduction of gas engines, which might be very usefully adopted for a great many purposes, said he would like to know whether the increase of compression pressure from 40 to 79 had any detrimental effect upon the mechanical efficiency of the gas engines when working at reduced pressures. Mr. Guthrie thought the modifications and alterations recently introduced in the gas engine were sound in every direction. Mr. Fulton, commenting upon the introduction of the long exhaust pipe, said that if this had necessarily to be made straight, it would be impracticable in some situations where this could not be done. He thought that with this pipe the increased friction in the pumped-out air when getting away would tend to throw still more load upon the piston in expelling the air, and as to the method of getting rid of residual products, it might possibly happen that some of those products would, on the incharging stroke be drawn back from the exhaust pipe into the cylinder. Mr. Saxon observed that, in his opinion, the brake efficiency of a gas engine would not equal that of the steam engine. It was a very peculiar feature in Messrs. Atkinson and Crossley's gas engine that the exhaust opened so early and closed so late, and the getting rid of burnt gases was certainly effected in a praiseworthy manner. Mr. Craven, in giving some interesting particulars of the working of a 20-horse gas engine, made by Crossley, and developing 30-horse power, which he had put down in his works, said this engine drove a 15-ton overhead rope-driven travelling crane, and about forty machine tools of various kinds. The gas consumed in the engine was 500ft. per hour, and at 2s. 6d. per 1000 cubic feet, the cost equalled ½d. per horse-power per hour. Mr. E. Constantine observed that though testing by the brake was no doubt the right way, they must also consider the indicated horse-power. An Otto engine, consuming 14½ cubic feet of gas per indicated horse-power, cost about ·4d. per indicated horse-power per hour, taking the charge for gas at 2s. 6d. per 1000 cubic feet; whilst a steam engine, using 40 lb. of steam per horse-power, evaporating 8 lb. of water per 1 lb. of coal, would cost ·4d., at 15s. per ton of coal. A large cotton mill engine averaged ·138d., whilst a triple expansion engine, consuming 14 lb. of steam per indicated horse-power, and evaporating 9 lb. of water per 1 lb. of coal, cost ·125d. per indicated horse-power per hour. The President—Mr. Thomas Daniels—recommended the adoption of gas engines for separate bays in a locomotive or machine works. Mr. Atkinson, replying upon the discussion, said that with regard to the increase in compression from 40 lb. to 79 lb., he might observe that in the former case it was difficult to keep the slides of the engine right, and this necessitated a limit being placed to the compression pressures. When the slide was done away with, and the ignition tubes introduced, no difficulty was experienced in getting the higher pressures. The exhaust pipes in the present engine could be made with any reasonable number of bends, but no elbows must be introduced.

MEAT IMPORTATION.—The first successful cargo of chilled beef brought into London by a new line of meat-carrying steamers from Boston has just arrived at the Victoria Docks, in the s.s. Virginian. This vessel, one of the Leyland Line, has recently been fitted with a new refrigerating plant on the Linde system. The machinery is in duplicate, and the insulated holds, which will carry about 1600 quarters of beef, are cooled by means of a system of brine pipes. The machine very easily maintained the requisite temperature, even when only one half of the machine was working. The average of six thermometers showed a mean temperature of about 28¾ deg. At no part did the temperature fall below 28 nor rise above 29¼. The remarkable regularity of the temperature is of course a very great advantage in the transport of meat which must not be frozen, and which at the same time must be kept at as near freezing point as possible. The success of this cargo will no doubt lead to the importation of a considerable quantity of meat direct from the United States to London instead of coming through Liverpool.

## RAILWAY MATTERS.

The much needed harbour railway at Helsingfors has been completed at a cost of £81,500.

Mr. Wm. Purcell O'Neil, C.E., has been appointed by the directors to the position of chief engineer of the Midland Great Western Railway of Ireland entire system.

The necessary plans have been prepared for an ordinary narrow gauge railway between Civita Vecchia and Tolfa, possibly with the view of extending the line to Bracciano, but for the present the matter is left in abeyance.

Messrs. Allan, Whyte and Co., wire rope manufacturers, Rutherglen, have just shipped a cable for the Melbourne Tramway and Omnibus Company, Limited, the length of which is 18,000ft. It weighs over 18 tons, and it is the first rope for this purpose which has ever been made in Scotland.

A scheme is under consideration for the construction of a light railway from Menai Bridge or Llanfairpwyllgwyngyl to Beaumaris, Anglesea, and surveys of both routes have been completed. At present communication between Beaumaris and neighbouring towns is restricted to ferries and roads.

A landslip occurred on the 12th inst. on the Swindon and South Wales section of the Great Western Railway, 200 yards above Stroud, where the lines run on an embankment above the Thames and Severn Canal. The slip has been threatening for some weeks past, and during Monday night it was found that the down line of rails could not be used any longer. The traffic is therefore being worked entirely on the up rails. The down rails will soon be again ready for use.

The new railway from Rome to Viterbo, a distance of fifty-four miles, opens up communication with Bracciano, Vetralla, and Ronergtrone, the latter place being reached by a branch line from Caprancia, a distance of five miles. Some other interesting places from an artistic point of view, *i.e.*, Caprarola and Toccaretta, are rendered more accessible by the new line, and the ruins of Ancient Veii are reached from the station of La Storta, twelve and a-half miles from Rome.

A general classification of the accidents on American Railways in September last shows that the derailments continue to be a large proportion of the whole. The derailments from all causes were 62 per cent. of the whole, and the unexplained derailments were nearly 40 per cent. of these. The unexplained accidents of all kinds amounted to 33 per cent.

| | Collisions. | Derailments. | Other ac'd'ts. | Total. | p.c. |
|---|---|---|---|---|---|
| Defects of road .. .. .. | 0 | 15 | 0 | 15 | 11 |
| Defects of equipment .. .. | 8 | 14 | 4 | 26 | 19 |
| Negligence in operating .. | 25 | 11 | 0 | 36 | 25 |
| Unforeseen obstructions .. | 0 | 15 | 4 | 19 | 12 |
| Unexplained .. .. .. .. | 14 | 36 | 0 | 50 | 33 |
| Total .. .. | 47 | 91 | 8 | 146 | 100 |

The record of train accidents on American railways in September includes 47 collisions, 91 derailments, and 8 other accidents, a total of 146 accidents, in which 50 persons were killed and 126 injured. These accidents are, by the *Railroad Gazette* classified as follows:—Collisions: Trains breaking in two, 7; misplaced switch, 2; failure to give or observe signal, 6; mistake in giving or understanding orders, 3; miscellaneous, 15; unexplained, 14. Total rear collisions, 22; butting, 13; crossing, 12. Total, 47. Derailments: Broken rail, 3; loose or spread rail, 7; defective bridge, 1; defective switch, 3; bad track, 1; broken wheel, 4; broken axle, 6; broken car, 1; fallen breakbeam, 1; fallen deadwood, 1; failure of coupling, 1; misplaced switch, 4; careless running, 2; track repairers, 1; open draw, 1; bad switching, 3; animals on track, 5; landslide, 1; tornado, 1; maliciously misplaced switch, 2; malicious obstruction, 2; accidental obstruction, 3; unexplained, 36. Total, 91. Other accidents: Boiler explosion, 2; broken side rod, 2; cars burned while running, 1; other causes, 3; total, 8. Total number of accidents, 146.

The question of the linking-up of the narrow-gauge railway systems of northern India is one which is of the highest importance to the country, says the *Pioneer*, for through communication between trade centres without break of gauge is indispensable to the rapid development of trade. As was announced some time ago, Cawnpore is to be put in direct touch with the Bengal and North-Western system, the Gogra River being bridged. The work will be done presumably during the ensuing cold weather, as its progress should be as rapid as possible. The Government of India have agreed to the Secretary of State's proposals, and only details have now to be settled. This linking-up through Lucknow will not shorten the actual distance to be traversed, but it will obviate breaking of bulk in the goods traffic between Rajputana and the trans-Gogra districts. Salt from the Sambhu Lake will pass in one direction, rice, sugar, tobacco, and other commodities in the other. Once loaded in the wagons, these articles of trade will reach their destinations without having to be handled, as at present, at junctions between the broad and narrow gauge systems. The Government, however, have looked further afield than Bahramghat. They see that great advantages would follow upon direct connection between the metre gauge system administered by the Rohilkhund and Kumaon Railway Company and the Cawnpore-Achnera line. A line from Bareilly to Soron would open out a fertile tract of new country, and, in addition to avoiding break of bulk, would shorten the distance and materially cheapen the interchange of produce between Rohilkhund and Rajputana, at the same time facilitating transport of goods by providing an alternative route between Rohilkhund and the country north of Bareilly and the sea coast. The Bareilly-Soron line, therefore, will probably be undertaken simultaneously with that linking Cawnpore with the trans-Gogra districts, and thus the various metre gauge systems will be dovetailed together.

According to a recent report of the United States Consul at Chemnitz, the trolley system of electrical propulsion was substituted for that of horses on the city tramways a year ago. The wires are hung from the house walls instead of poles. The method of laying or stringing the wires is by rosettes fastened into the walls or woodwork of the houses, from which hooks, to which the wires are attached, project. In the case of wooden walls, large screws are turned into the wall; in the case of stone walls, a long jagged iron is driven in and cemented. These are then tested with at least seven times the weight that they are intended to bear; owners of property preferred to allow the use of their houses free for a year, to having a post on the sidewalk. The system is simple, cheap, convenient, easily adjustable, and free from much of the ugliness inseparable from the network of wires used for the trolley. The lines—as the law requires—are level with the pavements. This costs the company more money, but is infinitely better for the public. Accidents to wagons, carriages, and vehicles of all kinds are consequently rare. The gauge is narrow. The cars run at the rate of 220 yards per minute in the heart of the city, and 350 yards per minute in the suburbs, seldom if ever leaving the rails. The cars have no conductors, the motor man being the only person representing the company. The saving to the company thus effected amounts to £2200 a year. The fare is but 1½d. on all routes, including transfers. Fare boxes are attached to the front and rear parts of the car. The increase in traffic since the change from horse to electrical propulsion is said to be 60 per cent., notwithstanding a strenuous opposition for a long time to the change, and a year of exceedingly hard times. Public opinion was divided between the trolley-overhead and the underground system now working in Buda-Pesth. It was claimed, and pretty satisfactory proved, that in northern cities, where snow falls heavily and lies on the ground a long time, not only is the trolley best, but the underground system is not satisfactory.

## NOTES AND MEMORANDA.

The rainfall during September over some parts at least of the Thames valley was deficient to the extent of nearly 1in. The actual amount falling at Oxford was 1·74in., the average for twenty-five years being 2·66in.

The death rate of London declined last week to 15·0 per thousand annually, against an average of 16 9 for the thirty-three great towns. Preston's record was the worst, 28·8, and Birkenhead was the lowest with 11·8.

A recent number of the *Comptes Rendus* contains a paper on "Experimental Verifications of the Theory of Weirs, with either Adherent or Partly-submerged Watersheet, with regard to the pressures," by M. J Boussinesq.

The total number of supplies furnished by the London water companies during September was 810,471, representing an increase of 1269 supplies on the previous month. The total supply divided by the number of supplies shows a daily average of 231 gallons for each such supply.

The following statement of figures give, in the case of each London company, the number of gallons per head per day supplied during September:—Chelsea, 40·35; East London, 32·06; Grand Junction, 48·32; Kent, 29·36; Lambeth, 32·14; New River, 32·25; Southwark and Vauxhall, 37·96; West Middlesex, 32 67.

The Peninsular and Oriental Company's new steamer Caledonia has on her first voyage beaten the record. She arrived at Brindisi on Tuesday evening at 8.30 with the homeward Indian mails, which left Bombay on the 3rd inst. Her passage, therefore, from Bombay, including stoppages, occupied only ten days six hours, which is the fastest time hitherto made. Her mails will be delivered in London this morning, 12½ days after leaving Bombay.

At a recent meeting of the Paris Academy of Sciences, a paper was read "On the Superposition of Optical Effects of Several Asymmetric Carbon Atoms in the same Active Molecule," by MM. Ph. A Guye and M. Gautier. In a molecule containing several asymmetric carbon atoms, each of them acts as if all the remainder of the molecule were inactive. The optical effects of several asymmetric carbon atoms in the same molecule are algebraically added to give the optical activity of the molecule.

Dr. Froelich has published another paper, in which he endeavours to establish the law of the magnetisation of iron; he deduces the constants occurring in his law from a number of different observed results with different irons, and shows how the calculated and the observed values agree; he shows that good magnetic experimental data can always be represented by a formula with close agreement; the various coefficients determined for a number of different irons differ very considerably from each other, and those obtained from one set can therefore not be applied to another. He discusses the various methods for making measurements, and concludes that there is no doubt that the best method for obtaining the magnetisation curve is by means of a closed ring of iron.

The total number of the mines registered in Spain is over 15,000, of which only about 2000 are worked. The province of Biscay, however, still gains very considerable profits from its rich iron ore mines, as may be deduced from the fact that in 1893 out of a total production in Spain of 5,497,540 tons, the consular district of Bilbao was responsible for 4,918,650 tons; whilst in 1892 out of a total for Spain of 5,405,170 tons, the consular district of Bilbao furnished 4,573,560 tons. The exportation of iron ore from Bilbao to the United Kingdom in 1893 was over 3,000,000 tons, and as the total foreign import of iron ores into the United Kingdom was 4,065,863 tons—3,624,083 tons from Spain and 441,780 tons from other countries—it appears that shipments of Bilbao ores made up 84 per cent. of the importation from Spain and 75 per cent. of the total foreign importation of iron ores in the United Kingdom in 1893; and, calculating the yearly production of iron ores in the United Kingdom to be 14,000,000 tons, it would appear that Bilbao supplies about the fifth part of the iron ores yearly consumed in the United Kingdom.

The milling industry is the largest in the United States in point of capital and help employed. The *American Miller* says: "Our mills have ample capacity to convert into flour every bushel of wheat grown in this country, and, like the railroads and farming interests, the milling industry is spread over the entire country, being confined to no particular section. In 1835, flour represented 97 per cent. of the wheat exports from the United States. That per cent. has steadily declined until flour represents now about 30 per cent. of the wheat exports—a decline of 67 per cent. in the face of a constantly increasing capacity to manufacture flour in this country. In 1892, the wheat exports amounted to 225,665,812 bushels, of which 157,280,351 bushels went as raw material, and 68,385,461 bushels as the manufactured product. In 1893, the exports amounted to 191,912,634 bushels, of which 117,121,109 bushels was in the shape of raw material. Were it possible to export this as flour, the saving to our country would be from 8,000,000 dols. to 10,000,000 dols., the cost of manufacture. Of this amount the greater part would be paid out in labour."

A redetermination of the temperature of greatest density of water has recently been carried out by M. de Coppet, who gives an account of his results in the *Annales de Chimie et de Physique*. On account of the very slow change of density about that temperature, it is difficult to determine it within a hundredth of a degree Centigrade. The method adopted was a modification of that of Despretz. A number of thermometers were mounted in the lid of a cylindrical water vessel with their bulbs at various distances from the bottom, and symmetrically disposed about the axis. On immersing the vessel in a cold water bath, a current was set up, passing down along the sides and ascending in the centre. After a while the current stopped, and then was reversed. The course of the current could be followed by the readings of the thermometers. The water having the greatest density would sink to the bottom, and the temperature of the lowest bulb would be approximately that of greatest density. But the temperature at which the lowest thermometer stopped for a time was higher on cooling than on heating. *Nature* says, "The curves exhibiting the two series of changes are, however, symmetrical, and give the temperature of maximum density as 3·982 deg. by the hydrogen thermometer under a pressure of one atmosphere."

The structure of gold nuggets is the subject of a paper recently contributed to the New South Wales Royal Society by Professor Liversidge, F.R.S. Gold nuggets on being cut through, or sliced and polished, and then etched by chlorine water, were found to exhibit well-marked crystalline structure closely resembling the Widmanstatt figures shown by most metallic meteorites, except that in the nuggets the crystals are more or less square in section, and show faces which evidently belong to the octahedron and cube. On heating the nuggets in a Bunsen burner, blebs or blisters form, on both the polished and unpolished surfaces, and on still more strongly heating, these, in some cases, burst with sharp reports, and pieces of gold are projected with considerable violence. As no explosions have been observed on dissolving or eating away the crusts of these blisters by chlorine water, it would appear that the blebs are probably due to the vaporisation of some liquid or solid substance. As soon as a fresh supply of nuggets is obtained, experiments will be proceeded with to ascertain definitely whether gold nuggets contain occluded gases, or liquids, or solids which are vaporisable. In slicing some nuggets, scattered granules of quartz were met with inside, although quite invisible outside, and at first it was thought that the explosions might be due to the quartz; but the gas, in some cases, continued to issue from the burst bleb—where the aperture formed was small—and forced the Bunsen flame out into lateral jets, just as if urged by a blowpipe

## MISCELLANEA.

Mr. H. Johnson Phillips, F.I.C., F.C.S., late of the Great Western and Great Eastern Railways, announces that he has begun practice as an analytical and consulting railway chemist at Palace Chambers, Westminster Bridge, London.

We understand that Mr. Robert Zimmerman, who for the past ten years has been connected with the Germanic Company of Kiel, is about to leave that concern to take up the position of manager of the Vulcan Works at Stettin, the largest works of that class in continental Europe.

Mr. Alderman Robert Readhead has been elected for a second year to fill the position of chief magistrate of the borough of South Shields. Alderman Readhead is head of the engineering department in the well-known firm of shipbuilders, Messrs. John Readhead and Sons.

In his quarterly report of the health of Tunbridge Wells, Dr. Stamford, the medical officer of health, states that the deaths registered in the three months numbered only 81, being 16 less than in the corresponding quarter of last year, and equal to a death-rate of only 11·11 per 1000 of the estimated population.

The *Liberté* points out with satisfaction that the French cruiser Alger, which entered the Suez Canal on October 14th, several hours after the English cruisers Edgar and Spartan, has outstripped them, though it went *viâ* Obock, thus lengthening the voyage by 65 miles. It reached Saigon on the 6th inst., whereas the English cruisers only reached Singapore on that date, thus being 36 hours behind.

A Council of Ministers was held at Cairo on the 8th inst., the Khedive presiding. Mr. W. E. Garstin, C.M.G , Under Secretary of State to the Ministry of Public Works, presented a note in regard to the Nile reservoirs, which the council approved. In this note Mr. Garstin proposed to construct the dam at Assouan at a lower level than was formerly decided upon, in order to prevent the Philæ and other temples from being submerged. He also suggested that Mr. Willcocks should be sent to England to consult Sir Benjamin Baker regarding the final details of the plans. Mr. Garstin asked that money should be provided in next year's Budget to enable the Department of Public Works to commence supplementary works connected with the reservoirs next year. Mazloum Pasha, the Minister of Finance, undertook that this should be carried out.

Professor Mendelaieff calls attention in the *Novoe Vremya* to the great development of Russian industry during the reign of the deceased Emperor, who adopted the protective system exemplified by the Tariff of 1891. The articles specially protected were cotton, iron, precious metals, coal, salt, and timber. The production of these articles increased and gave an impetus to business in all directions. In 1880 the total of Russian industries amounted to 1,220,000,000, roubles, in 1890 to 1,660,000,000 roubles, and at present this total cannot be less than 2,000,000,000 roubles. The *Times* St. Petersburg correspondent says the whole production of grain in Russia does not exceed 2,000,000,000 poods, which in money is hardly a third of these figures, so that Russia's industries are now worth more than her agriculture. On agriculture alone Russia could not exist.

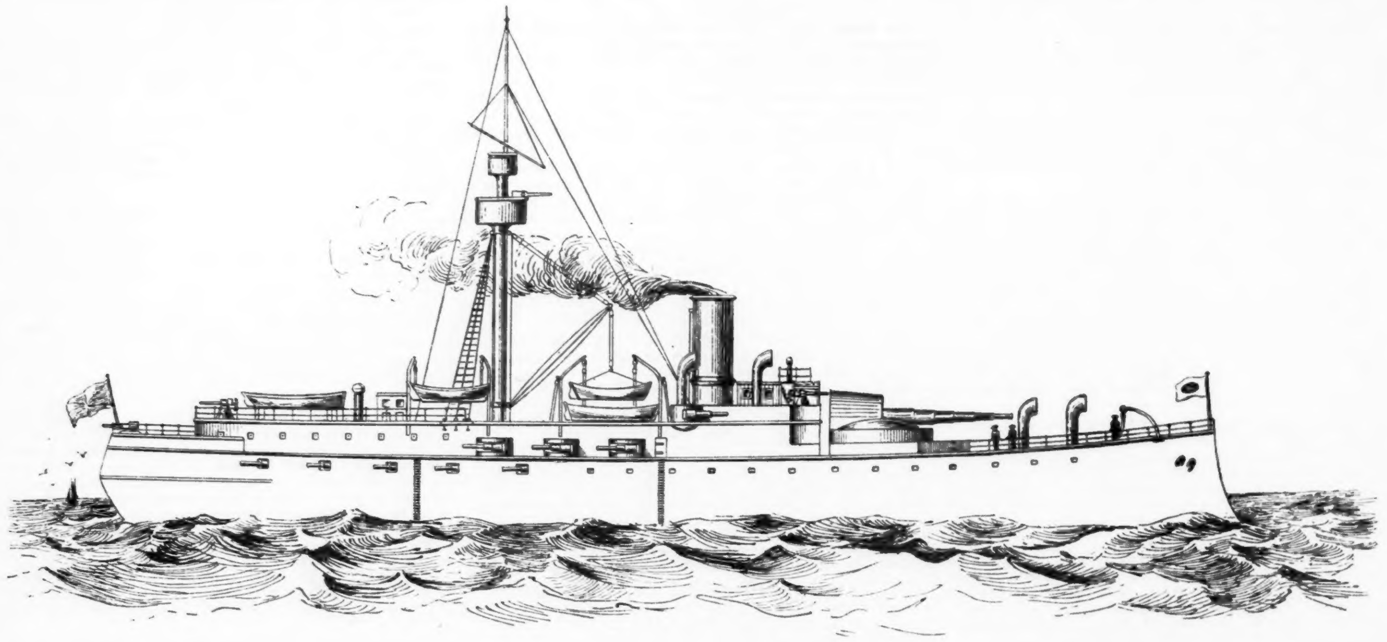
If the American farmer acts on the following there will be a little chance for the English wheat grower. The present crop year in the United States has shown that the farmers in the country, tributary to Duluth, have made up their minds that there is no money in raising wheat at prevailing prices. The *American Miller* says, they have also discovered that there are other cereals which can be raised with profit on the prairies of Minnesota and the Dakotas. This accounts for the large receipts of flax seed and barley during the past month. Last year during September the receipts of barley were 27,927 bushels. This season the receipts for the same period are nearly one-half million bushels. Last year in September there were received here about 38,000 bushels of flax seed, while during September of this year there was about 450,000 bushels received. Secretary Wyman, of the Board of Trade, estimates that the receipts from the 1894 crop, in both these grains, will be from two to four times as heavy as that of 1893. Prices for both flax seed and barley have been higher, considering the cost of raising, than of wheat.

During a preliminary trial of the torpedo-boat destroyer Ardent, built and engined by Messrs. J. I. Thornycroft and Co., and on two runs, one with the tide and the other against, a mean speed of 29 182 knots was obtained. The following are the principal dimensions of the Ardent and two other new vessels:—Length over all, 200ft.; breadth, 19ft.; depth, 14ft. The engines are similar to those fitted in the Daring and Decoy, being of the three-stage compound type, with two low-pressure cylinders. The diameters of the cylinders are—high-pressure, 19in.; intermediate, 27in.; and the two low-pressure, each 27in. The vessel is twin-screw. The boilers are of the Thornycroft water-tube type, and somewhat larger than those of the Daring and Decoy. An automatic boiler-feed control is used, and talc is used in place of glass for the boiler water gauges, the increased pressures now used necessitating a departure from the old gauge-glass. The power developed was about 5000-horse power, the boiler pressure being 210 lb. to the square inch, and the mean revolutions 407 per minute. The Admiralty was represented by Mr. W. J. Harding and Mr. Adams of the Controller's Department.

The Receivers of the Philadelphia and Reading Railroad have presented a petition for permission to negotiate a loan of £32,000, for the purpose of erecting an extensive coal-storage plant at Port Richmond. The plant will be located on property to the north of the present track at Port Richmond, which covers an area of 600ft. by 1800ft. The coal-storage plant will consist of six coal-trimming or piling machines; two of 20,000 tons capacity, two of 30.000, and two of 40,000 tons, making a total capacity of 180,000 tons, which may be increased by chuting to about 200,000 tons. The plant will be adapted to receive and store coal at the rate of between 5000 and 6000 tons in ten hours, and by the use of reloaders coal can be taken from stock, screened, and loaded into cars at the same rate. The plant to be erected is guaranteed to store and reload the coal at a cost not exceeding 2·5d. cents per ton for both operations. The difference between this cost and the present cost of handling coal at Port Richmond will, it is estimated, effect a saving of about £8000 a-year. The new plant will be erected by the Dodge Coal Storage Company, of Philadelphia.

A singular accident is reported to have occurred shortly after one o'clock on Saturday last. A horse attached to a brougham was being driven along Cannon-street, and on turning into Budge-row the animal began to tremble violently and immediately afterwards fell down. When the coachman, George Clark, got off his seat, he at once received an electric shock, but sustained no injury. The horse, however, died in a few moments. Directly afterwards two explosions occurred simultaneously in the Electric Lighting Company's junction boxes opposite No. 22, Budge-row, and in Cannon-street, facing No. 22, Walbrook. The latter premises are occupied by a hosier, whose shop window-blind was damaged, the basement window being also broken. The explosion forced off the covers of both boxes; and part of the brickwork and iron frame of the box in front of the shop was considerably damaged. A portion of the footway and kerbstones was blown into the carriage-way, striking and injuring two men. Others were taken to hospitals and found to be suffering from shock. A few seconds after the explosion dense smoke was seen issuing from the junction box opposite No. 22, Budge-row. The officials of the Electric Lighting Company will report the circumstances to the Board of Trade.

# JAPANESE CRUISERS MATSUCHIMA AND ITSUKUSIMA



## JAPANESE WAR VESSELS.

We engrave this week illustrations of two classes of Japanese cruisers, the one representing the Naniwa and Jakachibo, the other the Itsukusima and Matsuchima, all four of which were present at the recent naval engagement off the Yalu River, and with the exception of the Matsuchima, which was disabled during the action, are now employed in the investment of Port Arthur. The Hasidate, which was also at Yalu, is at the same time practically represented by the engraving of the two larger vessels, as she is a sister ship of the same dimensions, build, and tonnage, only her barbette is aft instead of forward, she having been built at Yokasuka in Japan, and completed only at La Seyne, near Toulon. The others were built and completed at La Seyne.

The principal dimensions, &c., of the Naniwa and Jakachibo, built by Sir W. G. Armstrong, Mitchell, and Co., are as follows:—Length, 300ft.; beam, 46ft.; draught, 18ft. 6in.; displacement, 3650 tons. The vessels are constructed of steel throughout. Over the entire length, and covering the machinery, boilers, magazines, and steering gear, there is a strong protective deck about 3in. thick, extending amidships from 1ft. above the water-line to 4ft. below. The hull is divided throughout into numerous water-tight compartments. The ships are fitted with two military masts, mounting two machine guns behind shields in each top, but no sails are carried.

The armament is placed on the upper deck, and is powerful. At the bow and stern two 35-calibre 10in. 28-ton breech-loading guns are mounted on revolving centre-pivot carriages, giving an uninterrupted arc of fire of 240 deg. The mountings, which were designed at Elswick, presented many novel points when completed. The training is effected by means of hydraulic engines placed directly under each gun beneath the protective deck, so as to be secure from injury. A shaft is led up to the deck and engages by means of a pinion in a rack fixed to the base of the revolving carriage. There are two engines to a gun, each capable by itself of performing the rotation—a duplication of parts which greatly diminishes the risk of accident. The working platform, which is in rear of the gun, provides space for the crew and contains the mechanism connected with the elevation and training; it revolves with the carriage, the crew being sheltered by a steel shield. The carriage is fitted with Vavasseur compressors, and the gun, after discharge, returns automatically into position of firing. The elevation is easily performed by simple gearing, whilst the loading is carried out at a fixed station placed amidships and protected by stout steel armour, within which are situated the hydraulic rammer and hoists for the charges and projectiles. Spaced along each broadside, on sponsons, are six 6in. 5-ton breech-loading guns, also of 35 calibres in length, with a horizontal range of 130 deg., mounted on Vavasseur centre-pivot automatic carriages, covered by steel shields, and along the upper works, at every available space, are placed ten Nordenfeldt machine guns. On the ends of the bridge are situated two 6-pounder quick-firing guns. There are four torpedo tubes.

A conning tower of steel armour stands on the forward bridge, and within it are placed the engine-room telegraphs and various voice tubes, the hydraulic steering-wheel, the directors for simultaneous electric firing of the guns, &c.

Four powerful arc lights are placed on elevated stations at either end of the forward and after bridges, capable of covering with their rays the entire space surrounding the ship. The engine-rooms, stokeholds, magazine and shell-rooms, and other compartments below the protective deck, are illuminated by incandescent electric lamps, as are also the coal bunkers on that deck and the captain's state-rooms. The total coal stowage is 800 tons, capable of driving the ship about 9000 miles at a speed of 13 knots. The number of officers and crew is about 325.

At the official trials of the Naniwa and Jakachibo, respective mean speeds of 18·72 knots with 7235 indicated horse-power, and 18·77 knots with 7120 indicated horse-power, were obtained.

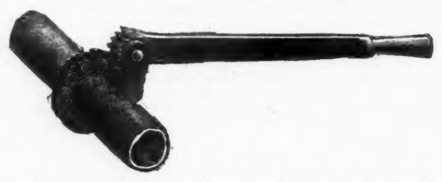
The Itsukusima, which may be described as representative of her class, has the following principal dimensions:—Length, 295ft.; beam, 50ft. 10in.; mean draught, 21ft. 2in.: two propellers; displacement, 4277 tons. Neither of these three cruisers carry any side armour, but there is a steel protective deck 2in. thick, which rises amidships and in the centre-line of the vessel, but slopes very much forward and aft. The barbette has steel armour, and the sponsons are similarly protected.

The main armament consists of one 32 cm.—12½in.—Canet gun, in an armoured barbette 12in. thick, forward, having an armoured trunk beneath for the ammunition hoists, which descends to the magazines. The secondary armament consists of eleven 12 cm.—4¾in.—Elswick quick-firing guns, eight of which are disposed in steel shield-protected sponsons upon the upper deck and superstructure with a very considerable arc of training on either beam, one astern and the other two pointing ahead. It was the presence of this enormously powerful battery of Elswick quick-firers upon the Itsukusima, Matsuchima, and Hasidate, which practically decided the current of events in the action at Yalu. The co-operation of the Yoshimo added, too, a most valuable assistance with her four 6in. and eight 4·7in. quick-firers of the same description. The hail of projectiles rained upon the Chinese vessels by these forty-five secondary quick-firers must have been truly awful in its effects. The lighter armament of the Itsukusima class consists of five six-pounder, and eleven three-pounder Hotchkiss guns upon the broadsides and superstructure, and six machine guns, some of them in the armoured tops. Four torpedo tubes are carried.

The Itsukusima has a maximum indicated horse-power of 5400, giving a speed under forced draught of 17·5 knots. She has one military mast with two armoured tops, one of which contains a search light, and a steel-armoured conning tower forward, which contains the engine-room telegraphs, voice tubes, &c. The whole of the well beneath the water-line is minutely subdivided into water-tight compartments.

## A SMOOTH GRIP PIPE WRENCH.

The illustration below represents a pipe wrench, for which the chief advantages claimed are, firstly, a smooth surface in contact with the pipe, certainly a valuable feature when used for galvanised pipe work, where the coating might be and often is destroyed by the ordinary tooth grip; secondly, it binds the pipe uniformly, and is therefore not liable to bulge or distort it. We think these qualifications alone should recommend it to users. Its action is obvious. One tool will take a number of sizes. The makers are Messrs. Lumsden, Smart, and Co., Bankwell-lane, Gateshead-on-Tyne.



## THE BACHELDER INDICATOR.

The steam engine indicator illustrated by the accompanying engraving is made by Messrs. Thompson, Bushnell, and Co., New York, and is being introduced into this country by Messrs. Rooper and Harris, Emery Works, Stafford. The object of this invention is the simplification of the indicator and reduction in the number of springs necessary to each indicator for a large range of pressures. A flat spring is used in place of the ordinary coil or spiral spring, and the indications of this spring are varied by varying the length free to bend under the influence of the steam pressure on the indicator piston. The indicator is shown in our engravings in section in Fig. B, and complete in Fig. A, with the exception of the removal of a milled nut or cover, which gives access to the piston for oiling. Fig. C shows one of the springs used to half full size. Two of these springs are sufficient for the full range of pressures usually met with in practice. By reference to Fig. B it will be seen that a horizontal cylindrical chamber projects from the piston cylinder, and carries an adjustable gripping piece and set-screw, by means of which the free end of the spring may be varied in length, and thus the pressure necessary to bend it through a given range also varied. The springs are calibrated in the instrument, and a pointer on the gripper piece slides in the index slot shown in Fig. A, by means of which the length of spring may be set to suit any pressure within the range of the one spring. The diagrams obtained by means of this indicator are much the same, even at high speeds, as those obtained by better known instruments. It is nicely made, the working parts being very light. The difficulty with the instrument is, of course, that introduced by the variation in flexure of the spring, which is not proportional to the variation in length of the free part, and to the difficulty in making the desired variation in sectional area.

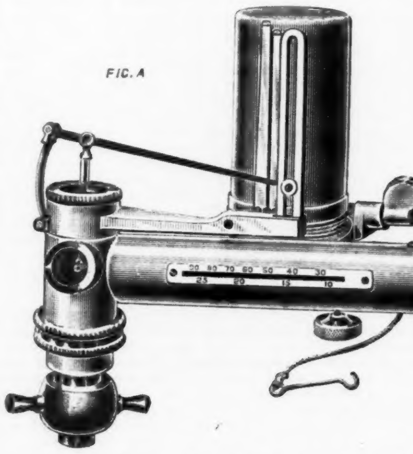


FIG. A

Although the spring is fixed by the sliding gripping piece, the flexure from the gripping point is not that of a parallel flexible bar rigidly held at one end, inasmuch as the flexure of the free part affects that part which is between the gripper and the pin fixed end. The character of the flexure is thus complicated as compared with that of ordinary flexible bars of different lengths. This, of course, makes it necessary to calibrate these springs for each instrument, and to do so by slight modification of their section or to compensate for it by use of constants. Once correct they no doubt remain so, but, of course, the difficulty of obtaining correct indications by the same spring at different lengths for any considerable range is not a small one, and some engineers who use their indicators for varied work may still prefer the larger number of separate springs required by the ordinary indicators.

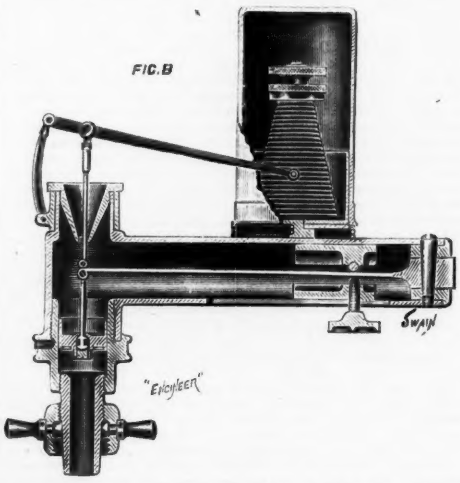

FIG. B

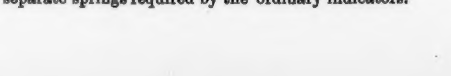

FIG. C

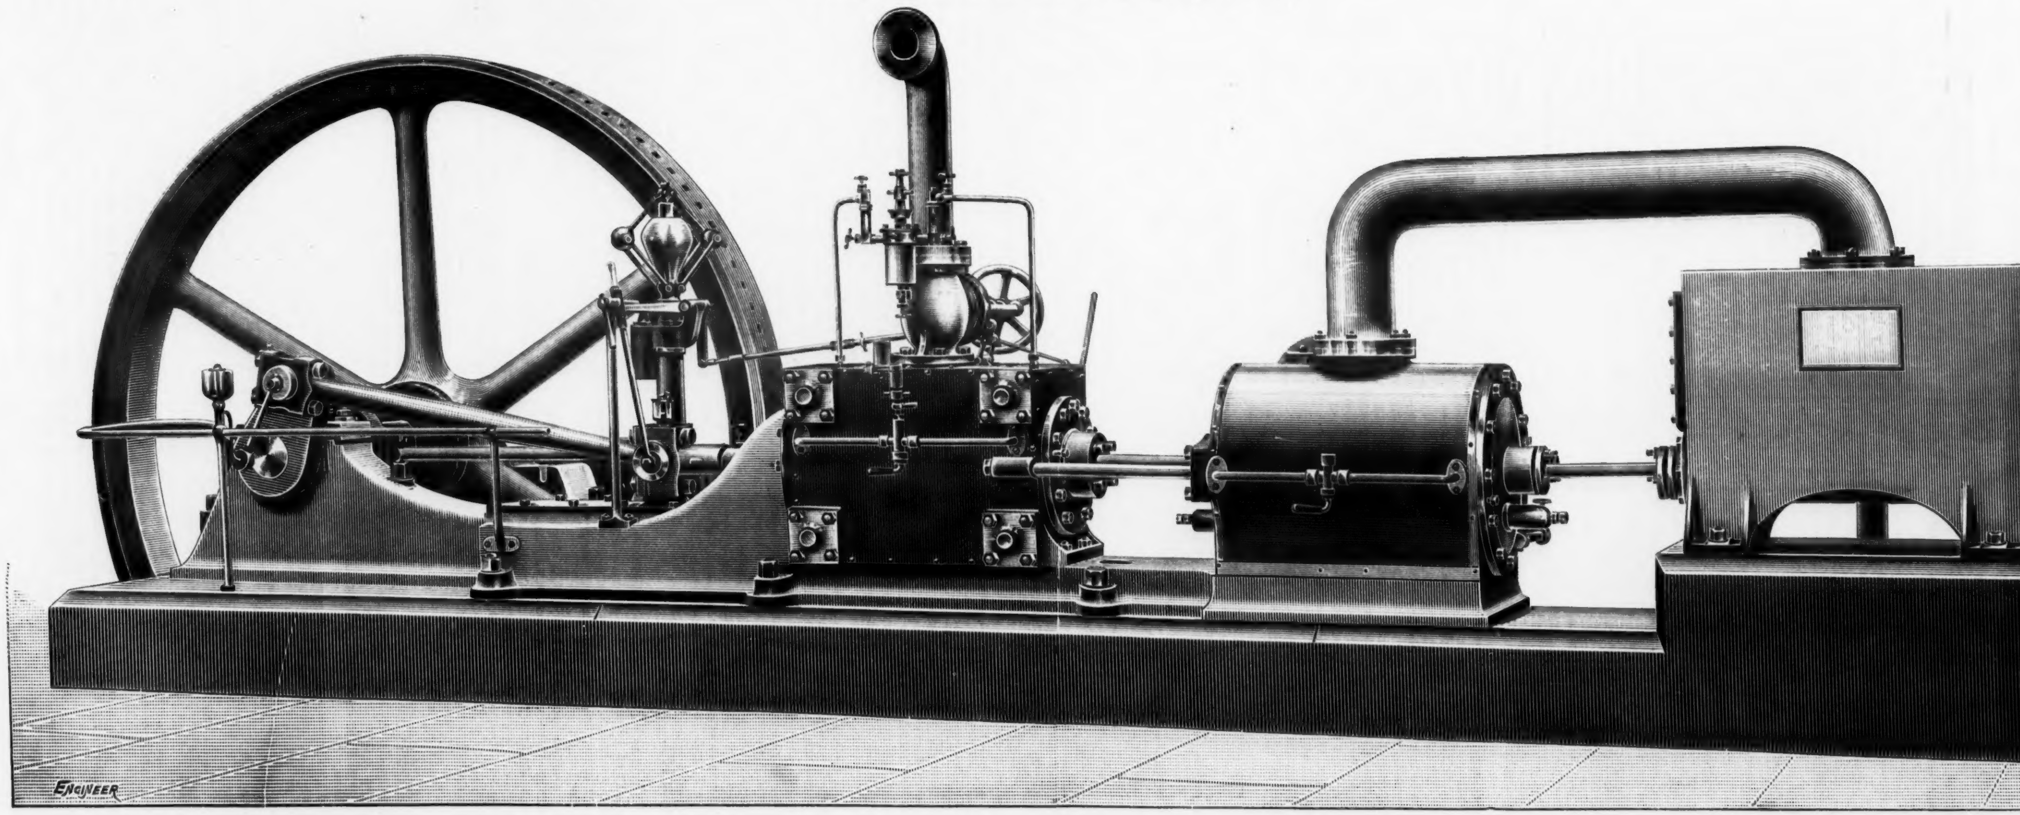
# HORIZONTAL COMPOUND MILL ENGINE

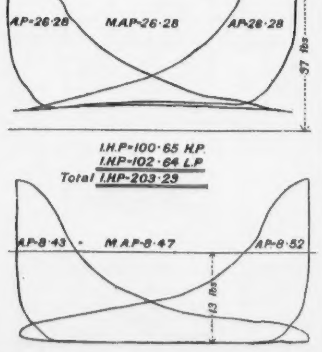
MESSRS. VICTOR COATES AND CO., BELFAST, ENGINEERS



## COMPOUND MILL ENGINES.

The engine illustrated on page 426 has a high-pressure cylinder 18in. diameter, and a low-pressure cylinder 32in. diameter, each 3ft. stroke, and is designed to indicate 350-horse power when running at ninety revolutions with 100 lb. boiler. Both cylinders are fitted with Corliss valves to steam and exhaust, the steam valves being actuated by Dobson's cut-off motion, that on the high-pressure cylinder being controlled automatically by governors, the cut-off on the low-pressure cylinder being regulated by hand so as to equalise the power on each crank. The Corliss valves have their spindles at right angles to the crank shaft, the cylinders being bolted together with a receiver between them; the high-pressure cylinder exhausting directly into this receiver, and the low-pressure cylinder taking its steam directly from it without having to pass through the usual connecting pipes, which, Messrs. Coates hold, cause an undue loss by wire-drawing and cooling the steam.

The double-throw crank shaft is built of steel, the body and pins being 8in. diameter. The pulley shaft is also of steel, and has bearings 9in. by 18in. All the main bearings of the crank shaft are lined with white metal, the bushes being made with round backs for easy withdrawal. The crank pin ends of the connecting-rods are of cast steel lined with white metal. The crossheads are guided by large slippers lined with white metal, and arranged for easy inspection without dismounting the guide slips or crosshead. Metallic packing is fitted to both piston-rods, and also to all the valve spindle stems. This packing is a great improvement as compared with fibrous packing, as the friction and resistance to the spindles turning being constant, lighter springs can be used in the dashpots. The air pump is worked off the crosshead of the high-pressure engine, and is placed sufficiently above the floor to permit of easy examination of the valves and bucket. The governor is of the quick-speed Porter type, driven by bevel wheels off the end of the crank shaft. The rope pulley is 12ft. diameter, grooved for ten 1¾in. ropes. The sides are sheeted with pitch pine, and spur teeth are cast on the circumference for engagement with the teeth of the automatic barring engine. The cylinders are covered with composition, felt, and planished blue steel, and fitted with the usual indicator and drain cocks and escape valves, and lubricated by means of double sight-feed lubricator, one pipe being taken to each cylinder. The main stop valve is fitted with a pilot valve in the centre to reduce the pressure required for opening it. We give herewith a set of diagrams taken from this type of engine when driving 200-horse power. These diagrams are, it will be seen, very good; the low-pressure being exceptionally excellent.



The horizontal tandem engine, illustrated above, 100 indicated horse-power, has a high-pressure cylinder 12in. diameter by 24in. stroke, fitted with Corliss valves, actuated by Dobson's cut-off motion and controlled directly by governor. The low-pressure cylinder is 20in. diameter by 24in. stroke, fitted with an ordinary D slide valve. The governor is of the quick-speed Porter type, driven by two ⅝in. ropes off a pulley on the crank shaft. The air pump is double-acting, with a barrel lined with brass, and having a brass bucket and rod, worked by a prolongation of the piston-rod. The suction and delivery valves are of india-rubber and of large area for working at quick speeds, usually 100 revolutions per minute. The framing is arranged for a slipper guide, and the crank shaft bearing has vertical and horizontal adjustment, and is lined with white metal. The fly-wheel is usually made for rope driving, and is then 10ft. in diameter, with six grooves for 1¼in. diameter ropes. The cylinders are neatly covered with blue sheet steel, and are fitted with the usual indicator cocks, &c., and oiled by means of sight-feed lubricator. These engines are made from standard patterns of 200, 300, 400, and 500-horse power, and have a vertical or horizontal air pump as required.

---

Admiral of the Fleet Sir Thomas Symonds.—We regret to have to announce that Admiral of the Fleet, Sir Thomas Matthew Charles Symonds, G.C.B., died on Wednesday evening at Torquay. He was second son of Sir William Symonds, who died a rear-admiral in 1856, in his 75th year, was born on July 15th, 1813. Sir William Symonds was himself the distinguished son of a distinguished naval officer, Captain Thomas Symonds, who died in 1793; but Sir William is best remembered in the service as having filled from 1832 to 1847 the office of Surveyor to the Navy. In the early part of the present reign his ships were by all nations regarded as triumphs of naval construction, and the Columbine, 18; Pantaloon, 10; Snake, 16; Vestal, 26; and Vernon, 50, served as types of vessels which long remained favourites for their sailing qualities and seaworthiness. His son, Thomas Matthew Charles, entered the Navy in 1825, passed his examination in 1831, and was made a lieutenant on November 5th, 1832. In October, 1837, he was promoted to the rank of commander. In November, 1860, he became a rear-admiral, and in 1862 was made admiral-superintendent at Devonport, with his flag in the Indus. In 1867 he was made a K.C.B., having in the previous year risen to vice-admiral's rank; and in 1868 he was given command of the Channel Squadron. An admiral's good service pension, which he held for rather over nine years, was conferred upon him in 1870; and in 1871 he reached full admiral's rank. His last command was as port admiral at Devonport, where he served from 1875 to 1878, with his flag in the Royal Adelaide. Seven months after relinquishing this office Sir Thomas was, on June 15th, 1879, promoted to be admiral of the fleet; and less than a year later he was made a G.C.B. Sir Thomas Symonds used to take the greatest interest in the development of the navy, and was always a warm advocate for the increase of the fleet, concerning which he addressed numerous letters to the columns of The Engineer.

The Water Supply of London.—The average daily supply of water delivered by the London companies from the Thames during the month of September was 105,954,467 gallons; from the Lee, 45,278,547 gallons; from springs and wells, 36,465,576 gallons; from ponds at Hampstead and Highgate, 4575 gallons. The last is used for non-domestic purposes only. The daily total was, therefore, 187,703,165 gallons for a population estimated at 5,465,957, representing a daily consumption per head of 34·34 gallons for all purposes.

# LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

## GOVERNING ELECTRIC LIGHT ENGINES.

SIR,—I am afraid it is only since he saw Mr. Kuhne's illustrations that your correspondent's—Mr. Cameron—gear, has become free from the defect peculiar to single valve triple expansion apparatus, in which the valve lifters are closely confined by a bridle on the valve stem, for, although he now shows in his sketch the bridle as being lengthened, as in the latest Proell apparatus, it is only a week or two since I noticed in the *Mechanical World* an illustration of his gear, and that showed the bridle on the valve stem as closely confining the valve lifters. Nevertheless, as we cannot have the assurance that the defect never existed in his gear, we may take it for granted that the difference between the illustration I mention and the sketch he sent indicates that it will not exist in future.
JAS. DUNLOP.

240, Wallgate, Wigan, November 12th.

## BICYCLE MECHANICAL ENGINEERING.

SIR,—In an article relating to the Boudard gear for cycles—appearing in your issue of the 19th ult.—after a description of the mechanism it is remarked, "Why these additions are to make the propulsion of a bicycle easier is not shown." With your kind permission I should like to make the suggestion that a possible reason for this is, that in your illustrative diagram the chain wheel on the driver hub is shown as smaller than that on the crank bracket, while the reverse arrangement would be the correct one. In the machines I have seen, the former had ten teeth and the latter eight only. It is perhaps this arrangement that gives the Boudard gear its chief advantage. I should much like, however, to be permitted to point out several advantages which, I think, are to be obtained by the adoption of the principle of gearing up the bracket chain wheel.

The introduction of this principle permits of a larger chain wheel being mounted upon the hub of the driving wheel, without involving an abnormal increase in the size of that upon the crank bracket. It increases the rate of travel of the driving chain, but reduces the strain upon it in inverse proportion; with the important resultant advantage that the pressure upon bearings and consequent friction due to application of the driving power is thereby greatly reduced. The accompanying diagrams represent a machine with a 28in. driving wheel geared to 70in. The chain wheels are of 1in. pitch. In Fig. 1 the chain wheel mounted upon the driver hub has eight teeth and gears by chain with a 20-tooth wheel fast to the crank axle according to the usual method. In Fig. 2 a 16-tooth wheel is mounted upon the driver hub, gearing with one of the same size fast to a spindle running on the crank bracket, which, however, is by means of a suitable arrangement of gearing, made to revolve 2·5 times per revolution of crank. In the former case—Fig. 1—we have the chain moving slowly and subject to a considerable strain, while in the latter—Fig. 2—the chain travels twice as rapidly, but is subject to only half the strain.

Fig 1.

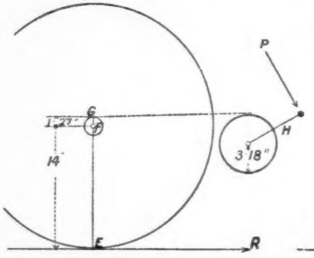


Fig 2.

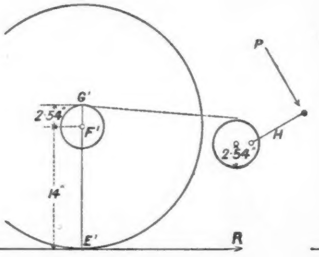

Fig 3.

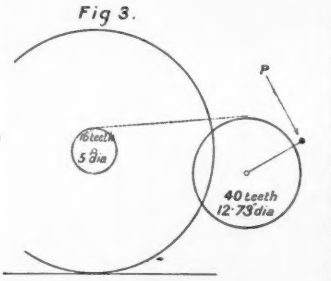


Without going fully into the theory of the distribution of the driving strain, it may briefly be observed that—with a given power applied to crank H—the length of lever arm F G—Fig. 1—being 1·27in., the radius of 8-tooth wheel, and that of $F^1 G^1$—Fig. 2—2·54in., the radius of 16-tooth wheel, and the other arms E F and $E^1 F^1$ the same in each case, the pressure upon the fulcrum F—Fig. 1—will be twice as great as that upon $F^1$—Fig. 2. The strain upon the bracket bearings will also be less in Fig. 2, as the geared-up chain wheel has in effect forty teeth, and a radius of 6·36in., as compared with the 20-tooth bracket wheel in Fig. 1, with a radius of 3·18in.

Of course, against this advantage of the geared-up bracket wheel there has to be set the unavoidable friction caused by the additional working parts, but if the mechanism is simple in design, well made, and fitted with ball bearings throughout, the friction due to it will be but little compared with the important reduction of friction elsewhere that has been referred to. When it is considered what has been accomplished on the geared front driver and also on the Boudard—although the latter is by no means all that could be wished—it must be evident that the friction due to gearing up need not be very serious.

Your correspondent "J. G. H.," in your issue of 26th ult., suggests that the same advantage possessed by the Boudard gear may be obtained by making the ordinary plain gear wheels larger, but to obtain the advantage of a 16-tooth wheel or driver by this means, one of forty teeth and as large as 12·73in. in diameter would be required on the crank axle, as shown in Fig 3. The smaller the ungeared crank chain wheel is made, the smaller must be the chain wheel on the driver, and the greater the frictional pressure upon bearings.

Another advantage of the system under consideration is that the increased velocity of chain and chain wheels causes a continuity of momentum when the machine is under weigh, producing an effect similar to that of a fly-wheel. This is admitted by all who have tried the Boudard gear, including adverse critics. It is found that a machine fitted with the gear can be driven up a short incline with less effort—when under weigh—than a machine fitted with the ordinary chain gear. That it has a steadying and regulating effect upon the pace is undeniable. It has also been found that the chain runs better on equal sized wheels, if not made too small, than upon wheels of unequal size; less slack being required to ensure easy running. Another minor advantage is that the larger rear wheel permits of the more satisfactory fitting of a protecting case for the chain.

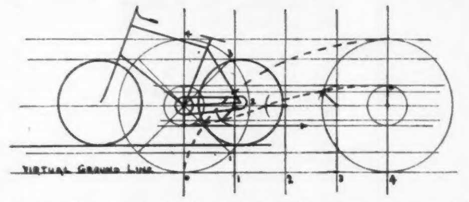
It is true, no doubt, that in bicycle construction, simplicity and fewness of parts are of very great importance; yet the simplest form or most direct method may not perhaps always prove the most efficient. If this were so, the front driver ungeared high bicycle would not have been superseded by the chain driven machine. The latter, however, although more complicated, is now the universal pattern, while the former has become practically obsolete.

I have little doubt that the Boudard gear, although in itself rather unsatisfactory, will prove to be the forerunner of an important innovation. While admitting, however, the merit of the principle involved in the Boudard patent, it is impossible to approve of all that is being put forward in support of it. In the prospectus of the company the opinion is given that the patent "establishes a monopoly commanding the whole trade, and laying every manufacturer under tribute," but this is altogether a preposterous claim, as it is pretty certain that whatever effective advantage is possessed by the Boudard gear may equally well be obtained by other arrangements of mechanism essentially different from those described in Boudard's specification. Already many designs have been produced, and among them it is very probable more than one will be found to be superior to the Boudard. An opportunity will, no doubt, be had of inspecting these at the forthcoming Cycle Trade Exhibitions at the Royal Agricultural Hall and the Crystal Palace.
RECORD.

Manchester, Nov. 10th.

## A BICYCLE PROBLEM.

SIR,—In reply to Mr. J. Harbottle's question in your issue of the 9th inst., the machine would move to the right, *i.e.*, backwards, in the direction of the motive force, the pedal revolving in a right-hand direction round its hub, but actually describing a prolate



cycloid with reference to the ground. This can be easily verified by experiment.
MARS.

Birkenhead, November 12th.

[We have received a large number of solutions, about one-half intended to prove that the bicycle will go forward. The other half that it will move backward. The preceding letter, however, covers the whole ground, and is correct. Whether the cord be pulled forward or backward, the bicycle will move in the direction of the pull.—ED. E ]

## LABOUR AND LUXURIES.

SIR,—I think it possible that your correspondents will find most of their objections dealt with in my letter of last week. In reply to "R. G. B." concerning Italy, I am not aware that I have said anything which applies specially to that country; I always have thought that its trouble was due, not to want of distributive powers, but to the want of gold to distribute. There is a very heavy debt, the interest on which is paid in gold; and it is credibly stated that nearly all the gold that goes into the country is taken there by tourists, and is sent out again to pay the interest. I have never said that gold sent out of a country can do the country good. That is entirely opposed to my view, which is, that the more gold there is in a country—I do not mean money, but gold—the better off and the more prosperous it will be. I am quite aware that this is not the view of many eminent political economists; but I think the whole progress of events, since the great Australian and Californian discoveries, proves its soundness.

Italy, like all agricultural countries, is poor; but I think your correspondent will admit that she is not so badly off as Spain which country does not maintain a costly army or navy. As to the reason why such a country as Italy is poor, I reply that it is partly because she has no manufactures, and no coal worth speaking about; and partly it is due to the national character. All Southern European countries are poor—Spain, Portugal, Sardinia, Italy, Greece, and Turkey—although the conditions as regards debt, armaments, &c., are widely different. But all this has really nothing to do with the functions of gold, as I have defined them. As to the wool corner in Australia, I have not heard that anyone in this country was injured by it, and I know that the whole affair was extremely popular with the wool growers of Australia, who profited by it considerably. Your correspondent fails to see that a rise in the price of a commodity must benefit someone. If, for example, he were engaged in trade, making steam engines, let us say, I take it that he would not object to a rise in the price of steam engines.
Y. X.

November 14th.

SIR,—So long as "Y. X." expects to find in the facts of business the simplicity of his unreal hypotheses, he is likely to mistake complexity for confusion. Gold has no economic powers whatever apart from human actions and desires. In what primer is this theory to be found?

He is "content with the assertion that as long as a sovereign changes hands often enough and quickly enough, the reason for the change matters nothing." Matters nothing to the gold perhaps, except for wear and tear; but to the community the reason for the change is the one material fact, not ethically or sentimentally, but economically; that is as affecting the production and distribution of wealth. Take his own favourite instance—robbery—it is notorious that production is hindered by the prevalence of robbery; that the more briskly gold passes from hand to hand by robbery, the less will be the production, and the less the total wealth of the community. Thus, on his chosen ground, the circulation of gold is not necessarily an economic benefit.

His answer to the question, "How can the production of more gold encourage trade?" might be instructive if he made it clear how, if at all, the case would be altered by supposing that A. finds in his rivulet not gold but platinum.

The best, if an undesigned, reply to his whole argument, and especially to his last paragraph, is to be found in Mr. John Inglis' most able address, printed on page 368 of your number for October 26th. It is not, however, simple.
W. A. S. B.

November 13th.

## THE THEORY OF THE STEAM ENGINE.

SIR,—Professor Smith's letter in your last issue is of an unfortunate type. I fail to see that he has given me any reason to withdraw any statement I have intentionally made. I find, however, that I have credited myself in your issue of the 2nd instant with the statement that "Clausius bases his exposition of Carnot's theory on the postulate that heat cannot be transferred from a hotter to a colder body without the expenditure of an equivalent in work." The adjectives hotter and colder are, of course, here transposed, as is sufficiently obvious to any reader of ordinary acumen from the context. Professor Smith's letters utterly fail to convey any idea of value to my mind. He is completely in error in asserting that I impute to him that he "undervalues Carnot's work." I have simply asserted that "I have no sympathy with those who undervalue Carnot's work," and here I am assuredly within my right. I note also that he stumbles awkwardly over the significance of the signature appended to a letter from a gentleman writing from Soho. "Ttaw" is simply "Watt" written backwards, whereas Professor Smith will, I have no doubt, have very much amused that versatile gentleman, by supposing him to have "hiccoughed" over a signature intended to represent a letter of the Greek alphabet not uncommonly used to denote absolute temperature. He does not himself, however, scruple to misquote "Ttaw" as well as your humble servant.
HENRY CHERRY.

Putney, S.W., November 9th.

SIR,—At various times engineers have written to THE ENGINEER combating views expressed by physicists and professors, and now at last after years it seems that the truth is going to prevail. On our side we now have Professor Smith and Professor Alexander, and I have good hope that we shall add to the list.

Thermodynamics have been complicated and invested with much mystery by ingenious mathematicians, who have drawn various deductions from more or less imaginary postulates and assumptions. Carnot's theorem, divested of all its enwrappings, simply means this: It is impossible to get any substance to do work in a heat engine without raising the temperature of the substance. After the substance has done work, it will still have a higher temperature than it had to begin with. In order that the substance may be used over and over again, its temperature must be reduced to its pristine temperature. This represents a loss. This loss bears a definite relation to the whole heat communicated to the working substance. It is entirely independent of the nature of the substance. The efficiency depends entirely on the difference between the highest and lowest temperatures encountered in the cycle. These propositions, instead of stating a universal truth, state a truth which has only a limited application, for a reason, which, with your permission, I wish to place before your readers.

In the first place, then, the proposition that the efficiency of a heat engine is independent of the nature of the working substance is untrue, because it takes no cognisance of the internal work done in the substance, which varies with the substance.

Clerk-Maxwell invented for a particular purpose certain intelligent little demons. I shall venture to use these demons to make my meaning clear.

In a cylinder with a piston are collected some thousands of demons; they are fairly quiet. Heat is applied to the cylinder, and they, not wishing to be roasted, try to get out. To do this they push the piston, which they regard as a door, and they exert all their energies in this way, and do all the work in their power on the piston. In another cylinder, I have, however, another lot of demons, who are as quarrelsome as the first were peaceable. When the fire is lighted, instead of devoting all their energies to pushing the door, they begin to fight fiercely with each other. Black eyes, and broken heads, and dislocated tails abound. Their energy is wasted on this strife, and the piston is not pushed with much force. We have here a homely but satisfactory illustration of the effect of internal work. Now, in the steam engine the internal work expended in making the fluid steam is enormous, and never can be utilised, and in like manner various other fluids, liquids, and solids might be named, all of which will give different results on the application of heat, depending on the amount of internal work done.

In order that Carnot's theorem may apply, it is clear that the rise in temperature of the working substance, brought about by the application of heat, must bear a definite relation to the quantity of heat supplied. Temperature admits of being used as a factor of efficiency, only because it is supposed to represent a definite quantity of heat, the proportion of which E available for work is represented by $\frac{T-t}{T} = E$. Temperature is, of course, merely a quality, and not a thing in the sense that heat is a "thing." It is supposed, as I have said, to be a measure of the quantity of the "thing" present. Double the temperature in a given weight of gas, double the "quantity of heat," and so on, but when we come to deal with such fluids as water, ether, petroleum, chloroform, &c., we soon find that temperature does not represent the quantity of the thing heat, and accordingly Carnot's theorem does not apply; and it is by no means certain that a reversible heat engine, such as Carnot devised, represents the maximum work that can be got out of a given quantity of heat, as measured in terms of $\frac{T-t}{T}$. Indeed, I have already shown that a steam engine working within normal limits of temperature may be actually twice as efficient as Carnot's theorem would make it appear to be.

I fear it will be said that I am going over old ground; but I cannot help thinking that some serious improvement in the teaching of thermodynamics is impending, and I would promote the good work by pegging away. So far no one has attempted to say that I have said that which is unsound, and now I have two professors on my side, so that great possibilities open up.

I know very little about gas engines, but I strongly suspect that their efficiency is higher than it would appear to be indicated by the temperature range in them. This is a point on which light might with great advantage be thrown by those who, like Mr. Dugald Clerk, Mr. Dowson, or Mr. Atkinson, have given the subject careful thought. I am credibly informed, indeed, that those engines in which the temperature ranges are least are the most economical. The question is, it seems to me, one of much importance for users of gas engines, and might be thrashed out with advantage. I think a satisfactory theory of the gas engine is wanted just as much as a theory of the steam engine. If I am not misinformed, Professor Smith has devoted recently a great deal of consideration to the subject. Perhaps he will say whether it is or is not true that the economical efficiency of the gas engine, other things being equal, is not much affected by the temperature range.
MAURICE CROSS.

November 12th.

SIR,—The problem of perpetual motion should present no difficulties to Mr. Haig. He evidently does not believe in the maxim *ex nihilo nil fit*. As, however, many thermodynamicians recommend the adoption of 500 lb. pressure, it may be of interest to practical engineers to know the difference between the maximum theoretical efficiency attainable with 150 lb. and 500 lb. boiler pressure calculated on the data and assumptions described in my letter of November 6th. Assuming the feed-water to be raised by the regenerator to 200 deg., the minimum weight of coal per hour in the case of 150 lb. pressure is 1·5 lb. per indicated horse-power. For steam of 500 lb. indicated pressure the temperature is about 470 deg., and $E = \cdot294$, and the theoretical work done by the steam $= 3\cdot1 \times \cdot294$-horse power $= \cdot91$-horse power; at 150 lb. pressure 1 lb. of coal will evaporate 7 lb. of water, and at 500 lb. pressure 6·3 lb. The work done in overcoming back pressure will be equal to $\frac{\cdot05 \times 6\cdot3}{7}$ horse-power $= \cdot045$-horse power, and the maximum attainable indicated horse-power per pound of coal ·865 indicated horse-power, or 1·16 lb. of coal per indicated horse-power per hour. With a pressure of 500 lb. there would have to be several more cylinders to bring the final pressure down to 7 lb. And we have to set against this theoretical gain in indicated efficiency—(1) Greater losses by conduction of heat; (2) diminished boiler efficiency, the rate of conduction of heat from the gases of combustion would be less, and more heat would pass up the chimney; (3) greater machinery friction. Brake horse-power, not indicated horse-power, is the true test of the efficiency of a steam engine. It is to increased boiler efficiency that we must look for increased efficiency in steam installations, not to increased pressures.
WILLIAM DONALDSON.

November 12th.

SIR,—It is taught, and no doubt properly, that for a perfect gas $p v t$ = a constant. If a gas expands without doing work $t$

remains unchanged, but $p$ and $v$ alter, their product remaining constant.

If, now, a gas is heated while expanding and doing no work, $v$ changes at a known rate, and both $p$ and $t$ will be augmented. Will any reader tell me how much? I have failed to find a formula which will apply; indeed, it seems that the problem has been entirely overlooked, and yet it is one of very great importance. Under no other conditions can heat be applied to a gas without doing work. LEX.

Batley, November 12th.

SIR,—In the third line of the last paragraph of my letter to you of 3rd inst., there occurs a misprint in the omission of the word "not" between the words "did" and "write."

ROBERT H. SMITH.

Mason College, Birmingham, November 10th.

### TRACTION ENGINES.

SIR,—I trust your able article championing the extended use of "Steam on Common Roads" will be the means of initiating a powerful combination of traction engine owners and makers, whose object shall be to get the present Highway Acts considerably improved. The fact of the Board of Trade having in hand the subject of light railways makes this an opportune time for taking up the matter in an energetic manner. What is, in my opinion, most necessary to develope or extend the use of traction engines, is for the Government to issue an universal licence—the money paid for such to be used as you suggest—which permits an engine to be used upon any public road in Great Britain, instead of as at present allowing local authorities to issue special licences for engines working in their respective areas or boundaries. This multiplicity of licences almost prohibits a traction engine from hauling for long distances, as every time it enters another borough or county the owner must take out a fresh licence, or is liable to be hauled up before a bench of magistrates, who as a rule have no affection for traction engines.

The above is only one grievance out of a great number, and I trust you will kindly allow your valuable paper to be the medium of exposing others and suggesting remedies. I. H. M.

Leeds, November 8th.

SIR,—As a user of traction engines, I feel that the thanks of all traction engine owners should be given you for the excellent article in your issue of November 2nd. At the same time I would like to point out one or two errors. First, the general impression that it is necessary for a man to walk in front of an engine carrying a red flag. This part of the Road Locomotive Act has been repealed, and it is not now necessary to carry a flag. This error is so general that I have known a case where an engine owner has been compelled to pay an extortionate claim where the judge would not believe this part of the Act had been repealed. Then again, the idea of stopping an engine over ten tons weight would mean preventing heavy haulage, such as large boilers, &c.; why in the interest of the roads should only a ten-ton engine be used, when, say, a thirty-ton load has to travel—surely what will carry the load will carry the engine.

I cannot see why it should be such a very difficult matter to get amendments to the Act, which should allow traction engine hauling to be conducted in the same manner as any other legitimate business, and not to be continually under police supervision. Town Councils do not seem to have much trouble in getting the Local Government Board to sanction most unjust bye-laws, which prevent the free use of "steam on the road."

Steam has revolutionised navigation, manufactures, and passenger traffic overland. There can be no doubt that if steam was only allowed, as your correspondent "I. W. B." says, "fair play and no favour," it would very soon do the same on our highways. Steam traction even under present restrictions is too powerful to be swept out of existence. I think that traction engine owners and makers should not be satisfied with any Act which did not abolish all restrictions as to working hours and mechanical arrangements, so long as weights and width of engine complied with the Act. I do not hesitate in saying that the steel cross bars on driving wheels have done more to retard the use of traction engines in towns than all other reasons put together. It is not an unusual sight to see an engine trying to travel on greasy pavement and utterly incapable of progressing, but sliding first to one side of the road and then to the other, to the danger of passers-by, alarming horses, and stopping the general traffic, so causing a real nuisance. If this can be prevented by using any improved wheel, then it becomes the duty of our lawmakers to legalise such improvement. I would suggest that for heavy traffic a speed of four miles an hour should not be exceeded, which is quite fast enough for heavy haulage. With suitable regulations there would be no necessity for more light railways and objectionable steel rails on the road. Properly-designed traction engines and wagons could be made to meet all requirements for cheap transport over long or short distances. I would propose that no restrictions as to time in which an engine might travel could be obtained by any authority, and that a licence fee of, say, £20 per annum be paid to Government for each engine used for hauling, and £5 per annum for each agricultural engine used only for agricultural purposes, this licence to permit travelling on any road in the kingdom and exonerating its owner from any claim for alleged damage to roads or bridges—the application for this licence to be accompanied by a report from a boiler insurance company, certifying the safe working condition of the boiler.

In Lancashire and Yorkshire the county hours allowed for working are the same, in Cheshire the hours are fixed for the whole year, you may travel in winter up to 7 p.m., then cross a bridge into Lancashire, and find you are two hours after stopping time in that county. Then in many of the county boroughs the sanction of the Local Government Board has been obtained to stop engines travelling in the daytime, as though workshops, factories, railways, &c., were kept open all night receiving and delivering goods, under the mistaken idea that horses and drivers who are alarmed at traction engines in the daytime are not at night. I think the Local Government Board before sanctioning "bye-laws" such as one County Borough has in force, viz., that under no circumstances, no matter how heavy a load may be, will two engines be allowed to work together—I know that one engine being overloaded will do more damage to streets than two engines will do working lightly—should submit them to some practical committee, who would also consider the men whose working hours are doubled by a stoppage of eight hours a day. This is hardly "up to date," when shorter working hours are being adopted in all trades and Government works.

It is pleasant to read in your last issue a letter from a "County Surveyor," saying that good roads will stand traction engine traffic, but surely he must be trying to amuse your readers when he speaks of stopping engines when fox-hunters are about. I am sorry the awnings on engines frighten Gloucestershire horses, as they do not in other counties, and the difficulty about the oil can easily be got over by adding to it some sweet-smelling perfume. I am glad that he can see that a suitable engine with proper driving wheels will cause the opposition to die out. TRACTION.

SIR,—Will you allow me a small space to reply to the letter of Mr. Robert Phillips, which appeared in your issue of the 9th inst. Mr. Phillips admits that the wear of the road in fair average repair, due to traction engine traffic, is nominal; in fact, as stated in your leading article a few weeks since, there is less damage done in hauling a given weight than would be caused by horse traffic, provided the engines are not excessively loaded; so that the objection to traction engines upon these grounds cannot have much foundation.

The remainder of his letter abounds in contradictions. Whilst professing to sympathise with the unfortunate agriculturist, he proposes an additional tax in the shape of a licence upon thrashing engines, the greater part of which must ultimately be paid by farmers hiring them, in the shape of an increased rate of hire. He also proposes prohibiting their use at all upon certain roads, and as a county surveyor is an autocrat upon all questions affecting highway bye-laws, the effect of this would probably be that many farmers would be unable to employ a traction engine for thrashing purposes at all.

I do not agree with the reason he gives for the difference shown by horses between meeting a steam roller and an ordinary traction engine. The horse is an intelligent animal, but I must confess I can hardly think he has discrimination enough to distinguish between a clean engine and a dirty one. The cheap oils so much used now are principally mineral, and are almost devoid of smell, much more so than the more expensive animal oils when heated by the boiler. The true reason is that the motion of a steam roller is not visible, and if the Legislature were to insist upon a circular plate to cover the spokes of the fly-wheel, and side plates mounted upon the barrel of the boiler to hide the motion of traction engines, I do not think owners would object to the small cost of these alterations.

As to Mr. Phillips' statement that he would not let traction engines run when fox-hunters are about, would it not be better to stop all trains in the district instead, as they are infinitely more dangerous to hounds than all the traction engines in the country would be? I should recommend him to study the fable of the boys and the frogs. The case against traction engines lies in a nutshell. Gentlemen often drive out with raw or imperfectly broken horses, and these naturally object to pass an engine. I have driven an engine many hundreds of miles upon the road, and my experience is that in the great majority of cases the driver is more afraid to pass than the horse is.

Traction engine owners simply ask the privilege accorded to other traders of carrying on their business without the persecution which has been dealt out to them in some counties, and if the law at present will enable the highway authorities to ruin any engine owner, it is only in accordance with English sense of justice that such alterations should be made in the Locomotive Acts as will prevent this.

AN AGRICULTURAL ENGINE OWNER.

Norwich, November 12th.

### THE INVENTOR OF THE BLOCK SYSTEM.

SIR,—I think the following extract from Mr. Edwin Clark's report of March, 1854, to Mr. Huish, will show that although the permissive block system was eventually adopted as sufficient for the then traffic on the North-Western, still my uncle described an absolute block system very much the same as that at present in use. LYONEL CLARK.

November 13th.

[Extract from Letter to Captain Huish, March, 1854.]

"The following would be the details of such a system:—The line should be divided into convenient sections the length of each section being from one mile to five miles, according to the traffic. In most cases the signal stations would be at the existing railway stations, and under the control of the station-master. Each station should be provided with a semaphore, and with two telegraphic instruments, one of which is devoted exclusively to the section of line on the up side of the station, and the other to the section of line on the down side. They are exactly similar in construction; we will therefore confine our attention to one of them. It has two dials and needles, with corresponding handles, and upon each dial are engraved the words 'Line Blocked' or 'Line Clear.' Both of these dials are in connection with an instrument in the next up station, which we will call A, our own station being termed B, and the next down station C. One of the dials indicates to the signalmen at A the condition of the line between him and B. If the line is clear, B keeps the needle permanently blocked over to the right, and if at this time a train approaches A, he does not hesitate to let it pass on to the next section towards B. Immediately, however, that he has done so, he gains the attention of B by vibrating the needle, and indicates that a train has passed on to his section—distinguishing it if necessary by an appropriate signal, as an express train, or goods, or ballast train. On receiving this B immediately changes his needle over to the left or 'Line Blocked,' thus indicating to A that his signals have been correctly understood. When the train approaches B he again reverses his needle to the right, informing A that the line is clear; he at the same time perceives, by the indication of the needle belonging to C, that the next succeeding portion of the line is clear, and allows the train to proceed onwards without interruption, but at the same time calls C, and having signalled the progress of the train towards him, does not rest till he perceives that C has changed his needle over to the left of 'Line Blocked.' In like manner a train approaching on the up line of rails has its way prepared before it, and the line closed behind it until it has reached the next station."

SIR,—The Norwich and Yarmouth single line of railway was worked on Mr. Cooke's—Cooke and Wheatstone—system of absolute block before 1845. It was on that line, and in that year, I commenced my telegraph life. By his method one could see at any station in what section the train was running. The plan was abandoned because of its great cost, except for tunnels. In 1846 Claycross tunnel on the Midland, among others, was signalled on Cooke's system. No second train was allowed to enter till the tunnel was clear.

Mr. Little is perfectly correct in his description of Edwin Clark's method. Though Cooke invented the telegraphic block, it is to Clark we owe the adoption of a general system of train signalling. His permissive method introduced, as it were, the thin end of the wedge by merely warning the drivers; had he proposed to stop the trains altogether, he would have so greatly alarmed the railway world as to lose all chance of success. R. S. CULLEY.

Weston-super-Mare, November 12th.

SIR,—I have read with much surprise the letter of Mr. C. J. Little—page 405—contradicting the statements relating to the late Mr. Edwin Clark, which appeared in your article—page 367. In 1853 Mr. Clark introduced on the London and North-Western Railway "block" instruments, having three positions "line clear," "train on line," and "line blocked." The absolute block system as used on the North-Western and other lines to-day, *is* the very same three-position system as introduced by Mr. Clark, and one of the original instruments used in 1854 at Crick station is still preserved at South Kensington Museum. It is quite absurd for Mr. Little to claim the invention in 1865, for I can myself well remember the absolute block long before that date, and it has been in use for certainly forty-one years on the London and North-Western Railway. CLEMENT E. STRETTON.

Saxe-Coburg House, Leicester, November 9th.

[We can publish no more letters on this subject.—ED. E.]

### LOCOMOTIVES, TRAINS, AND BRAKES.

SIR,—The letter from Mr. Edward J. M. Davies, in your issue of November 9th, is very interesting indeed, and as it touches on railway brakes, which are the most important preventatives of loss of life and property, perhaps you will allow me to point out that he has made a fundamental error in his calculations as to the distance the train of the Northallerton smash would have run—before being stopped by the brakes—at a speed of sixty miles an hour—assuming the mode of applying the brakes to have been theoretically correct, *i.e.*, just short of skidding, dry rails, &c.

He starts by assuming that every wheel of the coaches on this train was braked, whereas the East Coast Joint Stock being six-wheeled, only four out of six wheels can be braked, so that only two-thirds of the thirteen six-wheelers were braked, or only 112$\frac{2}{3}$ tons out of 169 tons. I take his weight for the carriages, but the East Coast Joint Stock weighs 14 tons.

The Pullman being on bogies was all braked, so 25 tons was correct for it, and taking his figure of 81 tons of braked weight on the engines, we have:—Thirteen six-wheelers = 112$\frac{2}{3}$ tons; one Pullman = 25 tons; two engines = 81 tons; total, 218$\frac{2}{3}$ tons; and the weight of the train being 356 tons, we have only 218$\frac{2}{3}$ tons braked out of 356 tons, against Mr. Davies' 275 tons; or 61·26 per cent. against his 77·24. In these days of high speeds and crowded main lines, it would seem imperative that all coaches should be built on bogies—either eight-wheelers or twelve-wheelers, certainly the latter for express trains—in order that every wheel may be braked, and stops made in the shortest possible time in case of danger. Mr. Davies gives only 50 per cent. of the engines and tenders as braked, but surely this is wrong, as the drivers and all the tender wheels are braked, leaving only the bogie or leading wheel unbraked. I should think this meant 80 per cent. of engine and tender braked.

It would be of great interest if Mr. Davies would take the above corrected percentage of braked weight on the Northallerton train and show (1) how far it would have travelled after the full application at 60 miles an hour, (2) how far if the coaches had been all bogies and so braked on every wheel, and (3) how far if it had been braked on all the wheels, including the leading wheel of the one engine and the bogie wheels of the other, *i.e.*, 100 per cent. braked.

I think Mr. Davies lays too much stress on a possible jar which might be caused by having the engine wheels all braked, as I never heard of this before, and they certainly do not suffer from such in America, where they are, for reasons of safety, braking the bogie wheels of their largest locomotives; and even if one were pitched on to the person opposite it would not matter so long as a collision was averted or lessened by a quick and fully applied brake force on every wheel.

In my letter which you printed last week the compositor has altered my "G.S.W.R." into "G.S. and W.R." twice over; it is the Glasgow and South-Western, which is, like the Caledonian, building nothing but eight-wheel bogie coaches.

I hope "Scrutator" will extract from Mr. Bowles some light on the mysterious Mr. Macdonell locomotive with water pick-up.

NORMAN D. MACDONALD.

November 12th.

SIR,—Referring to my letter on the above in your last week's issue, I notice that through inadvertence the quantities 11·6 and 15—as values of ($x$)—in the latter part of the letter, was stated as tons; they should have been per cent. Although it does not affect the subsequent working, I thought it best to call attention to this. EDWARD J. M. DAVIES.

24, Harrington-square, London, N.W.,
November 13th.

### THE UTILISATION AND PURIFICATION OF SEWAGE.

SIR,—Your current article on the above subject represents the view I trust that Parliament will take in considering the proposed Rivers Pollution Bill, which the president of the recent Sanitary Congress informs us will probably be passed at an early date, and that such legislation is required is abundantly proved by the facts given in THE ENGINEER.

To one or two of the chief facts permit a brief reference and endeavour to show how the difficulties of our present sewage procedure originate and, I believe, may be overcome, basing the belief partly on actual experience in support of the central fact connected with sewage and the soil, at the same time taking it for granted that under "normal conditions" the bacteriological system, which in nature operates through sewage in the air, the water, and soil, works in ordered sequence and design, and that any reversal or retardation of the normal course modifies the function and effect in a like degree. On this basis the cause of failure in sewage procedure become apparent, whilst the remedy required is open to demonstration by simple means, taking the normal function we know to operate on organic matter in water, sewage, and soil as affording the proof required.

Taking the definition of function from Mr. Warrington, F.R.S., we have two distinct orders of bacteria operating on soil—the one fixes the ammonia and lives on bicarbonates and converts them to nitrites, the other oxidises the nitrites to nitrates, the food of plants. Now, Sir, if sewage is taken—previous to putrefactive ferment setting in—and is thoroughly aerified and sufficient time allowed for bacteriological settlement, analysis of the effluent will exhibit almost equal proportions of bicarbonates and nitrites as organic matter or constituents wholly in accord with the function described, and I suggest the fact exhibits a sequence in function, in water, and soil. On the other hand, sewage either during or after putrefactive ferment subjected to the process named exhibits totally different conditions. Therefore, I suggest the facts named—which are open to demonstration—go far to prove that by adopting a sewage procedure of preventing putrefactive ferment in sewage—sewers—which is wholly feasible, we may remove the chief difficulty of purifying effluent sewage on the land for unlimited periods, whilst ensuring its utilisation for plant life to the maximum degree, while as regards the more solid matter the bulk and its cost would be reduced at least two-thirds compared with either a chemical or other method of production. But, Sir, there is another aspect of sewage which is, I suggest, of infinitely greater moment to populations than any question of utilising or purifying sewage, that is the ever-increasing organic pollution of the air. Cause and remedy in this case I believe to be involved in the cause and remedy already described; that is to say, by insuring normal conditions in sewers—which is possible only by continuous destruction of the volatile elements of sewage—we at the same time ensure a normal bacteriological function in the air just as much as in water and soil.

In conclusion, I believe the essential facts involved are open to demonstration in the widest sense, and as THE ENGINEER points out, both European nations and America also have already deemed the mere purification of sewage a question of sufficient importance for State experiment, and I beg to suggest our own Government might well endeavour to solve the problems involved in sewage pollution of the atmosphere, the water, and soil.

Sheffield, November 12th. HILL HARTLAND.

SIR,—Your leader on "Sewage Purification" has attracted my attention, and in reply to your criticisms as to chemical purification, I have pleasure in handing you herewith the chemical report of Mr. L. Vuaflart, and the microbiological report of Dr. Billet, relating to experiments they made at the Exhibition of Boulogne with my installation for the treatment of sewage by polarite.

As you will see, the experiments were carried out with the greatest care, and the results prove that polarite is a wonderful purifying agent; if in certain installations in England polarite only clarifies, but does not purify, as you say, the blame lies with the designer of the works or the management, and not with the material.

On page 10 of Mr. Vuaflart's report, he concludes as follows:—(1) That the effluent was at all times limpid and odourless; (2) that the effluent remained without alteration for at least fifteen days; (3) that in addition to the organic matter in suspension, from 84 to 88 per cent. of that in solution was removed; while Dr. Billet concludes thus:—(1) Crude sewage, 5,250,000 microbes per cent. cube; (2) crude sewage, after precipitation by ferozone, 812,500 microbes per cent. cube; (3) crude sewage, after filtered through polarite, 42,000 microbes per cent. cube. That is to say, a little more than 99 per cent. of the microbes were removed, or 992 per 1000.

If, then, this result can be obtained in Boulogne, it can be obtained in England. Polarite will do its work in any country if properly applied.

I hope that these reports will interest you.

ANDREW HOWATSON.

165, Avenue du Roule, Neuilly-sur-Seine, Paris,
November 13th.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

G. A. H.—*The power required to propel a ship varies roughly as the cube of the speed, not as the square.*

W. D.—*You seem to have confounded pressure with work. There is no such difference as you presuppose between the efficiencies of boilers of diverse construction.*

### METALLIC PACKING.

(*To the Editor of The Engineer.*)

Sir,—Permit us to say, in reply to the letter of "Gland" *re* piston-rod packing in your last issue, the metallic packing we make being of phosphor bronze has no tendency whatever to corrode the rods, and appears to be what he alludes to. E. E. Baly.

Farringdon Works, Shoe-lane, London,
November 13th.

(*To the Editor of The Engineer.*)

Sir,—In reply to "Gland's" inquiry in last week's Engineer *re* metallic packing, if it has a tendency to corrode the rod, we would say that there are a variety of so-called metallic packings in the market, some in combination with a fibrous material, others in rings and springs to keep it in contact with the rod, so that unless "Gland" can say which packing he has in his mind, no satisfactory reply can be given. Haughton & Co.

110, Cannon-street, London, E.C.
November 14th.

### GRANITE, STONE, AND MARBLE QUARRIES.

(*To the Editor of The Engineer.*)

Sir,—In reply to a letter of "P. T. J., Burnley," I think there is no work published on the locality of any stone and marble quarries throughout the world, but there is a handbook on "Marble and Marble Workers," by Arthur Lee, published by Crosby Lockwood and Company, which gives full particulars relating to the principal marble quarries in the world. J. L. Williams.

Bristol, November 13th.

### BURY, CURTIS AND KENNEDY.

(*To the Editor of The Engineer.*)

Sir,—I am very desirous of ascertaining when the once well-known firm of Bury, Curtis and Kennedy, locomotive builders, of Liverpool, ceased to carry on business I have traced engines built by them down to 1849, but believe they built later than that. If any reader could inform me on the point through The Engineer I should be very greatly obliged. W. B. P.

Boscombe, Bournemouth,
November 12th.

## SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)* .. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* .. .. | £0 18s. 0d. |
| *Yearly* .. .. | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* .. .. | £1 0s. 8d. |
| *Yearly* .. .. | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

## ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

Newcastle-upon-Tyne Association of Students of the Institution of Civil Engineers.—Wednesday, November 21st, at the Durham College of Science, at 8 p.m. Paper: "The Irlam Section of the Manchester Ship Canal," by W. O. E. Meade-King, M. Inst. C.E.

The Institution of Junior Engineers.—Saturday, November 17th and 24th, at 2.30 and 3.30 p.m. Visit to the *Globe* newspaper printing-office and Linotype Machine Installation, &c., 367, Strand.

The Institution of Electrical Engineers.—Thursday, November 22nd, at 8 p.m. Paper: "Electrical Steep Grade Traction in Europe," by Charles S. du Riche Preller, M.A., Ph.D., member; "Notes on Electric Tramways in the United States and Canada," by H. D. Wilkinson, member; "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by R. W. Blackwell, foreign member, and Philip Dawson, associate. Discussion.

North of England Institute of Mining and Mechanical Engineers.—Saturday, November 24th, at the Wood Memorial Hall, Newcastle-on-Tyne, at 2 p.m. General meeting.

Royal Meteorological Society.—Wednesday, November 21st, at 7.30 p.m. Papers: "Methods of Determining the Influence of Springs on the Temperature of a River, as illustrated by the Thames and its Tributaries," by H. B. Guppy, M.B.; "Some Effects of the Gale in the Highlands of Scotland on November 17th and 18th, 1893," by Eric S. Bruce, M.A., F.R. Met. Soc.; "History of a Waterspout," by Alfred B. Wollaston.

North-east Coast Institution of Engineers and Shipbuilders.—Saturday November 17th, at 6 p.m. Paper: "A Brief Outline of the Theory of the Rolling of Ships," by Mr. Andrew Young.

Society of Arts.—Wednesday, November 21st, at 8 p.m. First ordinary meeting. Opening address of Major-General Sir John Donnelly, K.C.B., Chairman of the Council.

The Institution of Mining and Metallurgy, London.—Wednesday, November 21st, in the Lecture Theatre of the Geological Museum, Jermyn-street, S.W., at 8 p.m. Paper: "The Practical Operation of the Cyanide Process on the Witwatersrand—Transvaal—Goldfield," by Mr. Manuel Eissler, member.

# THE ENGINEER.

*NOVEMBER* 16, 1894.

## LIGHT RAILWAYS FOR FARMERS.

History repeats itself. The "battle of the gauges," fought a quarter of a century since, seems in a fair way to be repeated. It is but yesterday, so to speak, that the Board of Trade issued a circular on which we have already commented, and the columns of the daily press are full of articles, correspondence, calculations, arguments, concerning light railways. We are told what they should be and what they should not be; how much they ought to cost and ought not to cost. The advice given would be bewildering if anyone paid the least attention to it. The latest development of the controversy is the use of light railways for the purpose of pulling down the House of Lords. They are to afford admirable political capital for the next Parliamentary campaign. They are to keep people in the country instead of glutting the towns. Engineers and others possessing common sense and some knowledge of railways are disposed to put their hands to their ears and fly from the nonsensical turmoil; but flight in this fashion is not consistent with the discharge of duty. It is well that someone should speak with authority and recall the world to its senses. It is proper that someone should insist on the truth that light railways are not heaven-sent gifts, competent to perform impossibilities, but merely more or less inefficient aids to locomotion; things useful enough in their way judiciously employed, yet possessing unfortunate powers of wasting money unless their proper position in the internal economies of a country is fully appreciated. The correspondence hitherto published in this connection seems to be the work mainly, if not altogether, of individuals who have no practical knowledge of railway management. They appear in the light of more or less amiable enthusiasts when they are not utilising the light railway as political capital, or as a promising subject for company-mongering in the future. The latest idea is that parish councils should take land compulsorily, reduce the sum to be paid as compensation on the plea of betterment, and then grant a concession to a syndicate. The scheme seems worthy of those who started the South Sea Bubble. The unlimited opportunities afforded for peculation commend it to unprincipled City men. The widow and the orphan will be supplied once again with the chance of accomplishing speedy starvation. Is it not time that engineers should lift up their voices, and warn and expostulate?

There are numerous situations in which a cheap railway would do a great deal of good, but, unfortunately, the situations in which a cheap railway can be constructed are by no means plentiful. The first essential to cheapness is an easy country. The cost of the permanent way is quite a small item as compared with that of earthworks, bridges, and such like. The favourite idea with the amateur is that embankments and cuttings are unnecessary. Why not let the line go up hill and down dale? If it is urged that this convenient method of construction cannot be employed in the case of a normal railway, we are at once met with the reply, "Oh! but you see this is only a light railway." Then we have the Festiniog Railway produced in evidence of what can be done with a 2ft. gauge line. This little railway has supplied a most mischievous precedent for amateur railway makers. They steadily ignore the circumstance that the whole of the heavy traffic in slates is carried down hill; that the engines have only to haul empty wagons back from Port Madoc to Festiniog; that slates are better suited for conveyance on a narrow gauge road than any other commodity, and that the passenger service consists almost exclusively of tourists in the summer season. The Festiniog line is in no sense or way a precedent. All this has been thrashed out years and years ago, and yet we find the Festiniog line dragged once more into publicity within the last week, and there is good reason to believe that another combat will be fought over it, its merits and demerits. The truth is, that a light railway can no more comfortably traverse hill and dale than a heavy one. Both can be made to do it, but at a stiff price. Thus, to cite a very well-known case, we may take that portion of the Midland Railway which traverses Derbyshire. A light railway could have been laid through the country, say, from Ambergate to Buxton. It would have cost less per mile, but it would have been comparatively inefficient, and as a matter of fact, the reduction in the cost would have been very small. It has been proved over and over again in every country under the sun in which a railway system exists, that the cost of a road is very little affected by the gauge. It is quite true, all the same, that there are numbers of light railways in existence which have cost very much less per mile than normal lines. But this was scarcely, if at all, due to the reduction of gauge. It is obviously wholly a consequence of the inferior character of the road. The inclines are steeper, the ballasting is worse, the curves are sharper, and so on. The difference is kindred in character to that between the price of a good horse and of a small pony or donkey; and the difference would have been very much the same whether the gauge was 4ft. 8½in., or 3ft., or 2ft. 6in. About this there is really no room for dispute. Every railway contractor in the kingdom, every civil engineer versed in railway work, knows all about it. There is no longer any question. There is nothing to discuss. There is a saving due to the narrowness of the gauge, but it is scarcely worth having. Reduced to its simplest aspect, the light railway is cheap because it is inferior in every respect to the normal railway. It is not, as some folks would have the world believe, just as good, but cheaper because it carries only four persons on a seat instead of five. The gauge of a line is the least important factor in determining its cost.

But we are very far from saying that because a line is cheap and inferior it must be useless. On the contrary, a light railway may do excellent service. So patent and prominent, indeed, is this truth, that it is apt to overshadow others quite as important, but much less obtrusive. Let us ask ourselves what a railway, cheap or dear, can do? The answer is, that it can carry goods and passengers from place to place. For the moment it is unnecessary to consider the extension of light railways into the mineral districts. "Light railways for the agricultural districts" is the watchword just now. Let us ask ourselves, Do the agriculturists want them, and how will they help them? A very considerable authority on agricultural subjects, a man who not only has the agricultural interest at heart, but one who possesses a special knowledge of the subject, and is a member of the recent Royal Commission on Agricultural Depression, has already in the pages of a contemporary pointed out that farmers are by no means likely to regard the cheap railway as an unmixed blessing; and he gives numerous reasons why they should not regard them with favour. In various parts of the country, again, farmers have come forward to oppose such railways. The time has long since passed away when such protests could be put down to prejudice. The modern English farmer understands what is and is not good for him better than anyone else. The relations of the farmer and the light railway have been discussed over and over again. It has been shown that an isolated cheap railway here and there can be of no great use; that in most agricultural districts of any importance there is already an excellent railway service; that the cartage seldom much exceeds seven miles to a station; that the cheap railway could only reduce this distance in a few instances; that, even if the contrary were the case, horses would still have to be used, carts would have to be loaded and unloaded, and that the necessary saving to the farmer would be very small, if any; that the cost of haulage on a cheap railway must be greater than on a normal line, ton for ton; and that if the cheap line was used as a feeder to a main line, transhipment must take place. This latter point is one of the utmost importance. Break of gauge has ruined the narrow-gauge system everywhere, and need not be considered. But the proposal to obviate transhipment by making cheap railways to the normal gauge is now being advocated by men who obviously know nothing of the conduct of railway traffic. In the first place, if the normal gauge is retained, the slight saving in earth works secured by the adoption of the narrow gauge is at once sacrificed, while nothing is obtained in return so far as transhipment is concerned. The rolling stock of a normal road could not be used on a light railway, and the wagons suitable to the latter would be cracked up like egg shells if mixed up with those of a normal goods train. All this is old information to railway men, of course, but it is none the less necessary to reproduce it here. Many years ago we suggested in these pages the only system of applying steam to the service of the agriculturist that appears likely to meet his wants. Briefly, this scheme consisted in taking to the farmyard a wagon so constructed that it would run equally well on a light railway or on a farm road. These wagons being loaded could be collected by a traction engine, also fitted to run on either road or rail, and a train of these being made up it could be hauled along the light railway to the nearest railway station. We need not go into detail; nor need we consider whether the system would pay or not. Its merit lies in the fact that the farmer would be saved the entire cost of hauling. It is in a modified form the system of collecting now employed by many of our great railway companies.

It will perhaps be urged that we have written in condemnation of light railways and of the movement in favour of their construction. We have in a limited sense. We do not believe that light railways can confer any universal blessings on farmers or allotment-holders. But we are, on the other hand, strongly in favour of the judicious construction of cheap railways to unite considerable villages and small towns, now some miles from a railway station, with one. There is, in a word, a sphere for cheap lines in this country, and a much larger sphere in Ireland and in many of our foreign possessions. As an example of what a cheap railway may be, we would, in conclusion, direct the attention of our readers to a proposal for a railway of the kind in Barbadoes, which will be found on another page.

### UTILISATION OF THE NILE.

After all it seems that a compromise is to be effected between the engineers and archæologists on the vexed subject of Philæ. The temples are not to be drowned or removed, and yet the Assouan dam at the head of the first cataract is to be built. The daily papers of last week announced "that the reservoir at Assouan is to be constructed at a lower level than was originally proposed, and the Philæ temples are not to be submerged." Our readers will remember the hot controversy that for some little while raged over Mr. Willcocks's advocacy of a high level reservoir at this site; and his proposal that the temples should be removed piecemeal and reconstructed on an adjoining island, where they would stand well above the level of the highest floods. But nothing short of an entire abandonment of the scheme seemed to satisfy the minds of a certain section of antiquarians, who held that any interference with the crumbling monuments of past generations would be an act of unpardonable vandalism, and therefore on no account to be permitted. Neither did the proposal of Sir Benjamin Baker, the English member of the Technical Commission, who sought to overcome the difficulty by raising the buildings bodily, *in situ*, seem to meet with acceptance.

Under the pressure put upon it, the Egyptian Government seems to have been obliged to give way, but being desirous to retain the best and most economical site for a Nile reservoir, have called on their Public Works to modify the plans in such a way that the wants of Egypt, in the shape of an increased and improved water supply, are in some measure to be provided for, while her interesting relics are to be left untouched by the desecrating hands of the engineers. But we believe that this so-called compromise means in reality a complete renunciation of the proper scope of the project; for we do not read it that a site for the dam farther down the river—that is, at a lower bed-level—has been discovered, and therefore its "construction at a lower level" will mean reduced storage, and consequently a diminished supply for the agriculturists at an increased relative cost, whose interests must therefore suffer, while the State is saddled with a less remunerative scheme.

Although such are our suspicions with regard to this compromise, yet, till the new scheme is made the property of the public—that is, we suppose, after Mr. Willcocks's consultation with Sir Benjamin Baker—we cannot say how far it will affect the whole question. Important interests are at stake in the effective utilisation of the Nile, and an early solution of the problem is highly desirable in the interests of England as the responsible nation, while it is of paramount importance to the Egyptians, who are threatened at closely recurring intervals with a "low Nile" and its deplorable and ruinous consequences.

One hopeful indication of healthy action in the interests of the agricultural class is the encouraging promise of the Egyptian Minister of Finance that funds will be provided for the commencement of the work next year; so that if all goes well, the dam ought to be in progress at the close of next inundation. We confess, however, to an amount of scepticism in this matter, for referring to the plan of Philæ, published in our issue of the 2nd of March last, it appears that a reservoir whose reduced level is 105 00 will swamp the island of Philæ and its temples. At the same time we learn from Mr. Willcocks's report—page 22 of "Perennial Irrigation and Flood Protection for Egypt"—that his design at this level will hold up only 928 millions of cubic metres of water, and as the wants of Lower Egypt are estimated to be at least 1500 millions of cubic metres, we see that unless the temples are swamped the needs of even Lower Egypt cannot be fully provided for. In our opinion, if we are correct in our inferences, the whole question must be reopened, and with it, we have no doubt, will be brought well to the front that of the Wady Rayan scheme, the enthusiastic advocate of which has addressed us the letter which we published some time back, and on which we may have some remarks to make on a future occasion.

### MINE EXPLOSION RELIEF FUNDS.

The recent controversy over the distribution of the funds raised for the relief of the women and children bereaved by the Albion Colliery explosion involves questions of abiding interest in other mining districts than South Wales. It recalls to mind the fact that similar difficulties, not to say squabbles, have occurred times without number, and all over the kingdom, whenever an exceptional mining disaster has caused an extraordinary outflow of public charity. It is a sharp reminder that despite the strenuous efforts of excellent men, extending over thirty years or more, it has not yet been found possible to establish a Relief Fund which can accurately be said to rest on a permanent basis. Such a fund, it is sometimes forgotten, ought to serve two purposes. It has to provide not only for the sufferers by the great catastrophes which arouse the horror and the compassion of the country. It must make provision also for the victims of the almost daily casualties and fatalities which seem to be inseparable from mining enterprise, and which maintain a steady average of about 1000 cases per annum. The general public only hear of explosions like those of the Hartley, the Oaks, or the more recent but equally deadly calamity at the Albion pit. But the managers of the Relief Funds are subject to a constant demand for relief from the survivors of the individual sufferers from "falls of roof," small explosions, and other like perils which environ the miners' life. The ideal fund, and that alone which could be called permanent, would need to be constituted on the same actuarial calculations as a sound insurance society, with a scale of contributions sufficient to meet all conceivable risks. To mention that fact, however, is at once to suggest the difficulty which has been experienced in most former attempts to solve the problem. If the Relief Fund is formed on the scientific lines of an insurance society, the miners' subscriptions are raised to a rate which they say they cannot afford to pay; they would prefer, as thousands of them indeed prefer now, to take the risk; and the very means designed to ensure thrift would lead to a greater degree of improvidence than prevails at present.

The case of the South Wales and Monmouthshire Provident Fund, in its relation to the Albion Colliery disaster, may be taken as an illustration both of the strength and weakness of these organisations. It is essentially a friendly society as distinct from an insurance society, and for every 1s. per month paid by the collier the employer adds 3d., or 25 per cent., the money being collected at the colliery office, but the management is left in the hands of a committee elected by the men. From the balance-sheet of 1893 it appears that in its short existence of about fifteen years it has amassed a capital of £144,614, and in that year had an income of £60,572, and made disbursements of £44,636. Members' contributions amounted to £42,693, the employers' percentage to £10,383, and interest on investments to £4000. There were then on the books 617 widows, and 1103 children who received £15,223, and there were 12,000 of the "accident" class which absorbed the still larger sum of £21,558. This is not at first sight a bad record for a local society of comparatively recent growth. It might, undoubtedly, have appeared still more creditable if a larger proportion of the miners of South Wales and Monmouthshire had made themselves contributors to the fund. But there came the Albion explosion. Nearly all the men employed in the mine were subscribers. There were 135 women and 350 children to be provided for at the stipulated rate of 5s. per week for each widow, and 2s. 6d. per week for each child. There was a nominal surplus on the accounts of 1893; but £14,311 of that had been added to the invested reserve. What, under these circumstances, were the managers of the Provident Fund to do? They were morally bound to the women and children whose lost bread-winners had been for years subscribing members. They could not meet that obligation without drawing on capital and weakening the capacity of the Fund to meet other obligations. It was frankly admitted that the society, to which the mining population looked for aid in just such a crisis as this, was not in a financial position to meet the strain upon it. But close at hand, and practically as yet untouched, was a sum of over £30,000, the result of the Mansion House collection and various public subscriptions for the benefit of the destitute Albion families. The Provident Fund said it could not do without that godsend; it made claim to it; and ultimately it secured it to reinforce its own coffers. There was naturally a loud outburst of indignation in the coal valleys, and particularly among the women most affected. It was called an act of robbery, a shameful example of "grab."

It is unnecessary now to tell of the local strife, or repeat the arguments for and against the annexation of the public donation. Something like a compromise was at last effected, which, if it does not give the Albion women and children all it was claimed that the public intended for them, at least secures them an increase of their weekly doles—the 5s. becoming 7s., and the grant per child a trifle higher, according to the number of the family. But this, though it puts an end to a pitiful scramble, cannot be regarded as a settlement of the whole question. It leaves the proposition still arguable, that all the Relief Funds which claim to be permanent are shaken to their financial foundations every time a sudden and severe demand is made upon their resources, and most people will be disposed to admit that this is a highly unsatisfactory state of affairs.

### THE CYANIDE CASE.

The judgment in this case, which was heard at the end of July last, was reserved at the conclusion of the hearing, and was not delivered until Thursday, November 8th. Mr. Justice Romer's decision was in favour of the defendants, on grounds that will be dealt with in due course. The history of the case and the contentions of the parties to the suit can be succinctly stated to remedy such lapses of memory on the part of the technical reader as are inevitable after a matter has been in abeyance for more than three months.

The action was brought by the Cassel Gold Extracting Company against the Cyanide Gold Recovery Syndicate, for infringement of the former's patent. The patent is that originally granted to Messrs. MacArthur and Forrest, and is for the extraction of gold from its ores by the use of potassium cyanide. The specific infringement complained of was the employment of a process devised by Mr. Pielsticker, an experimental plant for this process having been set up by the defendants. The MacArthur-Forrest patent claims the use of potassium cyanide *per se*, whereas the Pielsticker method involves the passage of an electric current through a cyanide solution, both to aid the solution of the gold and to cause its deposition and recovery. The case at first turned largely on the question whether the extraction of gold from its ores—or from tailings—by means of potassium cyanide, was novel at the date of the plaintiff's patent. It was admitted on both sides that the solvent action of potassium cyanide upon gold was known many years prior to the patent; but it was contended by the plaintiffs that this knowledge had never previously been applied in a practical and workable form to the recovery of gold from its ores. Certain earlier patents were unearthed which had prescribed the use of potassium cyanide, but never alone and unaided either by other substances or by the application of an external force such as a current of electricity. These patents had, moreover, failed in practice. It was also admitted that potassium cyanide as used in the Pielsticker process was the main cause of obtaining the gold in a soluble form; but an experiment put forward by the defendants went to show that a somewhat larger solvent action was secured by the simultaneous passage of a current of electricity. Cross examination, however, revealed the fact that the conditions in the two trials—viz., that with and that without a current—had not been strictly identical, so that the difference observed in the result may have arisen from some other cause. With admirable common sense, Mr. Justice Romer suggested that a further comparative trial, preserving identity of condition, should be made, the Pielsticker apparatus being used first with and then without a current; and approved the employment of an expert independent of both parties to carry out the trials. It is greatly to be regretted that this crucial experiment was not performed. The evidence had been, on the showing of the Court, eminently unsatisfactory up to this point, and a decisive settlement would have been valuable for larger reasons than those concerned in the winning or losing of this particular action. When the suggestion of a comparative experiment was mooted, it was decided to complete the hearing of the evidence already available and then to arrange for the test in question, if both plaintiff and defendant would agree thereto. As the case progressed, the electrical aspect of the matter receded rapidly, and the defendants, with an excellent appreciation of the situation, decided to take their stand on the original evidence, and not to agree to the introduction of a fresh element of possible uncertainty. The event justified this course, for when judgment was given the merit of the electrical part of the Pielsticker process was left undebated, and the action was dismissed with costs against the plaintiffs, save on one particular count, in which the Court considered that the plaintiffs had been put to needless expense by the defendants. The ground on which Mr. Justice Romer based his decision was that no invention was required to discover that gold could be extracted in a practicable manner by the action of potassium cyanide upon the finely divided ore, and that the publication of previous patents embodying this principle had taken place at a date earlier than that of the patent in dispute.

As matters stand now, therefore, the use of potassium cyanide for extracting gold is open to everyone. Valid patents for particular methods of use must rest either on a special mode of applying the solvent or on some process of recovering the gold from the cyanide solution. That this is good law no impartial person who appreciates the value of Mr. Justice Romer's decisions will be disposed to question, but we doubt whether those having a technical knowledge of gold extraction, and being at the same time wholly unbiassed, will be equally unanimous as to the want of originality of the invention of Messrs. MacArthur and Forrest, owned by the plaintiff company. No one who remembers the state of technical knowledge at the time when the "cyanide process" first came before the public would have much hesitation in saying that at that date no practical importance had been attributed to the few and vague references in chemical literature to the solvent action of potassium cyanide on gold, or that the commercial extraction of gold by means of potassium cyanide was then distinctly novel. The step from the observation in the laboratory of the thinning and dissolution of a gold leaf in a solution of potassium cyanide, to the successful and remunerative treatment of thousands of tons of tailings by the same solution, is chemically microscopic, but commercially gigantic, and we submit that it is just this turning to commercial use of facts, latent or esoteric, which is the very essence of a patentable invention. At the risk of being tedious, we would insist once more on the need for expert assistance given to the Court as well as to the parties to the action in all cases in which technical matters are in dispute. The ease with which, in many patent cases, false analogies between dissimilar processes are presented and their acceptance secured, and the success with which essential identity is concealed by a judicious exhibition of irrelevant addenda, are deplorable and disheartening to all who, though having no interest in a contested case at the moment, are nevertheless but too keenly cognisant that it may be their turn next, and that however strong their true position, whether as possessors of a valuable patent or as genuine crusaders against an invalid monopoly, they have no ground for confidence that a legal decision will be in their favour. We are not concerned with individual affairs of any person or association liable to suffer from the results of unenlightened litigation, but in the general interest of the professional and industrial part of the community, we venture to say that a legal system which leaves the upshot of a technical case dependent upon the dexterity with which facts are presented or perverted, and almost wholly uninfluenced by the facts themselves, is a serious hindrance to legitimate enterprise and a direct incentive to ingenious expropriation.

◆

### THE SEWERAGE WORKS AT PARIS.

The scheme that is being carried out for diverting the sewage from the Seine to the extensive farms that have been established on the outskirts of Paris has taken another step forward in the construction of the first section of the aqueduct of Achères. As is well known, the comparative success of the sewage farm at Gennevilliers induced the Government in April, 1889, to pass a law authorising the construction of an aqueduct to Achères, where an extensive area of land has been secured with a view of disposing of the sewage which at present flows into the Seine at Clichy. The first part of this undertaking is the driving of a tunnel underneath the river at Clichy, and this has been successfully accomplished by M. J. Berlier, who undertook to carry out the work at his own risk by the system with which his name is so closely associated. The tube has been constructed 15 m. below the level of the Seine. It is made of cast iron plates bolted together, and covered inside and out with a hard cement, which effectually prevents any water finding its way into the interior. Its length is 463 m. Entrance is gained by a vertical shaft on the right bank of the river at Clichy. This shaft is 3 50 m. in diameter and 24 metres in depth. From the bottom of this the gallery penetrates through the bed of the Seine with a gradient of 7 mm. per metre, and then after describing a curve of 100 metres the tube inclines upward 80 mm. per metre to the left bank of the river at Asnières. At the point at which the gallery is driven there is no order whatever in the geological formation, and the material met with was composed chiefly of mud, running sand, flints, and conglomerates that had to be blown up with dynamite. Once through the hard soil at the entrance, it was necessary to employ divers and dredges, while the men in the tube had to work under compressed air. The system employed by M. Berlier is known in France as the bouclier system. The principle is, of course, by no means new, as it was employed by Brunel in constructing the Thames Tunnel, but M. Berlier has simplified the system and greatly increased its efficiency. The shield used under the Seine has a length of 1·20 m. and a diameter of 2·56 m., and is furnished with a cutting edge which pierces the soil as it advances. A cylindrical prolongation in the rear, of a slightly smaller diameter, serves to protect the wall of the gallery while the plates are being firmly bolted in their places. The apparatus is provided with a door to allow of the workmen digging out the tunnel to facilitate the advance of the shield. This forward movement is effected by five hydraulic presses, and when the shield has advanced a little more than 50 cm. the narrow plates are bolted together in the form of a ring. A space of about 3 mm. is left between the newly formed conduit and the outer wall, and this is filled up with cement, which is driven through apertures in the plates by air compressed to three or four atmospheres. The progress has occasionally been as much as 2·50 m. per twenty-four hours, but at times the in-flow of water and sand made the work exceedingly difficult. The success of this system under such drawbacks is the more interesting as it affords practical proof of its efficiency for constructing the Berlier tubular tramway across Paris, while at the same time it is held to offer some solution of the difficulties raised by the Municipal Council, who insist that the proposed Metropolitan railway shall be constructed without interfering with the thoroughfares in the city. The importance of the work added naturally to the brilliancy of the inaugural ceremony, which took place on Sunday. In the absence of M. Charles Dupuy, President of the Chamber, the Government was represented by M. Barthou, the Minister of Public Works, while among those present were M. Poubelle, Prefect of the Seine; M. Bechmann, chief engineer of the Paris sewerage works; and M. Berlier. The visitors descended into the tube, which had been brilliantly lighted with electricity, and decorated with garlands. A part of the tube had been left uncovered to show the manner in which it had been constructed, and the water that rushed through the orifices thus left open gave those present some idea of the difficulties that had to be met with. After they had traversed the tube the visitors ascended the other side, where a lunch had been provided, and after a number of speeches had been delivered the Order of the Chevalier of the Legion of Honour was conferred on M. Berlier, the academic palms were given to the assistant-engineer, M. Alain-Amiot, and commemorative medals were distributed among the workmen.

### IMPROVED FOREIGN DEMAND.

It is very satisfactory to notice that after many months of expectation an improvement in our export business in various metalliferous branches has taken place. It is to be hoped that this improvement—which is deducible from the October Board of Trade Returns—will prove lasting. In miscellaneous machinery, the business done during October as compared with the corresponding month of 1893, increased 6 per cent. This was mainly due to larger textile machinery orders from the Continent. As contrasted with a year ago, the exports of iron and steel for last month exhibited a slight decline in quantity, but this has been accompanied by a marked rise in value. The amount of iron and steel shipped was 241,270 tons, compared with 243,717 tons last year, which is a drop of about 1 per cent. The value of this tonnage, however, is set down at £1,750,126, as contrasted with £1,608,708, being an increase this year of about 8 per cent. The request for iron bars, angles, &c., has improved in value to the extent of 41 per cent.; wire, 9 per cent.; unwrought steel, 47 per cent.; galvanised sheets, 3 per cent.; and tin plates, 43 per cent. In consequence of the reduced duty on the latter product coming into force on October 1st, the shipments to the United States were exceptionally large, being 24,854 tons last month, against 13,816 tons for the same time in 1893. Turning to metals, we find that copper and brass have been in better demand. The former has improved by over 7 per cent. in all, unwrought copper having increased by 33 per cent., and mixed or yellow metal sheathing by 7 per cent. It is also gratifying to find that hardware and cutlery show an increase of 14 per cent., the value of October's shipments being £117,936, as against £103,035 in 1893. It is very satisfactory, after the many complaints of continental competition, to observe that our shipments of hardware last month included augmented consignments to Germany, Holland, and Belgium, while with all these countries we have done a larger business also in the past ten months than in the corresponding period last year.

### STEEL AND IRON STEAMERS.

The question of the relative liability of iron and steel steamers to accident and loss is being very keenly canvassed in the north-east and in some other parts at the present time, and the experience of some of the mutual marine insurance clubs is being analysed to see how far the popular idea of the superior safety of the steel steamer is proved. Some of the figures that have been compiled certainly go far to show that the steel steamers, whether from age or other conditions, have cost much less so far than iron ships in similar trades. For instance, one northern club had last year 427 steamers, iron and steel, insured; and the average cost of the whole of these was about £9 2s. per cent. in the case of iron steamers of a certain value, whilst that of the steel steamers of the same value was £4 8s. 5d.—a difference that is startling, but one that is verified by the experience of vessels at other values, and is also confirmed by the experience of other clubs. It is found on analysis that the difference is most remarkable in the assessment to total loss, though it is also found in cost of repairs, &c., that are needed. For instance, in one year, the cost per cent. of steel steamers was only 8s., whilst that of the iron steamers was for the same year £5 9s. 10d., and the cost for particular average is to add to this. It is possible that the youth of the steel steamers may in some degree account for this great disparity; but as most of our vessels are now being built of steel, it is evident that the average age of the iron steamers will grow greater, whilst the average age of the steel steamers will be kept down by the constant addition of fresh tonnage. The matter is one that is now exciting very great attention, because so wide a difference means that the steel steamer has in the last few years been paying a considerable part of the cost of the insurance of the older iron vessel, and this is a condition of things that is not likely to be allowed to continue very long.

## LITERATURE.

*The Incandescent Lamp and its Manufacture.* By G. S. RAM. London: Electrician Publishing Company.

*Alternate Current Transformers.* By R. W. WEEKES. London: Biggs and Co. 1894.

*Alternating Currents.* By BEDELL and CREHORE. Second edition: New York, the W. J. Johnson Company; London, Whittaker and Co.

*A Manual of Telephony.* PREECE and STUBBS. London: Whittaker and Co. 1894.

The appearance of Mr. Ram's book upon the incandescent lamp seems to be chiefly due to the expiration of the Edison master-patent for the carbon filament, and to the consequent revival of public interest in the process of manufacture. There is very little literature upon the subject, the best account hitherto being the series of articles by Mr. Swinburne which appeared some seven years ago in the *Electrician.* This book is evidently written by a thoroughly practical man, as the details of the processes are carefully described. It appears that the original method invented by Swan for the treatment of cotton threads is still unsurpassed for the manufacture of filaments, although numerous processes have been invented by others. The author follows the whole process throughout, giving careful directions for the avoidance of damage to the filaments during manufacture. No satisfactory substitute has been yet discovered for platinum, but the supply of metal appears to keep up with the demand. In the chapter describing the flashing of the filament, the author gives curves showing the effect of the flashing upon the resistance of filaments of various diameters. A very full description of glass blowing as applied to this special work is included, and much of the matter is evidently condensed from notes taken in a lamp works by the author. Exhausting is best carried on while the lamps are heated to near the softening point of glass, as whatever mercury vapour and air is left in the bulb will of course be left at a much lower tension when the lamp becomes cold. We perfectly agree with the author that a great deal of valuable time has been spent in making life tests of incandescent lamps. In most of the recorded cases no actual tests of candle-power of the lamps at various stages are reported. The work is eminently adapted as a text-book for lamp manufacturers.

The small book upon transformers, by Mr. Weekes, is intended to facilitate the design of apparatus which shall be as efficient as possible at light loads. The principal point to which attention was at first given in alternating current distribution was efficiency at full load, but with improved knowledge that is now found quite insufficient. Higher mathematics have been avoided, which, of course, necessitates the acceptance without proof of some of the well-known formulæ. Free use has been made by the author of Dr. Fleming's work, and his results are given in tabular form. The vital difference between the number of watts required by a consumer from the central station in the case of an efficient and non-efficient transformer is well brought out by numerical examples.

Perhaps the most valuable part of the book is the description, with dimensioned sketches of various types, of apparatus now in use, and well-deserved praise is accorded to the results obtained with the Westinghouse transformer. The author states that if a station were equipped solely with Hedgehog transformers, at least 40 per cent. of the plant would have to be worked continuously. He points out that if the transformers of this type be placed close together the result is a closed circuit transformer. The work should be of interest to all electricians engaged on the alternate current system.

The volume before us, by Messrs. Bedell and Crehore, is a more ambitious work than that just alluded to; the authors do not attempt to shirk a full mathematical treatment of the subject. The preface is dated from Cornell University, and the book is divided into two parts, the analytical and the graphic. In the first part the discussion of circuits containing resistance and self-induction only is taken up, and the treatment is based upon elementary principles. The case of circuits containing resistance and capacity is then dealt with, and finally the subject of circuits containing resistance, self-induction, and capacity is taken up, the same order of treatment being followed as in the previous cases. The work can only be read by persons familiar with the differential and integral calculi, and a chapter is devoted to the discussion of harmonic functions. Few transformer manufacturers have received sufficient mathematical training to make use of the book.

The manual of which Messrs. Preece and Stubbs are joint authors is one of the books in the "Specialist's Series." In November, 1888, a volume entitled "The Telephone" was brought out by Messrs. W. H. Preece and Dr. Maier, and that work is practically incorporated in the present one. This volume is of a very complete character, beginning with a historical sketch of the telephone. The construction of receivers and transmitters is then described, and wherever possible the illustrations are not mere views of the exterior, but are line drawings to scale, and the scale is noted upon each figure. References are often given to the patent specifications, so that exact details may be obtained of the claims and novelty put forward by the inventors. One of the divisions of the book contains a considerable amount of information respecting simple exchanges. This is a subject of much importance, about which little has been published in book form in this country. In Part IV. the important subject of multiple switches is dealt with, and the authors lay great stress upon the desirability for a careful study of the best methods of installing a large exchange. The latter portion of the work deals with the construction of telephone lines of the aërial, subterranean, and submarine type, and the Post-office specification is given. The divergencies between authorities on the electrical and other qualities of the standard gauges of copper wire have led the authors to entirely re-calculate the tables given in the appendix. A useful scale for the joint resistance of two conductors will be found which obviates calculation. The authors are careful to give the exact data upon which they have calculated the tables, so that the reader can be under no misapprehension. The work is certainly the most complete we have seen on the subject.

## *BOOKS RECEIVED.*

*Integral Calculus for Beginners, with an Introduction to the Study of Differential Equations.* By Joseph Edwards, M.A. London: Macmillan and Company. 1894.

*Engineers and their Triumphs. The Story of the Locomotive, the Steamship, Bridge Building, Tunnel Making.* By F. M. Holmes. London: S. W. Partridge and Company.

*A Text-book of Mechanics and Hydrostatics.* By Herbert Hancock, M.A., F.R.A.S., F.R. Met. Soc. With nearly five hundred diagrams. London: Sampson, Low, Marston, and Co. 1894.

"*Direct Calculator*" (*Ds.*) Price 6s. 6d. By M. B Cotsworth. Showing at a glance the values for all weights from 7 lb. to 1000 tons at all rates to £100 per ton. Printed by McCorquodale and Co., Leeds, and published by Crosby Lockwood and Son, London. 1894.

*Electric Lighting and Power Distribution.* An elementary manual for students preparing for the preliminary and ordinary grade examinations of the City and Guilds of London Institute. By W. Perren Maycock, M.I.E.E. 282 illustrations and diagrams. London: Whittaker and Co. 1894.

*Electric Light Installations. Vol. I.—The Management of Accumulators. Vol. II.—Apparatus. Vol. III.—Application.* A practical handbook. By Sir David Salomons, Bart., M.A. Seventh edition, revised and enlarged. With illustrations. London: Whitaker and Co., George Bell and Sons. 1893.

*The Railway and Traders' Calculator.* Showing at a glance by index all rates from the 100th part of 1d. to £5 per ton, for all weights from 1 lb. to 1000 tons, in all over 250,000 direct calculations. By M. B. Cotsworth. Second edition. Printed by McCorquodale and Co., Leeds. London: Published by Crosby Lockwood and Son. 1894.

## LEEDS ASSOCIATION OF ENGINEERS.

### COLLIERY WINDING ENGINES.

At the last monthly meeting of this Association a paper was read by Mr. J. Clark Jefferson, A.R.S.M., on "Balancing the Load on Colliery Winding Engines." The most economical and perfectly developed type of steam engine, he said, was probably the marine engine. The very opposite was the case with most winding engines, owing to their intermittent action and the great alteration in the loads. The latter drawback was due to the variation in the lengths of the coiling and uncoiling ropes during the raising of coal, necessitating, in the case of shafts of comparatively moderate depth, an engine of double the power to what would be required were the load even approximately uniform. The attempts to render it so divided themselves into two classes: First, those which aimed at an actual balancing of the weight of the rope; and secondly, those which varied the leverage of the engine during the course of the winding, to counteract the alteration due to the changing lengths of suspended rope. The former class comprised balance chains, balance weights suspended in staple pits, or hauled up and down straight or curved inclines, balance ropes, the tail rope and Koepke system. All these methods—although the balancing might be perfectly effected—possessed two disadvantages. The total weight to be moved being greater, the frictional and other resistances were increased, and the deteriorating effect on the winding rope near its junction with the cage necessitated its more frequent shortening, and reduced the life of the rope. Meinicke's system, in which the balance rope is attached to auxiliary ropes, which are wound and unwound from a separate drum on the winding axle, obviated this difficulty, but required a larger amount of rope. This objection was more apparent than real, since discarded winding ropes could be used up as auxiliaries. The alteration of leverage was effected by using conical or spiral drums instead of cylindrical ones. Some degree of compensation always took place where the load was raised by a flat rope coiled upon itself. A probable reason why conical drums had only to a slight extent been used was that the principle of designing them had not been sufficiently known. The main point in their design was not in the proportion of diameter and breadth. These might be varied within very wide limits, and still agree with the conditions of keeping the load uniform. This could only be ensured by preserving a proper ratio between the large and the small diameter of the drum, such ratio being dependent only on the respective weights of the cage, empty corves, coal, and the fully unwound rope. Mr. Jefferson gave the required rules and formula, and, by means of diagrams of mean turning effort, the effect of improper design was illustrated.

The formula giving the ratio between the large diameter $D_1$ of the drum and the small diameter D is

$$\frac{D_1}{D} = \frac{B + \sqrt{B^2 + \frac{1}{2}} + 2}{B + \sqrt{B^2 + \frac{1}{2}} - 2}$$

in which $B = 1 + \frac{W + 2C}{R}$ and W = weight of coal raised at one winding, C = the weight of the cage and empty corves, and R = the weight of one of the ropes. The best method is to determine first the smallest diameter of drum suitable for the rope, and afterwards the large diameter by the above formula. A very close approximation to the above formula is obtained by making the effective turning moment at the commencement equal to the effective turning moment at the end of one winding, viz:—

$$\tfrac{1}{2}(W + C + R)D - \tfrac{1}{2}C D_1 = \tfrac{1}{2}(W + C)D_1 - \tfrac{1}{2}(R + C)D$$

$$\text{or } \frac{D_1}{D} = \frac{W + 2C + 2R}{W + 2C}$$

The smallest diameter of the drum $D = \frac{\epsilon\,\delta}{T - t}$ when $\epsilon$ = modulus of elasticity; $\delta$ = the diameter of one of the wires; T = the maximum allowable tension per unit sectional area—which occurs where the wires are on the outside of the rope; and $t$ the mean allowable average tension of the wires. Owing to the comparatively large value of D as given by the above formula, Mr. Jefferson said it was necessary to keep the piston velocity moderate—especially in the case of comparatively shallow pits—otherwise the piston stroke became excessively large relatively to the diameter of the cylinder.

A discussion followed, in which Messrs. Atkinson, Drake, Tempest, and Hargreaves took part. A vote of thanks was accorded to the author, on the motion of Messrs. Bowers and Lupton.

The approximate statement of traffic for October on the Manchester Ship Canal gives a total tonnage of 97,784 tons and £8200 receipts. From January 1st last to Octotober the total tonnage is given as 717,967 and the total receipts as £70,694.

## MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY.

### EXTENSION TO LONDON.

BETWEEN eleven and twelve o'clock on the morning of Wednesday, the 13th inst., a large number of gentlemen arrived at St. John's Wood Station, and inquired for Alpha-road. The majority of them came from Yorkshire, of which county they represented the commercial, fishing, colliery, railway, agricultural, municipal, and other interests; but there were also visitors from Manchester, Nottingham, and other places on the new line, including Aylesbury, near which it is to make its junction with the Metropolitan. As had already been announced, at twelve noon the Countess of Wharncliffe was to turn the first sod of the extension of the Manchester, Sheffield, and Lincolnshire line to London, and thus denote that the efforts of the directors to connect their system with the metropolis had at last been successful.

The Earl and Countess of Wharncliffe arrived on the ground at five minutes to twelve, and were received by Sir E. W. Watkin, M.P., who has happily nearly recovered from his recent severe illness. Amongst the number of well-known men who were present may be mentioned Lord George Hamilton, the Marquis of Granby, Mr. Herbert Gladstone, M.P., Mr. Broadhurst, M.P., Sir F. Seager Hunt, M.P., Mr. J. S. Forbes, Sir Frederick Bramwell, Sir George Bruce, Sir Douglas Fox, Major-General Hutchinson, R.E., and Major Marindin, R.E., of the Board of Trade.

The proceedings commenced with a special prayer by the Rev. R. H. Pigott, rector of Grendon, near Aylesbury, who alluded to the coal, fish, and farm produce which would, by the instrumentality of the new line, be supplied more cheaply and abundantly to the millions of the metropolis. He also prayed that those engaged in the construction might be preserved from danger or accident. Sir Edward Watkin then rose, and was received with great applause. He commenced by asking the Countess to accept the barrow and spade, which he presented on behalf of himself and the other directors of the Manchester, Sheffield, and Lincolnshire Railway. These are both of English oak, beautifully carved, and ornamented with silver, of which metal the blade of the spade is also formed. In speaking of the ancestors of the house of Wharncliffe, he alluded to Lady Mary Wortley Montague, who first introduced inoculation into this country. The countess then entered the space railed off in the centre, and energetically dug up a piece of turf. With the assistance of Mr. Fox's umbrella, this was deposited in the barrow, which her ladyship then wheeled to the end of a 22ft. plank, and tipped the turf out. Lord Wharncliffe, in thanking those present for attending, and Sir Edward, on Lady Wharncliffe's behalf, for his speech, and for the barrow and spade, said that he was pleased to see his old colleague there. He remarked that he had been a director of the line since 1864, and though he had not always agreed with Sir Edward, he had always esteemed him greatly, and they had worked well together. He added, that when he joined the Board, he little thought he should ever be called on to preside at an occasion like the present. The idea of connecting the line with London, and the work entailed in carrying out that project, were both to be ascribed to Sir Edward, and he felt like the man who had assumed the credit of Virgil's verse, and of whom the poet wrote:—

> "Hos ego versiculos feci, tulit alter honores."

After a genial allusion to "another place," where he hoped shortly to meet all those who were present, he concluded; and that part of the ceremony terminated by the band playing "God save the Queen."

The visitors, who numbered about 500, were then driven to the new King's Hall of the Holborn Restaurant. After an elaborate banquet, and the usual loyal toasts, Lord George Hamilton proposed "Success to the New London Line." He said he doubted whether many of those present appreciated the nature, magnitude, and complexity of the difficulties that had been encountered and surmounted. Owing to the diversity of interests touched, the approach to the city had to be fought inch by inch, more after the manner of an invading army approaching a hostile capital than peaceful men in pursuit of business. He alluded to their difficulty with regard to Lords' Cricket Ground, and explained how it had been overcome to the benefit of both parties; and he pictured a Yorkshire County Eleven coming up over their line, and returning victorious as the premier county in England for cricket. He added that a railway company which could obtain a station in London received a pulsation through its system from that great heart, giving it prestige and vitality, which were felt in every part of its district.

The chairman, in replying, said that they had followed the example of the other great companies of England in extending their mileage. At present they had 355 miles of independent line, and 207 which they held jointly with other companies. The part to be constructed was 98 miles, from Annesley to Quainton-road on the Metropolitan, near Aylesbury. He then gave details of the part of their traffic which was sent up on other lines, and showed that it averaged 66 per cent., or two million tons, of which 80,000 tons was fish from Grimsby.

After the health of Lady Wharncliffe had been proposed by Sir E. Watkin, and that of the Chairman by Mr. R. D. M. Littler, Q.C., who was the leading counsel for the promotion of the Bill, there was a speech by Mr. J. S. Forbes, chairman of the London, Chatham, and Dover Railway, which was not on the printed programme. He said that this gathering was the visible manifestation of a great idea, conceived by a great man, and carried out with great tenacity of purpose. He expressed his admiration and friendship for Sir Edward Watkin, and amidst loud applause, proposed his health. The health of Mr. W. Pollitt, General Manager of the Manchester, Sheffield, and Lincolnshire Railway, terminated the proceedings.

From Annesley the new line will pass through Nottingham, Loughborough, Leicester, Lutterworth, and Rugby, to its junction at Quainton-road. From this station the Manchester, Sheffield, and Lincolnshire line have running powers over the Aylesbury branch of the Metropolitan. At a point between Wembley Park and Willesden they will branch off from the Metropolitan, and come into their independent terminus station, which is to be built near the spot on the north side of Alpha-road, where the first sod was turned. This terminus, including sidings, coal sheds, &c., will cover a space of about sixty-six acres. The contract for the new line has been divided into six sections, the time allowed for completion being two and a-half years, so that we may expect to see it finished in the course of 1897.

THE MANCHESTER, SHEFFIELD, AND LINCOLN PROJECTED NEW LINE TO LONDON

## ABSTRACTS OF CONSULAR AND DIPLOMATIC REPORTS.

*Japan: Coal in.*—In coal the Japanese are active competitors with English producers. In 1893 the export rose to 1,505,413 tons, an increase of 605,015 tons, or 67·1 per cent. over that of the previous year, while the value fell from 9s. 1¾d. to 8s. 2⅜d. per ton. Japanese coal is rapidly pushing its way westward, and is already largely used by ships coaling at Singapore. Last year about 480,000 tons of coal, and 173,000 tons of so-called coal dust were shipped to that place, Hong Kong, and British India. To this quantity must be added a large proportion shipped in steamers nominally for ships' use, but in reality for purposes of trade.

*Japan: Coal in Hiogo and Osaka.*—Last year the export of coal fell to 52,238 tons, a decrease of 5812 tons, or 10 per cent. under that of 1892, and in value from 12s. 8½d. to 9s. 11$\frac{1}{10}$d. per ton. The incalculable harm done by the recent lamentable struggle in the English coal trade has made itself felt in the Far East, and Japanese colliery owners are reaping temporary if not permanent advantages. The effects of the coal strike are felt even in Kobe, the price of Moji coal having risen considerably. Before the opening in 1888 of Moji, situated in Kiushire and opposite to Shimonoseki, Singapore was the last coaling station on the way home and the first on the way out. Until the strike English coal only was taken at Singapore, but now Japanese coal is principally supplied. The bad example set by Westerners in their manner of settling trade disputes is being followed by the Japanese, and during the past eighteen months there have been several strikes among them, one by the miners at Takashima, near Nagasaki.

*Japan: Coal in Nagasaki.*—Last year the import of Cardiff coal, solely for the use of foreign ships of war, fell to 2660 tons, a decrease of 3561 tons, or 57·25 per cent. under that of 1892, but increased in value from £1 8s. 1½d. to £1 9s. 5d. per ton. The total exports of coal from this port during the year were 381,631 tons, a decrease of 36,646 tons, or 8·75 per cent. The value fell to £156,459, a decrease of £63,834, or 29 per cent. Coal for ships' use increased by 20,651 tons, or 16·15 per cent., but decreased in value from 11s. 6¾d. to 9s. 5d. per ton. Coal other than for ships decreased by 44,943 tons, or 23·45 per cent., and in value from 10s. 2¾d. to 7s. 6⅜d. per ton. Dust coal decreased by 12,353 tons, or 12·65 per cent., and in value from 9s. 9¼d. to 7s. 2d. per ton. The net output of Takashima coal during the year was 252,320 tons, of which 127,016 tons were large, and 125,304 tons small coal. The sales were 286,784 tons, divided into 150,242 tons small, and 136,542 tons large coal. The destinations and quantities were:—

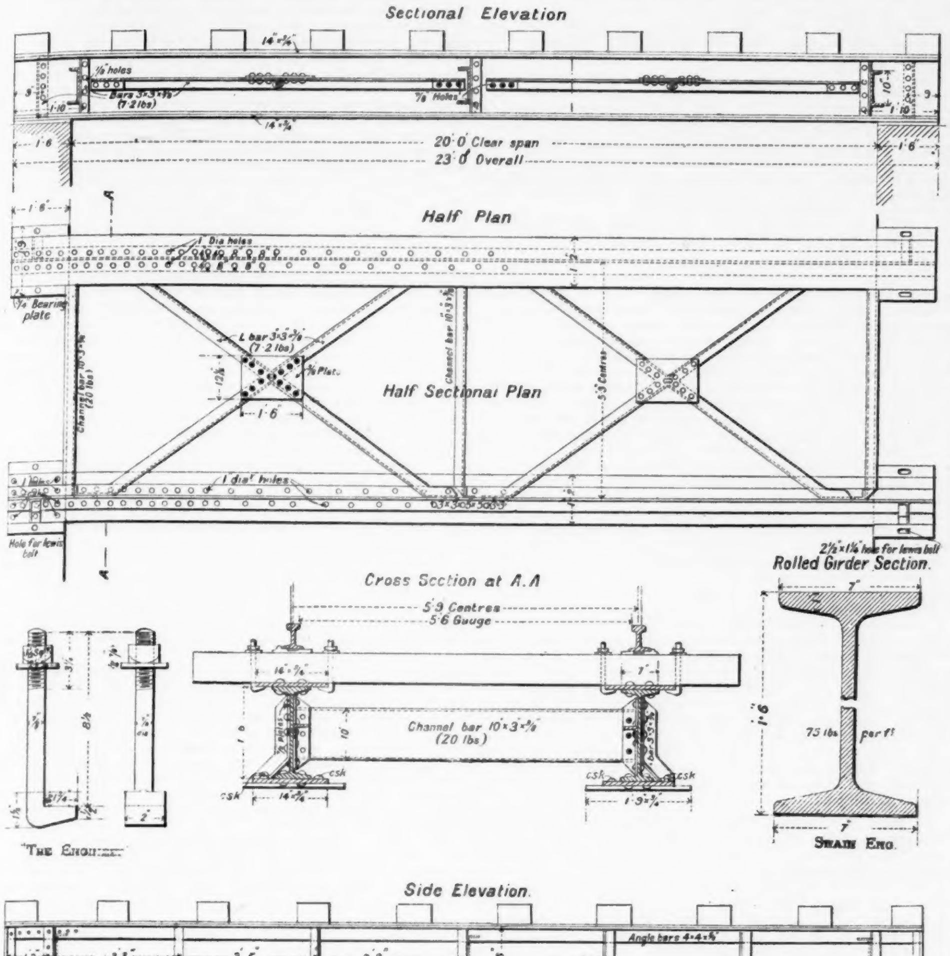
| Ports. | Quantity. | |
|---|---|---|
| | Small Coal. Tons. | Large Coal. Tons. |
| Hong Kong | 37,990 | 11,935 |
| Shanghai | 34,514 | 14,085 |
| Yokohama | 2135 | 25,175 |
| Osaka | 7001 | 584 |
| Singapore | 5270 | 11,627 |
| Three other ports | 391 | 4231 |
| Bunkersete | 62,941 | 68,925 |
| | 150,242 | 136,542 |

The stocks of Japanese coal available on December 31st, 1893, were only about 3000 tons, and through the year the mines were unable to meet the foreign demand, local shipping requirements consuming the greater part of the output. While the export of coal from this vicinity decreased, the export from the special ports rose to 990,112 tons, an increase of 281,378 tons, or 39·7 per cent., valued at 7s. 9¾d. per ton. The quantities exported from the various ports were:—Kutehrnotsu, 452,524 tons; Moji, 431,259 tons; Thimonoseti, 64,037 tons; Karatsu, 42,292 tons; total, 990,112 tons.

*China: Coal in Formosa.*—Last year the exports of coal from Tamsui and Ketung rose to 23,748 tons, an increase of 9245 tons, or 63·7 per cent. over those of 1892, but decreased in value from 12s. 2¼d. to 10s. 1½d. per ton. During the year the supply was altogether from private pits; the Government mine remaining idle, and the machinery, still *in situ*, being rusted and ruined owing to neglect, and to the water standing in the disused workings. The seams in the immediate neighbourhood of the Government mine have been — at least nominally—forbidden ground for private enterprise. Formosa coal is splendid house coal. It is also good, if smoky, steam coal, though not equal to Japanese; but it must be borne in mind that none but surface coal is available here, whereas that produced in Japan is mined from deep seams, and were mines of the same character allowed in Formosa the quality of the output would improve.

*China: Coal for Honyang Ironworks.*—Coke to the amount of 3000 tons has been ordered from Belgium to be used in smelting operations at these works. This seems somewhat curious considering that we have coal on all sides of us, but apparently none suitable for the purpose has yet been discovered, though there is said to be an abundance of the right sort in the Hunan province. The United States Consul at Hankow observes on this point:—Coal both hard and soft is mined in the neighbourhood in the crudest manner, no effort being made to drain the mines of water, which, once flooded, are abandoned and new ones opened. The coal has been pronounced by experts as not suitable for smelting, as it contains too much sulphur, but it is thought that coal of a good

## CONTRACTS OPEN—GIRDERS FOR INDIAN RAILWAYS



quality can be obtained hereafter from the mines now undeveloped. Mines of coal and iron are numerous in this section, and can be made to furnish all the material needed if mined systematically, and owing to the cheap labour obtainable they can be worked economically.

*China: Coal in Jehang.*—Last year 651 tons of soft coal were brought down from the mines in the west of this province, Hupei. None of these mines are worked scientifically, but are merely scratched in the old-fashioned Chinese manner. Hard coal is found at a place called Ching Mên Chow, about seventy miles below Jehang.

## CONTRACTS OPEN.

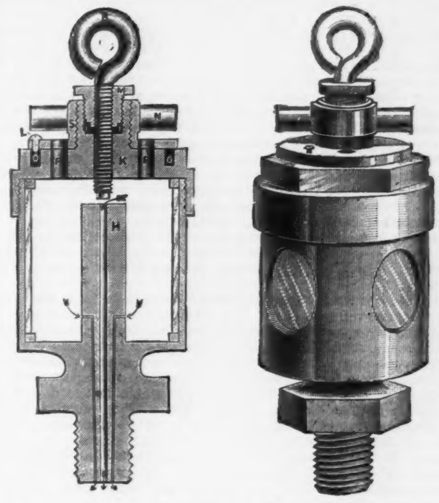
### INDIAN STATE RAILWAYS.—OUDH AND ROHILKUND RAILWAY FIVE FEET SIX INCH GAUGE.

The work required under this contract comprises the construction, supply, and delivery in England at one or more of the ports named in the tender — London, Liverpool, or Birkenhead — of the whole of the steelwork for 61 spans of 20ft. in the clear, including all bolts, rivets, &c., required to complete the erection of the bridges in India, together with an allowance for waste, &c., of 10 per cent. on the net quantity of bolts required, and 50 per cent. on the net quantity of rivets required of the proper sizes for the purpose. In addition to the above, the contractor is to supply with each span, service bolts and nuts and ordinary plater washers to be selected by the consulting engineer, for use in the erection of the work in India in the following proportions: —With each 20ft. span 28 lb. of bolts and nuts, and 14 lb. of washers. The work is shown on drawing No. A 1252, but firms are also at liberty to submit a tender for the alternative design drawing No. A 1253.

Firms tendering are to submit with their tenders the names of the makers from whom the steel for the various parts of the girders will be obtained, the character of the steel employed, *i.e.*, whether open hearth basic, or Bessemer, or open hearth acid, and the nature of the ores to be used in making it. Basic Bessemer will not be accepted, open hearth acid is preferred. Tenders are to be in by two o'clock on Tuesday, 20th November, 1894.

## WILLCOX'S CRANK-PIN LUBRICATOR.

The part H shown in Fig. 2 of the engravings illustrating this new lubricator is an easy fit in the lower part of the lubricator. When the lubricator is moved up and down as in the circular path of a crank-pin, this piece H pumps up and down by an amount which is adjustable by the screw R. Each time the piece H moves upwards through the permitted range, some oil finds its way round the stem of H and into it as indicated by the arrows, and the piece H thus acts as an induction pump. The cup is of glass, and is filled by turning the handle N, and placing holes P opposite each other in the piece K, and in the cover. It is made specially for the crank-pins of engines, pumps, &c. There is no waste of oil when the crank is standing, as the piston sits on to its seating, and thus closes the outlet. There is also no trouble in adjustment when once the screw is set, the re-filling not affecting this. The lubricator is simple and safe, and it is now being used on traction, portable, and fixed engines, and for gas and oil engines. It is made by Messrs. Willcox and Co., Southwark-street, S.E.



## LEGAL INTELLIGENCE.

### HIGH COURT OF JUSTICE.—CHANCERY DIVISION.

*November* 10*th*, 1894.

(*Before* Mr. Justice Stirling.)

WISE *v.* THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

In this case the plaintiffs had in April last obtained an injunction against the company, restraining them from carrying on their works at Manchester-street, W., so as to cause a nuisance to the plaintiffs by vibration. The operation of that injunction was, however, suspended until September 5th. It will be remembered that the defendant company have established a large electric-lighting station in the neighbourhood of Manchester-street, and the plaintiffs, who are householders and lodging-house keepers in the vicinity, complain of a nuisance caused by the vibration of the machinery. At the hearing of the action for an injunction, it was proved that such vibration did exist to a serious extent. Owing to the peculiar nature of the soil upon which the works are erected the task of prevening the vibration of the machinery from being communicated to the surrounding houses presents an engineering problem of great difficulty. At the time of the granting of the injunction the company were, under the advice of eminent engineers, endeavouring to overcome the difficulty by works intended to increase the rigidity of the bed or platform upon which the engines are rested, and, although their operations in that direction were partially successful, they do not seem to have been entirely so, for the company have, since the injunction, come to the determination to substitute for the reciprocating engines hitherto in use a new class of engines called steam turbines, which, it appears, can be used without causing any vibration. The company have accordingly removed some of their old engines to another of their stations, and have already erected one turbine and ordered two others, which, when in position, will it is hoped enable them to supply all the necessary electric energy without using any of the old class of engines. In the meanwhile, the plaintiffs alleged that, in spite of the injunction, the company have allowed the nuisance to continue, and they now moved for leave to issue a writ of sequestration against the company. A great mass of evidence was read on either side, that of the plaintiffs, as the *Times* reports, tending to show that there had been very little, if any, abatement of the nuisance, and that of the company being to the effect that, since the granting of the injunction, there had been no such vibration caused by the engines as amounted to a breach of the order, and that they had almost, if not altogether, succeeded in overcoming the engineering difficulties.

At the conclusion of the evidence on the 9th inst., his Lordship asked if the company were willing to undertake not to use more than one reciprocating engine, besides the turbines, for a period of three weeks, and, upon counsel for the company consenting to that, his Lordship said that it appeared to him, upon the evidence now presented to the Court, that if the company worked three engines of the reciprocating class a nuisance would be caused, but if they only used one there would be no such vibration as to amount to a breach of the injunction. He was anxious to be satisfied by a further experiment that that was so, and under these circumstances he should direct the motion to stand over for three weeks upon the above undertaking by the company.

The counsel appearing in the case were Mr. Hastings, Q.C., and Mr. Beaumont for the plaintiffs; Mr. Vernon Smith and Mr. Waggett for the company.

In an article on washing and conditioning wheat in *The Miller*, the writer, Mr. W. T. Bates, summarises a lengthy consideration of the different processes of machinery, saying a washer and drier is a useful auxiliary in every mill, because it enables every kind of wheat to be used to the best advantage. "Next to heat, and failing it, have a good arrangement for carefully damping any sample separately for re-cleaning, and also for damping the mixture whenever requisite. By the first process I should treat all palpably dirty wheat, such as Egyptian, Indian, Russian, River Plates—when necessary—and some kinds, like Chilian, which have mineral or stoney impurities difficult to get out by any dry process. By the latter—that is, simple damping—I should treat all other clean wheats, like North American, Australian, Californian, and any other which is likely to become pulverised in the break rolls. The degree of moisture can be regulated to their needs, and excellent results thereby obtained."

# LETTERS TO THE EDITOR.

*(Continued from page 425)*

## RAILWAYS AND THE BOARD OF TRADE.—ELECTRIC TRACTION FOR LIGHT RAILWAYS.

SIR,—I beg to express my thorough appreciation of and concurrence in the remarks in your editorial on "Railways and the Board of Trade" on page 345. While giving due credit for the good work which the Board has done in the interests of the public as far as main lines go, there is little doubt that it has most seriously retarded the construction of the less important lines which fill in, or should fill in, the spaces between the main routes. To what extent the Board and its agents—the inspectors—are limited by the railway laws as now existing, I am not able to say, and it would be worth while to have this part of the question taken up. Be this as it may, however, there is very evidently but one standard of railway construction considered by the Board, owing either to the limitations of the law, or its own limited conception of the principles of railway economics. It is as though a Government Bureau should say that any man wanting to keep a horse must keep blooded animals, and drive a carriage and pair. A few years ago, while travelling over a lightly but well-built and economically-operated railway in a thinly populated district, which railway connected an outlying small manufacturing town with a main line, I was talking with the engineer about the cost of construction and equipment. In answer to a comment upon the lightness of certain works, and the small total cost of the line, he said, "We could not afford to buy a horse, so we bought a donkey." In England, however, you must have a horse or you must walk.

It seems to me that a great deal of the trouble lies in the failure to recognise the true purpose of a railway, and to recognise the error of trying to place all railway construction on the same basis. Take roads, road vehicles, and steamships for instance. We have expensive paved streets for heavy city traffic, and cheaper macadamised roads for country traffic. Luxurious carriages convey the wealthy passenger, while the less wealthy ride in the democratic omnibus or the humble donkey cart. The magnificent fast steamers carry the first-class freight, which has perhaps been brought to Liverpool by a tub of a coasting steamer or a canal boat. So with railways, it is right enough to insist upon expensive construction, complete signal plant, &c., for main lines with fast and heavy traffic. But it is absurd to impose the same conditions upon a branch line with but few trains. If the law compels this, the sooner a new law is passed, based on a more accurate understanding of the purposes of a railway, the better, and those who are working in favour of better railway facilities should turn their energies in this direction.

As to the employment of military officers on railway work, the principle is wrong from the bottom, as experience has proved in England and India. It is the system that is wrong, not the men, who, in most cases, are no doubt conscientious and high-minded, but lack the practical experience and training which alone can fit men for such positions. Imagine a civilian—say a banker or merchant of high standing—appointed to the command of a military post. He might after a time be very well able to look after routine matters, but what sort of figure would he make in conferences as to the use of shields on light field pieces, or the advantages of bullet-proof breast-plates, or how would he handle men in the field? If, in the latter case, he moved his men always and only in the few formations he had seen on the parade ground—not understanding the importance of or being able to take advantage of local conditions—he would do no worse than the military officer who knows that certain very excellent railways are built and equipped in a certain way, and therefore decides that no railway must be operated unless built and equipped in a similar way. It is like requiring cavalrymen to wear full uniform while watering their horses or fetching forage, and having the band play an accompaniment to the work. Even the theoretical safety derived from a complete signal and block system equipment is not always obtained on the cross-country railway, for, as experience has shown in certain cases of accident, the railway companies do not feel disposed to pay wages to get the best class of men, or the men regularly and wilfully ignore the signals or orders.

A revision of the law, a revision of this one-standard system of railway construction, and a revision of the absurdly-expensive and tedious system of parliamentary procedure, are needed badly and needed at once. Supposing such revisions made, the practical possibilities of economical railways need little demonstration. Other countries have shown what can be done, and English business men, engineers, and managers can do as well if they will. But I wish to call attention to one special class of economical railway which is being developed very rapidly in this country, and that is the country electric railway. The extension of suburban railways has been a most important factor in the development of large cities, enabling the lower and middle working classes to live in healthy suburban houses instead of crowded city houses or tenement dwellings. This is even more true of the electric railway than of the suburban service on an ordinary steam railway, as the former gives a better accommodation owing to the almost constant service of cars and the greater number of stops, while high speed can easily be reached and reduced with a single car. Another special feature of such railways is their construction to outlying parks, pleasure resorts, or beaches, enabling the people to obtain pure air and new scenes for the expenditure of a few pence. In some cases, where the value of new building property will be greatly increased, the owners will give the land for the railway, which may then be operated to greater advantage than where built along the highway. Herein is matter for consideration by the public authorities and tramway companies of English cities.

In several cases suburban or interurban electric railways have been built approximately parallel with steam railways, and have absorbed a large proportion of the local traffic of the latter, owing to generally reduced fares, and to the fact that for the steam railway a man has to live up to a time-table and calculate his time to catch a certain train, while for the electric railway he knows that he has a car every few minutes. Many electric railways of this class now handle mail, parcels, and goods traffic. Mail sorting cars are run, exchanging bags with postmen at certain points. Parcels are carried in combination passenger and baggage cars, being collected and delivered at offices at the ends of the line. Farm produce, milk, &c., are brought into cities on special cars in the early morning, and at one town on the Hudson River special cars bring the milk cans from the farms to the wharf, where they are loaded on the steamer for New York city. On other lines, built as feeders, grain is hauled between the railway station and the flour mills, coal is carried—sometimes in ordinary railway cars—and raw material and finished product are carried between the railway and small manufacturing towns. Where there is much freight or goods traffic, electric locomotives are sometimes used, but otherwise motor cars are used, having motors on the axles, such cars hauling "trail cars." I know of one line, seven miles long, serving five or six suburban towns and villages, on which electric traction has been substituted for steam, ordinary tramcars being used. This line has two mail sorting cars. The construction and equipment of such lines are cheaper than for branch lines of ordinary type, while the accommodation is better, and the cost of operation usually much less. There is little objection to or difficulty with the overhead wires in country roads, and still less where the line is on its own land. Where such objection is insuperable, however, some form of independent motor operated by steam, compressed air, gas, &c.—such as the Rowan, Lamm-Francq, Mekarski, Luhrig, or other systems—may be used, the important requirements being that such motors must be light in weight, powerful, clean and noiseless, reliable, and economical in operation.

Your correspondent, Mr. Bowles, points out the uneconomical method of operating in using two engines and tenders, weighing in all 162 tons, to haul cars weighing 194 tons, and it may be of interest to give here the weights of some regular express trains in this country. The weights are net tons of 2000 lb.:—

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Weight of engine and tender, tons | 88 | 88 | 86 | 88 | 88 | 88 | 100 | 100 |
| Weight of cars .. | 222 | 292 | 432 | 237 | 309 | 320 | 475 | 321 |
| Weight of train .. | 310 | 380 | 518 | 325 | 397 | 408 | 575 | 421 |
| Speed, miles per hour .. .. .. | 49 to 55 | 35 to 60 | 43 | 45 to 57 | 40 to 60 | 40 to 73 | 40 to 60 | 47 |
| Length of run, miles | 134 | 117 | 132 | 90¾ | 90¾ | 90¾ | 440 | 148 |

Finally, to return to the first subject of this letter, I would suggest that some investigation be made to ascertain just how far the Board of Trade is limited by law, and how far by prejudice and lack of experience; and also that some steps be taken to remove obstacles in the way of *bonâ fide* projects for economical construction and operation of secondary railways.

E. E. RUSSELL TRATMAN, Assoc. Mem. Am. Soc. C.E.
Tribune Building, New York, U.S.A.,
November 1st.

SIR,—The letter which has been addressed to the Chambers of Commerce, railway companies, and other bodies interested in transport, by the Board of Trade, on the subject of light railways, should lead to serious consideration of the necessities of many country districts. As pioneers in the construction of light steam tramway locomotives, we should like to point out the advantages of steam tramways in districts now inadequately provided with railways for carrying passengers and produce to the trunk lines. Such tramways or light railways could be made at low cost, ordinary railway metals and sleepers being used, and the rolling stock would be about one-tenth the weight and cost of that used on main lines, while the speed need not exceed eight to fifteen miles per hour. Under such conditions, using covered-in tramway locomotives, there should be no objection to the lines being laid alongside country roads and through fields, there being practically no danger to ordinary road traffic. Such a line has been at work at Wantage since 1872, as a feeder to the Great Western Railway, carrying both goods and passengers. MERRYWEATHER AND SONS.

Greenwich, November 13th.

## COAL MINING EXPLOSIVES.

SIR,—Certain experiments with a German explosive named "Westfalite" were held near Wigan on the 24th ultimo, and reports of the results, signed by a committee, were published in THE ENGINEER and several other journals. The reports were accompanied by certain statements regarding Westfalite, which were no doubt based on information furnished by the syndicate which is endeavouring to introduce the explosive.

In order that your readers may form an opinion as to the accuracy of these statements, and the value of these experiments, I would ask you to be so good as to print the following paragraphs in parallel columns:—

| | |
|---|---|
| 1. Press Report. — "The Government of Saxony, who for many years prohibited the use of any kind of explosives on account of the dangerous nature of the Saxon coal mines, have made one exception in favour of Westfalite, and its use is now authorised in all coal mines in Saxony." | 1. Extract from letter from the Royal Saxon Mines Department, dated November 3rd, 1894:—"The use of explosives in the coal mines of Saxony is *not* prohibited. The explosive Westfalite has up to the present only been used *experimentally* in Saxony." |
| 2. Press Report.—"This new explosive — 'Westfalite' — has been the first to be allowed on the continental railways as ordinary cargo." | 2. German Railway Regulations for 1894, Anlage B, paragraph XXXVI., *c*—abbreviated—"Dahmenite and Westfalite are carried in tin-lined wooden cases containing 50 kilogrammes, marked and certified as to their contents." This regulation is a repetition of XXXVI., *b*, which refers to roburite, and has been in force for years. |
| 3. Committee's Report.—"No. 8 shot—16½ oz. carbonite, half cubic foot coal dust, without gas. No flame, no explosion. No. 1 shot—16½ oz. carbonite, half cubic foot coal dust, and 5 per cent. coal gas. No flame, no explosion." | 3. Report of experiments carried out by the Westfalite Company, at Sinsen, in Germany. on May 29th, 1893:—"No. 2, coal carbonite 178 grammes—less than 6 oz.—in 4 litres coal dust, without gas or benzine. Ignition, flame 15 metres long, strong charring." |
| 4. Committee's Report. — "Detonator used, No. 6 (Extract from programme, conditions of firing, paragraph 2. 'The detonator of each shot to be of the same number')." | 4. Pamphlet issued by the Westfalite Syndicate, p. 1:—"Westfalite can only be exploded with very strong detonating caps, charged with 1½ to 2 grammes of fulminate of mercury. Without these it is not an explosive." |

I would particularly draw the attention of the committee, Messrs. J. Burrows, D. H. F. Mathews, and Robert Isherwood, to paragraph 4. As they are no doubt aware, a No. 6 detonator contains only 1 gramme of fulminate of mercury. Either, therefore, the Westfalite Syndicate used a detonator which, by their own showing, was too weak to thoroughly detonate their explosive, in which case the safety tests were entirely illusory; *or* they used a detonator of a higher power, and thus violated the conditions which had been laid down by themselves, and which the committee supposed to be carried out.

H. A. KROHN,
Secretary,
The Roburite Explosives Company, Limited.
103, Cannon-street, London, E.C.

## ENGLISH AND AMERICAN LOCOMOTIVES IN SOUTH AMERICA.

SIR,—I think all who are interested—either scientifically or commercially—in the locomotive engine, must feel indebted to you for your timely article on "English and American Locomotives in the Argentine Republic," published in your issue of the 9th inst. The report of Messrs. Elordi and Esteves could perhaps scarcely fail to attract attention, in view, on the one hand, of the official position of its authors, and on the other hand, of the prompt and persistent means taken to give it the widest possible circulation. I do not mean to suggest that either of these factors ought in reality to have enhanced the document, or given it an importance beyond its mere intrinsic value, such as it is; and it is certain that, in the eyes of those competent by technical knowledge or by commercial instinct, to estimate its worth from the tone and character of its remarks, neither one or other of the two factors I have named could permanently raise it from the level of an unscientific and one-sided production, such as you have described it. In fact, it has been, I know, the frequent remark of men of sound judgment in such matters, that in their opinion both the matter of the report and the manner of its circulation partook too glaringly of a trade advertisement to warrant any serious importance being attached to it.

But I am aware that opinions differ on this point, and there is no doubt that whatever the original purpose and intention of its authors may have been in drawing up the document, it is clear that some parties, at all events, thought it would have an appreciable weight in certain quarters in influencing locomotive orders; otherwise they would hardly have gone to the expense of having it printed in pamphlet form, and sent broadcast over the globe, as I can testify to its having been sent, from information reaching me from friends in widely distant quarters of the world.

Who these are who have been distributing the pamphlet it is perhaps not difficult to imagine, although to suggest here the American locomotive makers whose name occurs to one in this connection would be unkind. At all events, it is not, I presume, the Argentine Government, for it is scarcely to be supposed that they would feel justified in spending public money in distributing it, either in the interest of science or in pushing the trade of North American locomotive builders. Nor can it be supposed that Messrs. Elordi and Esteves are so proud of their handiwork as to spend their private means lavishly for the sake of giving their offspring a world-wide circulation, because, on reflection, they must be keenly alive to the fact that their inability to distinguish between tractive power and adhesion—as exemplified in the sentence you quote, viz., "The high-pressure, 160 lb. per square inch, at which the boiler is worked, becomes necessary to overcome somewhat the lack of adhesion"—is not calculated to raise their scientific or technical reputation in the eyes of the engineering world.

So far as the English locomotive builders specially named in the report—and whose locomotives came under the dire condemnation of the authors—are concerned, I should imagine they need concern themselves but little about the matter, as judging from all I hear about the manner in which their reputation is established at home and abroad, I fancy it will take something weightier than anything Messrs. Elordi and Esteves have indicted to shake the confidence of railway men in the competence of the firm; and that this view of it is shared by the firm in question may be judged from the dignified silence they have maintained on the subject under considerable provocation.

But seeing that the American engineering press thought proper to give the report a place in their pages with laudatory comments—as though, forsooth, it were the work of some past-masters of science or of high-class locomotive experience—it seems only right in the interests of fair-play as between English and American locomotive makers, as well as in the interests of truth itself, that the occasion should be taken to criticise and dissect this remarkable document collaborated by Messrs. Elordi and Esteves.

It is to be hoped, therefore, that those who are in a position to do so will throw light on the subject. Mr. Gould is in the best of all positions to enlighten us, and I trust he may see his way to respond to your invitation. It must be remembered, however, that his official position may render it difficult for him, as one can well understand, to enter into the controversy. The Buenos Ayres Great Southern Railway Company has, as is well known, to approach the Argentine Government for concessions from time to time, for the extension or improvement of its railways; and assuming the company to be contented with the design and quality of its rolling stock as supplied to it by English makers—as we have every reason to assume it to be from the fact of its having again and again repeated it — the probability is that the railway company may regard Messrs. Elordi and Esteves' preference for American rolling stock as no concern of theirs, and continue to remain quiescent, leaving to Messrs. Elordi and Esteves a bloodless victory of words—"of sound and fury signifying nothing."

In fact, it is not improbable that it was the knowledge of this bar to a crushing rejoinder from the Buenos Ayres Great Southern Railway Company that led to what I may call the dimming of Messrs. Elordi and Esteves' official spectacles, and to the consequent one-sided treatment of the subject so characteristic of their report.

Time does not permit of my going more at length into the subject now, but, with your permission, I may have something further to say hereon on a subsequent occasion.

Manchester, Nov. 13th. VERITAS.

## THE PRESSURE OF GASES.

SIR,—When any two gases exist in a closed vessel, each exerts the same pressure as if the other was not present. Thus we might have a mixture of hydrogen and carbonic acid gas, in which the pressure of the hydrogen was 100 lb. on the square inch, and that of the carbonic acid gas 15 lb. on the square inch. Will any reader of THE ENGINEER who knows kindly tell me how this law was arrived at experimentally? I want to prove it to a class of students, but I do not know how. I cannot see how it is possible for the carbonic acid gas to have a less pressure than that of the hydrogen. I take it for granted that the total pressure will be 115 lb., and that the hydrogen will compress the carbonic acid to that pressure. How can the pressure of the two gases be measured separately? CLASS MAN.

November 13th.

# ASSOCIATION OF CEMENT MANUFACTURERS.

IN response to the circular issued by Messrs. Renshaw, Kekewich, and Smith, solicitors, of London, to which we referred last week, a meeting of cement manufacturers, which was largely attended, was held at the Cannon-street Hotel, on Monday last. An association was formed, and it was made a *sine quâ non* to membership that a statutory declaration in the following form should be made by the managing partner and resident manager of every firm desirous of joining the association:—

> I, &c. &c., do solemnly and sincerely declare that I am well acquainted with the practical manufacture of cement as carried on by the said firm or company, and that, according to the best of my knowledge, information, and belief, the said firm or company have not on any occasion during the last three years, or within my knowledge at any other time, brought to and added to the calcined product of the kiln, in passing through the crushers or mill stones or grinding machinery or any other subsequent process, a separate supply of raw Kentish rag stone, other stone, furnace or oven ashes, disused or exhausted fire bricks, or any other material, so that such added material would be ground, sifted or mixed together with the cement, and form part of the cement powder, and sent out, and sold the cement in this state. And I make this solemn declaration conscientiously believing the same to be true and by virtue of the Statutory Declarations Act, 1835.

The form of declaration was signed at once on behalf of several firms. It was clear from what passed at the meeting that adulteration on a much larger scale than was even supposed had been going on for some time at many factories.

SHEPHERD, HILL AND CO.—It is impossible, we think, to bear without regret that the contents of the Union Foundry Hunslet, Leeds, are to be sold by auction, the sale taking place on the 20th instant and following days. Probably no firm except Whitworth's has enjoyed a higher reputation than did Messrs. Shepherd, Hill and Co. for machine tools. Messrs. Wheatley Kirk, Price, and Goulty sell, be it observed, not only all the plant and tools, but the patterns, drawings, and designs of the firm, which practically means the goodwill of the business. The death of one of the principal partners a few years ago, followed lately by the sudden death of the acting manager, together with the age and increasing infirmity of the remaining partner, who has been ailing for some time, have been the main causes of the break-up. But this is not all. The last three years have been terribly bad for the machine tool trade. How bad the impending sale testifies. It is a deplorable fact that a firm which has supplied tools to the British and most of the foreign Governments, and our own railways, should have to succumb.

## CLEVELAND INSTITUTION OF ENGINEERS.

### BASIC OPEN-HEARTH STEEL FURNACES.

THE annual meeting was held at Middlesbrough on Monday evening, Mr. Charles J. Bagley—Moor Iron and Steel Works, Stockton—occupying the chair, owing to the illness of Mr. William Hawdon—Newport Ironworks, Middlesbrough—the retiring president. The Council reported that five members had been elected since last meeting.

The thirtieth annual report stated that six ordinary meetings had been held during the past year, and an excursion had been undertaken in the summer to the Middlesbrough and Stockton Corporations' Waterworks, in Baldersdale. There were 230 ordinary members of the Institution, five life members, and two honorary members—in all 237. All the retiring members of the Council had been re-elected, and Mr. F. H. Marshall—Ormsby Ironworks, Middlesbrough—had been elected a vice-president. Mr. Samuel Marston had been added to the Council. Mr. John E. Stead, Middlesbrough, had been elected president. The report was adopted, as was also the balance-sheet.

Mr. Bagley, in introducing the new President, said he was a man of world-wide reputation as an analytical chemist, and in accepting that position he conferred an honour on the Institution.

Mr. Stead, in taking the chair, said he was not that evening going to deliver an address, as he thought it would be better to give that at some other meeting, and Mr. Dawson's paper would take up the whole evening. He acknowledged the honour that had been conferred on him by his election as president, when he was not a trained engineer. As an excuse for accepting the position, he pleaded that chemistry, both theoretical and applied, was becoming more and more the useful handmaiden of the engineer, and it was very few engineering societies where the transactions did not show a good sprinkling of papers relating to chemistry applied to the arts and manufacture. He then called upon Mr. Bernard Dawson, of Malvern Link, to read his paper—of which the following is an abstract—on

### DIFFERENT TYPES OF BASIC OPEN-HEARTH STEEL FURNACES.

The author at the outset remarked that the Cleveland district owed both its past and present to the existence of the local iron ore. It would successfully compete with the West Coast of England in the production of pig iron from hematite ores, but the wisdom and policy were doubtful of continuing more and more to depend upon the importation of foreign ores. Were England to be involved in a war with countries which might easily interfere with the ready importation of hematite ores from abroad, the possibility of producing steel from Cleveland ores at a remunerative price would immediately receive considerable attention. Last year's production in the North of England of ordinary Cleveland pig iron was 1,338,043 tons, and of hematite, spiegel, and basic pig 1,336,141 tons. Deducting 260,000 tons from the latter as being basic pigs, this showed that Cleveland, with its unbounded supplies of native ores, had been making over 100,000 tons of hematite and spiegel iron entirely from ores derived from foreign sources, except perhaps a very small proportion from the West Coast, Ireland, or the Forest of Dean. Even if there were no fear of interference by a hostile foreign navy, Mr. Dawson asked whether it was not a questionable practice to comparatively ignore the local resources and seek for others afar off. To those local firms who had not only furnaces, but also ironstone mines in Cleveland, it would be worth while to think whether the most possible was being done to use these native ores. The excellencies and good qualities of basic steel had been freely admitted, and one had only to notice what the basic patents had done for Germany, to reflect whether Cleveland had benefited by them to the extent that might have been expected. In addition to British ores, there were many foreign ores available for basic working; among others the ores of Scandinavia.

The objection had been raised to the increase in the production of basic steel, that although in inland districts, such as Staffordshire, it might be possible to make basic steel where the cost of acid steel from foreign ores would be prohibitive, still the margin of difference in cost of production of a steel ingot from acid or basic materials upon the sea coast was a trifle if anything in favour of the steel made by the acid process from a hematite pig. That might be true at present, but it would be well to get particulars as to how they might best turn their attention to basic steel whenever circumstances might render it either compulsory or advisable so to do.

The author then called attention to the paper which Mr. H. H. Campbell recently read in Chicago on "Open Hearth Furnace Practice," which he said was most comprehensive and minute in its details, but devoted only a small portion to the basic side of the question, and to this branch of open hearth work he—Mr. Dawson—intended to confine himself in his present paper, to the exclusion of both ordinary acid working, and also what had been called the pseudo-basic processes, viz., those of adding lime to the charge in ordinary acid-lined furnaces, and also of melting hematite iron in the basic hearth. He would dwell chiefly upon the construction of the various furnaces in which successful basic working on the open hearth had been hitherto conducted.

In dealing with the types of basic open-hearth furnaces the author showed diagrams of a furnace of the Siemens type in use at Wärtsilä in Finland, which gave excellent results; also of a basic Siemens furnace at Ruhrort, which had comparatively flat arches to the regenerators; also of a furnace of novel design and construction at Witkowitz; also of a 10-ton furnace at Alexandrovsky Works. A diagram was exhibited of a furnace with Darby's patent basic backing—a layer of chrome ore and tar, magnesia and tar, or other carbonaceous and neutral refractory substances between the acid bricks and the metal casing.

It had been found at Brymbo that when the bricks were fluxed away, so that the layer of refractory material was reached, it had become so dense and hard that it would protect the metal casing for a sufficiently long period to considerably prolong the life of the furnace. The author showed diagrams of a 17-ton basic Siemens furnace designed by himself with a view to embody as many advantages and as few defects as might be of existing furnaces. Such a furnace had been in work for some months, and gave good results as regarded output, fuel consumption, and durability. A diagram was shown of a firebrick lining, forming a backing to the basic lining, carried right down to the bottom of the furnace. This provided for the weight of the crown being carried from the furnace bottom.

Mr. Dawson referred, at considerable length, to furnaces of the Batho type, with which, for purposes of comparison with the ordinary Siemens type, he included those of Messrs. Riley, Dick, Hilton, and Wailes. Among the advantages claimed for the Batho type of furnaces were less expense in excavations below normal ground line; weight of furnace proper and its charge not carried upon the arches of the regenerators; no danger of loss of metal through bottom of furnace into regenerators; workmen had not to stand upon plates heated by regenerators below; easy access to different parts, and consequent simplification of repairs; absence of danger from gas and air becoming mixed and burning in the vertical passages leading from regenerators to the "blocks" at each end of the furnace; the chequer work in the regenerators could be changed much more quickly and with less severe labour than in ordinary Siemens type regenerators.

It was mentioned that Mr. Riley had had a Batho furnace working for some years lined with his patent neutral lining between the acid shell and the basic—dolomite—lining. It had run usually 220 to 250 charges without any repairs other than those usual to the ends of the ports at the close of a week, and Mr. Duff's improvements for catching the droppings from the fluxed brickwork. Another improvement of Mr. Riley's had preserved the arches or crowns of the regenerators by preventing their injury by slag and dust. These had all proved very useful and of great value. The author then proceeded to show that the advantages claimed for the modifications of the Batho furnace were not so great, but he remarked that Mr. Dick's furnace and the Riley and Dick furnaces, which are on the Batho principle, gave satisfactory results, both as to time and cost of repairs, as well as convenience in working. With respect to the Hilton furnace, it would probably be found to embody the best features of the various Batho types of furnace, although it was perhaps a somewhat costly one to build. Some were of opinion that this furnace only required to be better known to be adopted, both for acid and basic working, inasmuch as the cost of maintenance per ton of steel made was only about a fifth of that of a furnace of the ordinary Siemens type. Some twelve of the Lash type of furnace had been in use at Pittsburg since 1887, of sizes varying from 15 tons to 40 tons capacity. That furnace worked quickly, was economical in labour, and was probably one of the most successful constructions of open hearth furnaces working in the United States. The best results had been obtained in that furnace with natural gas. A somewhat similar furnace was designed and patented by Mr. Thwaite some eighteen years ago. The Lash furnace proper was carried on rockers, and could be tilted by a hydraulic cylinder so that all or part of the charge could be poured out. The advantage of being able to tilt a furnace of that character was that a portion of the slag, which with all basic working was present in such large quantities, could be poured off during the working of the heat, and some economy of fuel would result, as slag being a bad conductor of heat, a thick layer of it would prevent the heat of the gas passing through the furnace being conducted as quickly into the bulk of metal as would otherwise be the case.

In treating on the sizes of furnaces, the author held that one of 20 to 25 tons was as large as would usually be found really economical, both as regarded labour and convenience of repairs. With very small furnaces, such as those of two to four tons capacity, the quantity of fuel per ton of steel cast was larger than in case of furnaces of 20 tons capacity.

Mr. Dawson then proceeded to discuss the question of materials used for building and lining basic furnaces. In England, the materials for the basic hearth and lower portion of side walls had usually been some form of limestone. In Germany dolomite bricks, but the use of magnesite bricks was extending. The Swedish practice would apparently be to use magnesite to the exclusion of anything else, were it not for the prohibitive price. Mr. Wailes had recommended the use of a lining of shrunk lime containing about 6 per cent. of small wire croppings, which were said to help to glaze the surface and bind the material together. As regarded the making of the bottom of the furnace there was indeed a multitude of counsellors. Calcined magnesite, dolomite and limestone had been used in German furnaces. Hearths of magnesite and anhydrous tar might be depended upon to give no trouble, and to last for 700 heats. The continental practice was largely that of burning in the hearth in layers, which were found to stand better than rammed ones as regarded magnesian hearths. Hearths so made might require gas in the furnace for forty to forty-eight hours to prepare them, and probably also required more care than was the case with a hearth the whole depth of which was rammed in at once. Very good work had been done in England, with magnesite, dolomite, and limestone.

The defects in the design of many open-hearth melting furnaces were referred to at considerable length. It was said that the rectangular bath or hearth of a furnace had taken the place of the circular or elliptical forms which had been tried with more or less success, both in basic and acid working, because if the outside of the furnace was circular or eilliptical, it became both awkward and expensive to brace and to tie, and if the rectangular form of the exterior were preserved, then a circular or elliptical interior meant so much less area of hearth than would be the case if the rectangular shape of the outside were adhered to with regard to the bath. Dealing with the methods of working, it was stated that no doubt a considerable time ought to be saved by pouring liquid pig iron into the open-hearth furnace, and it was to be hoped that some information would be forthcoming before long with regard to the continental practice carried out by a combination of basic Bessemer and basic open-hearth working, so that the obvious disadvantages of the present uncertainty as to the composition of the liquid metal and the extra waste and the wash and destruction of the hearth of the furnace, and also the cost of the extra plant and machinery involved, might be correctly ascertained. It was possible that a considerable reduction in the time occupied in the ordinary open-hearth basic process might possibly be made by the employment of Mr. Saniter's process to reduce the sulphur and the silicon in the charge; and that process might render it to a great extent unnecessary to require the owners of blast furnaces to make any special basic pig iron. It was admitted that the ordinary basic lining did not assist in the elimination of any great proportion of sulphur from the materials charged into the furnace. Thus it was natural to turn to Mr. Saniter's—or some other kindred process—for riddance from the finished steel of that objectionable element. Attention was called to Mr. Talbot's process for the preparation of molten pig iron for the open-hearth furnace, and to Mr. Darby's re-carburisation process. A long and interesting discussion took place on this important paper, a report of which is held over till our next issue.

---

NAVAL ENGINEER APPOINTMENTS.—The following appointments were made at the Admiralty:—Staff engineer: Charles W. Thorne, to the Abyssinia, to date November 9th. Chief engineer: Thomas C. E. Hughes, to the Indefatigable, to date November 9th. Engineers: W. R. Apps to the Bruiser, and William Onyon to the Dasher, to date November 14th; M. Sennett, to the Speedwell, Edward G. Guyatt, to the Plassy, T. H. Hutchings, to the Lapwing, and William W. Pearce, to the Rambler, to date November 9th. Assistant Engineers: W. E. Townsend, to the Devastation, and Owen A. Morris, to the Speedy, to date November 9th.

THE INSTITUTION OF CIVIL ENGINEERS.—On Tuesday evening Sir Robt. Rawlinson, K.C.B., delivered a short address, as president. He referred to the rebuilding of the greater part of the Institution House now taking place after nearly fifty years, and he then traced the growth of engineering works from 1610 to the present time. "Of all the branches of civil engineering, no more remarkable progress has been made during the last half-century in any one department than in that which is concerned with the health and personal well-being of mankind. Sanitary science is, in a sense, as old as civilisation, but it may puzzle a lexicographer to give a satisfactory definition of it. Sanitary science does not necessarily meddle with medicine, nor with surgery, but bases its results on scavenging, town sewering, house-draining, and on insisting upon all means for domestic and personal cleanliness. Among the principal of the improvements brought about by the progress of sanitary science, after main-sewering, house-draining, water supply and scavenging, have been the establishment of public baths, wash-houses, and disinfecting apparatus. Some of these establishments have, however, been too grand and costly, as also placed too remote from the poor, and have consequently been failures. It has become usual to credit sanitary works, such as sewerage, drainage, and improved supplies of water, with the observed reduction of deaths in the district; and I know that good sanitary works do tend to promote comfort, to prevent sickness, and to prolong life. In 1846 I proposed the area of North Wales as a source from which to draw water for Liverpool and Manchester, and subsequently for Birmingham. The scheme at that time was thought to be too costly. Liverpool now draws water from the head of the river Severn; Manchester brings, for a distance of ninety miles, water from Lake Thirlmere. Glasgow is provided with water from Loch Katrine. Birmingham will presently be supplied from the hills of Radnorshire. The supply of water to London is still derived mainly from open rivers, the Thames and the Lea."

---

## LIEUTENANT-COLONEL BARKER ON EXPLOSIVES.

ON the evening of Saturday week, at a meeting of the Birmingham Association of Mechanical Engineers, Lieutenant-Colonel Barker, honorary member, superintendent of the Royal Small-arms Factory, Sparkbrook, and formerly assistant superintendent at the Royal Gunpowder Manufactory, Waltham Abbey, read a paper on "Explosives under Control." Mr. E. Hazel, president, was in the chair, and among those present were Colonel Cameron, commanding the district; Dr. Drury, and Messrs. S. B. Allport, Proofmaster; J. Mills, A. Fairley, Hands, C. Sendey, W. H. Bushill, A. Driver, H. Garbutt, J. Cox, W. Deakin, L. O'Brien, secretary, &c.

Lieutenant-Colonel Barker said that the energies of mechanical or civil engineers are nearly always devoted to efforts of construction. "They, as you are well aware, usually leave demolition and destruction to their military brothers. Civil and mechanical engineers are content to overcome difficulties which Nature presents by the exercise of mechanical skill, scientific arrangement of forces, and patient and untiring energy. We, on the other hand, of the military profession, are often forced to adopt rougher and more expeditious methods, when we see Nature's laws and scientific skill arrayed on the side of our enemies. We, I say, have to bring to bear in a more violent manner the greatest forces which are known to science, either to destroy combinations of mechanical and engineering skill united against us, or so to array our own forces that any possible enemies may understand and remember that "Though we are not splenetic and rash, yet have we something in us dangerous, which let their wisdom fear." Hence, gentlemen, I do not propose to deal generally with explosives—either as regards their manufacture or their characteristics—as merely uncontrolled destructive agents, but to discuss their properties this evening chiefly as motive forces of the highest order, and I have, therefore, adopted as the title of this paper, "Explosives under Control." All of us are too well acquainted with explosives not under control to need more than a passing reference to them in this lecture. Our old friend steam, even in the present day, occasionally breaks loose, as so frequently happened in the infancy of its use, and plays havoc with those who do not hold the reins with sufficient care, or who overlook or neglect the precautions which its employment demands. The ruined engine house or blown-up boiler tells its own tale of control for the moment lost of our best known motive force. Again, coal-gas is a good servant, but a bad master, either in domestic use, with engines, or in mines. So we might go through the list until we arrive at what the general public only recognise under the title of explosives, namely, the group of propellants derived from gunpowder, gun-cotton, nitro-glycerine, tri-nitro phenol, or picric acid, and kindred compounds. I propose, therefore, to devote the time at our disposal this evening to the consideration of these explosives from the point of view indicated in the beginning of this lecture. Gunpowder, from even a recent point of view, was looked upon as a violent and uncertain explosive, which when used in guns of great strength would send a shot through the air with tremendous but unknown speed. It was also credited with the propensity for blowing everything to pieces. The new propellant modern gunpowder was regular in its action, capable of complete control, and achieved results which compared favourably with those of steam." Having ignited a grain of "S.B.C." powder—9600 of which go to a charge for one of our big guns—in order that the audience might see for themselves that the powder was not very violent in its action, the lecturer said that this gunpowder nevertheless, in a charge of 960 lb., would send a projectile nearly a ton weight through space at rates of over 1300 miles an hour, the speed being calculated to a foot, and regulated with as much care and as little variation as that of a railway express. Having explained by means of tables the conditions which must be fulfilled by gunpowders before they can be accepted for the British service, and the methods employed in a powder factory to obtain regularity of results, the lecturer referred to an interesting result obtained since the new breech-loading guns and brown powders were introduced, when a 9 2in. gun was fired at a high angle of elevation. If they could imagine the highest mountain in Europe, Mont Blanc, placed between Birmingham and Wolverhampton, a shot which was fired not very long ago would, if discharged from the former place, have passed 5482ft. above the summit of the mountain, and lodged at the other side in Wolverhampton. This gave some idea of what modern guns with modern gunpowder would accomplish. They could not yet say what would be done when smokeless powder was further developed. This result suggested that we might possibly enable a projectile to leave the earth, as suggested in one of Jules Verne's stories; but practical gunnery had not yet approached to this. A velocity of between five or six miles a second would be required for the purpose, while about 4980ft. per second was our present maximum. Possibly in the next few years we might succeed, and attempt to disturb the equilibrium of the planetary system by sending messengers to the moon or elsewhere. The still more modern propellants or explosives under control had nearly all been evolved from what were usually called "high explosives," of which gun-cotton, nitro-glycerine, and picric acid were the types. These "high explosives" developed enormous pressure, and were intensely violent and uncertain in their action, and until very recent years they were considered quite out of the range of control, and all efforts to use them as propellants met with but scant success. Messrs. Nobel and Co., however, discovered some years ago that a union of nitro-glycerine and nitro-cellulose—gun-cotton—produced a compound which was under control and capable of marvellous developments for propelling purposes. Just as unions—matrimonial or otherwise—in human affairs frequently tamed down turbulent individuality of disposition—so these two chemical compounds and violent explosives had submitted themselves when combined to an existence of quiet discipline and useful co-operation. These two most violent explosives, developing when ignited separately instantaneous pressures of 150 tons or more per square inch, and destroying everything in the vicinity, became, when united in the proportions of 58 of nitro-glycerine and 37 gun-cotton, with 5 per cent. of mineral jelly, valuable members of the propellant community. Having shown by experiment the safety of the new combination—"cordite"—by burning it and by striking it violently with a hammer without any explosive results, the lecturer mentioned an experiment carried out a few weeks ago at Shoeburyness with a 12in. breech-loading gun and smokeless powder. Three shots were fired at a target at 2000 yards, and all three projectiles passed through the same hole in the target—equal to sending three bullets of nearly an inch diameter in succession through a hole the size of a shilling at 400ft. distant. If sufficient steam pressure could be developed to give a similar velocity to the shot, it would take a very well regulated set of valves and a very careful engineer to turn them on and off, to obtain results of such accuracy. With regard to the risks attending the manufacture of these new propellants, it must be admitted that even "explosives under control" were, in the early stages of their manufacture, attended with considerable risk, as they had been too frequently reminded during the present year. Those who, like himself, had for years been associated with these substances fully realised the dangers involved, and were constantly alive to the necessity for the utmost precaution. But as the stages of manufacture proceeded the risk of explosion diminished, until in the finished prism of gunpowder, or the accepted unit of cordite or other smokeless propellant, were found substances which were very safe to handle, use, or store. The recent terrible explosion of nitro-glycerine at Waltham Abbey, close to buildings containing tons of the smokeless powder, cordite, none of which was in the least affected by the explosion—though the buildings containing it were wrecked—was only a further proof of the stability of the new compound. Having shown photographs recently taken at Waltham Abbey as examples of what explosives can do when they escape from control, Colonel Barker said that the keeping qualities of modern gunpowder and service propellants were pretty well assured now cordite had been subjected to the Arctic cold of a Canadian winter and to severe tests in the tropics, and had stood each ordeal well, and he had while at Waltham Abbey exceptional opportunities for observing and noting the perfect keeping qualities of cordite when exposed to a high temperature in a closed building, and also to all the vicissitudes of an English climate in an open doorway. There were many other smokeless propellants whose claims had been brought before the public, but the most promising and successful ones consisted either of mixtures of gun-cotton and nitro-glycerine or of a nitro-compound of the gun-cotton type by itself. Comparing the results of steam with those of gunpowder and its kindred explosives, the lecturer said that when one stood on a railway platform and saw an express train rush past at sixty miles an hour, it was difficult to avoid a feeling of amazement at the rapidity of its movement and the propelling power which drove it. Keeping this example in view, they could better realise the significance of the velocities recently attained, and which represented velocities of over 2700 miles an hour. Lord Armstrong mentioned last month a velocity achieved of 4980ft. per second. Before an express train going at full speed from Birmingham could reach London a shot travelling at the rate now accomplished would pass beyond the North Pole, or if travelling towards America could announce its presence in New York before the train arrived at Northampton. Again, the working pressure of steam generally ranged between 30 lb. and 250 lb. per square inch, while the working pressures of the new propellants ranged from about 35,000 lb. to 40,000 lb. But though these high pressures were essential for artillery purposes, they were capable of almost unlimited reduction, if required, by various expedients—air-spacing, use of water, &c.—which could be adopted. As to the possibilities of the application of "explosives under control" to peaceful uses, this had long been dreamt of, and had been attempted on various occasions unsuccessfully with gunpowder. There were, however two insuperable objections to the old explosive in this connection. First, it only developed during its combustion about 280 volumes of permanent gases; secondly, the solid residues of explosion were very considerable, and would soon clog any machine. At the same time, it should be remembered that 1 lb. of gunpowder was capable of developing about 170,280 foot-pounds of energy. The recent discoveries of smokeless powders, however, had placed at our disposal a new material capable of developing still higher energy, also more under control, and giving off about 1000 volumes of permanent gases against the 280 of gunpowder, while it left no solid residue. The temperatures developed by all these propellants were high; but it was very possible that this difficulty could be obviated by invoking the aid of water, which, during its conversion into steam, would utilise, render latent, or absorb much of the excessive heat. Water in this way might be able to render its valuable assistance as an older or more trusted servant, taming and bringing under discipline its more youthful companion. "It may be well now to recapitulate some of the results of recent experience and research as to the quantity of heat and volume of gases per gram, and energy per pound developed by our modern propellants. The results which I now quote were only published a few weeks ago in the "Proceedings" of the Royal United Service Institution.*

| Name of explosive. | | Calories per gram. | Total volume of gases at 0 deg. C. and 760 mm. c. c. per gram. |
|---|---|---|---|
| Gunpowder | | 720 | 280 per cubic inch. |
| E. C. | English | 800 | 574 ,, |
| S. S.<br>Sporting powder | English | 790 | 734 ,, |
| Cordite, English | | 1250 | 882 ,, |
| Ballistite, German | | 1291 | 822 ,, |

Note:—1 Calorie = 2·2 thermal units.

The temperature of gunpowder on explosion is about 4000 Fah. (2200 C.), and that of the smokeless powders is believed to be considerably higher, though not as yet fully determined. The calculated energy of gunpowder per pound is 76·02 foot-tons, or 170,284 foot-pounds; while if infinitely expanded—or in a gun of infinite length—the theoretical work = 486 foot-tons per pound. Also a 100 lb. shot from a 6in. gun has recently developed—with 3000ft. muzzle velocity—an energy of 5884 foot-tons. Further, the actual muzzle energy developed in the projectile—1800 lb.—of the 111-ton gun is 5523 foot-tons, or over 123 million foot-pounds, and the projectile will pass through 32in. of wrought iron at 1000 yards. I submit, therefore, that these results give some idea of the stupendous forces placed at our disposal by the introduction of modern propellants. Energy of a railway train of 100 tons going at 60 miles an hour = 12,100 foot-tons. Theoretical work obtainable from 1 lb. coal = 4980 foot-tons. A "powder engine" was already in existence, called the American ram, for pile driving, and worked with surprising efficiency. This, of course, was a very primitive engine; but so also were those which first brought steam and electricity into use. When they compared the early attempts of their illustrious countryman, James Watt, in the use of steam with a present-day marine engine, or a new railway locomotive, it could hardly be said that a new and better use for "explosives under control" was altogether outside the range of practical possibilities. These suggestions may or may not be of interest to those present, and may possibly provoke a smile. I cannot, however, forget that I am addressing an audience whose professional ancestors have made fire and steam their most useful servants, and whose scientific brethren have tamed and utilised the lightning flash of electricity, and recognised and developed the motive power contained in the loadstone and the magnet. I feel, therefore, that this aspect of the subject, "Explosives under Control," could not well be brought before an assembly more capable of considering and of developing the idea in a practical form, if they desired to do so, than the Mechanical Engineers who have listened so kindly to the paper which I have had the honour of reading this evening."

A discussion took place, in the course of which some practical questions were asked. The President, on the question of gunpowder engines, pointed out that the fusibility of metals, the effect of the enormous expansion on valves, joints, &c., were among the difficulties to be overcome. Lieutenant-Colonel Barker, replying to Mr. Allport, agreed in the probable correctness of the theory that in the case of certain cartridges the effect of the unusually large cap in driving the projectile forward a few inches before the powder was fairly ignited might account for the reduction of the breech-pressure 40 per cent., which was claimed as one of the advantages of the powder. As the Thunderer investigation proved, the old story as to "ramming home" being a preventive of bursting was incorrect. Indeed, it had been demonstrated that the diminution of pressure on the barrel was in a direct and calculable ratio to the air space.

On the motion of Mr. Driver, seconded by Mr. Deakin, and supported by Mr. Allport, a hearty vote of thanks was given to Lieutenant-Colonel Barker for his paper.

## LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.

THE usual monthly meeting of this Association was held in the K room of the Cannon-street Hotel, on Saturday, the 3rd inst., at 7 p.m., when the president, Mr. Wm. H. Bale, occupied the chair, and the vice-president, Mr. R. J. Cook, was in the vice-chair.

After the conclusion of the general business a paper was read by Mr. Andrew King on "Drilling Square and Angular Holes." Mr. King said a machine had been patented in 1888 for drilling square holes, and improvements on it introduced and patented in 1890 which greatly increased its usefulness and enabled them to drill holes of almost any shape and any number of sides over three. The first machine worked on the principle that if a triangular spindle rotates in a square hole some point in the spindle will describe a square, and if an equilateral triangle rotates so that one of its angles is always in contact with the sides of the square, then that angle will describe a square. Instead of a triangular spindle a round one with triangular cams on is more convenient in practice, and as the sharp corners of the triangles would soon wear, the outlines of the cams is a combination of circular arcs which rotate smoothly within a square die plate. To determine the outline of the cams an equilateral triangle is described with sides equal to the sides of the square required. From each corner of the triangle, with a radius equal to half the length of a side, describe arcs outside these corners; then from each corner, with a radius equal to one and a-half sides, describe arcs, joining those previously drawn to complete the outline of the cam, and on this a circumscribing square is formed to represent the die plates. The tool used with this machine was triangular in section, and set with the cutting edge in line with the apex of the originating triangle. With this arrangement it was difficult to produce square holes with perfectly flat sides and sharp corners; and as cams and dies had to be provided for each size of hole, it was not well suited for general use.

The latest improved machines work on the copying principle, by which, if a roller is moved round a die with its surface in contact with it, its centre will describe a figure of similar shape, but smaller in size than the die. The drilling spindle is held by and revolves in a ball-bearing placed somewhere in the middle of its length, the top end being controlled by the roller and die plate, while the drilling tool oscillates as it revolves, the cutting point describing a figure similar in shape to the die at the top, but smaller or larger in proportion as the ball-bearing is below or above the centre of the spindle. The tool used with this arrangement is triangular in section, and shaped to clear itself when turning in the corners, and the cutting edge must be exactly in the centre of the spindle when holes with flat sides are produced, but convex or concave sides can be produced as desired by setting the tool a little on either side of the centre of the spindle. The size of the holes is varied by altering the distance between the ball-bearing and the cutting edge of the tool by using a conical roller at the top end of the spindle and varying its height, or by using expanding dies and a spherical-edged roller on the top end of the spindle, the latter being the system more adopted on the best machines. Mr. King explained the details of the mechanism by which the various movements and adjustments were obtained, and said those machines were used successfully for such work as hoe spanners of different shapes and sizes, locking plates for locomotives, moulds for prismatic powder, torpedo work, &c. Several members expressed opinions on different details, and a hearty vote of thanks was awarded to Mr. King for his interesting paper.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Railway operating statistics.*—The annual report of the Rio Grande Western Railroad shows a reduction in operating expenses of 226,133 dols. accompanying reduced earnings of 395,000 dols. This reduction has been effected by the practice of economies without lowering the standard of the road bed or track, both of which are in excellent condition. With the restoration of business prosperity it is expected that the only important business in expenses will be in maintenance of rolling stock. Of paying freight there were hauled during the year 635,561 tons, a decline of only $4\frac{3}{4}$ per cent. from the previous year; but it was hauled an average distance of 164 miles, against 151 miles last year—so that the tonnage carried one mile shows an increase of 3 per cent. The average earnings per ton were 2·30 dols., against 2·56 dols. last year, and the average rate per ton per mile 1·405 cents, against 1·69 cents. An increased receipt of about one-fourth of a cent per ton per mile would have given as large freight earnings as last year. This reduction in average rate was not caused by competitive "cutting," or even chiefly by the carrying of any particular class of goods at a lower rate than the previous year, but mainly by the carriage of a larger proportion than usual of the cheaper classes of freight and of those which pass a longer distance over the line, and a much less proportion of general merchandise and other better paying freight. Of passengers there were hauled 213,540, a decline of $27\frac{1}{4}$ per cent. from the previous year. But the average distance travelled was 141·8 miles, as against 113·7 miles last year; and the average fare received was 2·44 dols. per passenger, as against 2·25 dols. last year, so that the decrease in passenger earnings was 21 per cent. The average rate per passenger per mile, however, was but 1·72, against 1·99 cents last year. This was due to a larger proportion of cheap-rate tours. The abridgment of passenger earnings proved to be more severe than was expected.

*Railway operating statistics, Louisville and Nashville Railway.*—The following table shows the results of operation on the 2956 miles of the great Louisville and Nashville system for the year ending June 30th, 1894:—

| | |
|---|---|
| Total mileage operated, L. and N.R.R. system | 2956 |
| Total mileage owned, controlled, and interested | 4831 |
| Gross earnings, dollars | 18,974,337 |
| Operating expenses (62·53 per cent), dollars | 11,863,785 |
| Net earnings from traffic (37·47 per cent.), dollars | 7,110,552 |
| Gross earnings per mile, dollars | 6419 |
| Operating expenses per mile, dollars | 4014 |
| Net earnings per mile, dollars | 2405 |
| Steel rails, miles | 2766 |
| Iron rails, miles | 167 |
| Locomotives | 568 |
| Cars in passenger service | 450 |
| Cars in freight service | 20,133 |
| Passengers carried | 5,152.130 |
| Passengers carried one mile | 192,098,210 |
| Fare received per passenger, cents | 85 |
| Passengers per train | 35 74 |
| Passengers per car | 10·42 |
| Distance travelled per passenger, miles | 36·10 |
| Rate per mile per passenger, cents | 2 35 |
| Net earnings per passenger train mile, cents | 35·91 |
| Freight carried, tons | 9,433,698 |
| Tons carried one mile | 1,398,679,019 |
| Rate per ton, cents | 71 |
| Rate per ton per mile, cents | 0 889 |
| Net earnings per train mile, cents | 54 944 |
| Cars per train | 19 14 |
| Tons of freight per train | 165 38 |
| Tons in each loaded car | 12 51 |
| Average haul per ton, miles | 79 |
| Earnings, per cent. of gross earnings— | |
| Passenger | 24·248 |
| Mail | 3·325 |
| Express | 2·191 |
| Train privileges | 0·150 |
| Freight | 67·993 |
| Rent of passenger cars | 0·132 |
| Rent of freight cars | 0·892 |
| Rent of engines | 0·504 |
| Rents | 0·380 |
| Car detentions, storage, &c. | 0·092 |
| Wharfage and storage, Pensacola | 0·049 |
| Bridge tolls | 0·006 |
| Telegraph | 0·022 |
| Storage, St. Louis | 0·006 |
| Total (gross earnings) | 100·000 |

*New York rapid transit.*—The engineer of the Rapid Transit Commission, who made a brief visit to Europe last summer, has made a report on some of the foreign systems of rapid transit, including the London underground railways—steam and electric—the Glasgow subway and underground railway, the Liverpool overhead railway, and the tunnel of the Sceaux Railway in Paris. His conclusions may be summarised as follows:—First, an underground railway operated by steam, even with the best mechanical ventilation, would be intolerable in New York. Second, a railway with a steady, frequent service can be worked successfully and economically by electricity. Third, an underground railway worked by electricity has a comfortable atmosphere, and in it great changes in temperature can be avoided. Fourth, the rail level should be kept close to the surface, as excavation from the surface is cheaper and safer than tunnelling. Fifth, if, however, conditions demand, a deep tunnel can be constructed, in which the circular form is best. Sixth, an underground railway can be so designed as to be attractive in appearance. Seventh, the work can be carried on through a busy street without endangering the houses, and without seriously impeding travel. New York is in great need of better facilities for handling city and suburban traffic, but the commission has been in existence for some years without having attained any decision.

*Tramway motors.*—While electric traction is coming into more and more extensive use for city, suburban, and country tramways, there is still a field for independent motors, but steam locomotives are not now very much used. The Mekarski compressed air system has been proved successful in many ways, but the objection has been the great weight of the engines. Improvements of importance have been introduced, by which the weight has been materially lessened, and the new motors are being given thorough tests in regular service. A superheated water machine is also being brought out, which is probably somewhat similar to the Lamm-Francq system in use in France.

*Tramway track.*—The growing tendency to a better and more permanent system of paving for city streets is leading to a more substantial system of track construction. At Terre-Haute, Ind., a 72 lb. flange rail is used—having a plain, ungrooved head—spiked to wooden sleepers 7in. by 5in. and 7ft. long, or bolted to corrugated steel sleepers 7ft. long, 7in. wide, and ½in. thick. The street is excavated to sub-grade—or formation level—and the earth compacted by a steam roller. A bed of concrete is then laid, and the track is then laid, the joints keyed up, and the line brought to correct surface and alignment. Concrete is then filled around the sleepers and under the rails, giving the rails a continuous bearing. When this has set a bed of sand is laid, and upon this the brick paving, a bevel-edge brick being used against the inside of the rail-head to form a groove for the wheel flanges. The joints are then thoroughly grouted.

*A city viaduct.*—At Cleveland, Ohio, a new steel viaduct 1542ft. long, connecting the high ground on each side of a flat valley, has recently been completed. There are fifteen truss spans of 56ft., separated by trestle towers 28ft. wide; an arch truss span of 168ft., one approach span of 72ft., and at the other end two approach spans of 42ft. In some of the towers the bottom panel of diagonal bracing at each side is replaced by plate arches, thus effectively connecting the columns, while at the same time affording easy access from adjoining property to a road which runs under the viaduct. The viaduct roadway is 29ft. 6in. wide, with a 12ft. sidewalk on each side. Trusses 28ft. long connect the ends of the 56ft. spans. Transversely between the tops of the columns are plate-girder floor beams 3ft. 6in. deep, while plate girder triangular brackets or cantilevers carry the sidewalks. The 3in. oak floor planking is carried by 12in. I-beams or rolled joists; except at the street railway tracks, where channel bars are used. Under each girder are two 12in. channels, back to back, with saddle pieces riveted between them, the rails resting upon oak blocks or longitudinals, resting upon the saddles. The truss arch is 168ft. span between end pins, and $55\frac{1}{2}$ft. rise. The lower chord or boom is curved. The upper chord is horizontal for 84ft., and then inclines down to the top of the end posts, which are $19\frac{1}{2}$ft. high above the skewback end pins. The structure is calculated for a moving load of 1000 lb. per square foot.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE iron market has recovered from the temporary relapse noted in last letter, and the position and prospects are both again more satisfactory. A furnace has been blown out at Tipton, but it is a question whether curtailment of production at a time like the present is not more of a benefit than an evil to the trade of the district as a whole. Pig iron prices are rather better, from 6d. to 9d. more than the figures mentioned last week being now generally asked.

In Midland iron trade circles conflicting reports have lately been current with reference to the manufacture of best iron until lately carried on by the New British Iron Company, of the Corngreaves Works. I have referred to this matter before. All doubt on the subject has now been set at rest by the issue this week by Messrs. N. Hingley and Sons, of the Netherton Ironworks, near Dudley, of a circular definitely announcing that they have become the sole proprietors of the registered trade marks and goodwill of the business lately carried on by the British Iron Company, at Corngreaves, including the well-known "Lion brands." Messrs. Hingley's works are in close proximity to those at Corngreaves, and their ironstone and coal mines adjoin and are of a similar kind. They are, therefore, in a position to make and supply "Lion" iron of the superior quality formerly produced. They will also continue at their works the manufacture of chain of that brand. Their works and machinery are of the most modern description, specially designed to produce iron of the highest quality and finish. The firm will use the "Lion" pig iron in the manufacture of "Lion" bar iron.

This special brand of pig iron will be made—along with other brands—by the Corngreaves Furnace Company, which is now the owner of the Corngreaves furnaces. As yet this last-named company has started only one of the furnaces under blast, but a second one will probably follow shortly. Depending upon the particular quality of iron which is being at the moment produced, I am informed that the output of each furnace will, as a rule, vary from 350 tons to 450 tons per week. The "Corngreaves" brand of cold-blast pig iron will be one of the qualities regularly produced in one of the furnaces. This is a brand, the excellence of which has long been known and appreciated in Staffordshire and other parts of the kingdom, whilst considerable quantities have for many years past been exported to most of the countries on the Continent. The "Lion" brand—referred to above—which will also be regularly produced, will not only continue to be the basis of Lion finished iron, but will continue to be used as a high-class foundry iron. It is the intention of the Corngreaves Furnace Company to make also commoner qualities both of foundry and forge pig.

Manufacturers doing business with Australia are glad to find that in the metal market in Sydney tin-plates are in brisk request, which is probably explainable by the circumstance that some very large contracts for tinned meat have been placed in that town for the supply of the Japanese army at the seat of war. Engineering and hardware stocks are low at Melbourne, and will require replenishing ere long, while galvanised sheets are in moderately good demand, and hoops are in fuller inquiry. The tone of business at Adelaide is reported fairly brisk. Sheep shears have been in request, for the wool trade has progressed since the passing of the American tariff admitting wool into the States duty free. The demand from the Australian goldfields for mining tools and machinery is satisfactory.

The railway wagon and carriage-building firms of Birmingham and neighbourhood are, I find from inquiries this week, only moderately engaged. The Oldbury Railway Carriage and Wagon Company, Oldbury, has just taken an order for one of the Indian railways, of which more information may be available for next letter. Brown, Marshall, and Co., are fairly occupied. The Metropolitan Railway Carriage and Wagon Company has no special work in hand calling for particular comment, and the same is true of the Midland Railway Carriage and Wagon Company.

---

* In the very interesting table quoted, compiled from researches carried out by Mr. W. Macnab, F.I.C., F.C.S., and Mr. E. Ristori, A.M.C., C.E., F.R.A.S., the gunpowder results were not included, as they had been previously recorded by Sir F. Abel, K.C.B., and Sir Andrew Noble, K.C.B., of Elswick.

The Birmingham Railway Carriage and Wagon Company, Smethwick, has lately been building dining saloons for South America, and other vehicles for the same country. It has otherwise been engaged principally upon English work.

The interests of the engineering and kindred trades of the district, as well as those of the numerous other industries which find a home in the Midlands, will, it is to be hoped, be served by the new Chamber of Arbitration, which was declared open by the Mayor of Birmingham a few days ago. The headquarters are at the offices of Mr. A. Addinsell, registrar of that city. The rules are somewhat similar to those of the London Chamber of Arbitration. Some two hundred gentlemen, experts in various trades, have consented to act as arbitrators if called upon. The Court expenses of one arbitrator and of chamber fees in a case of one hour's duration will be £2 2s.; for two hours, £3 3s.; and for three hours, £4 4s., with an addition of 10s. 6d. for each subsequent hour during the same day. In the case of the Tribunal of Commerce in Paris appeals are limited to amounts of over £60 in value. In the Birmingham case there is no limit. What seems strange is that the legal profession have given the matter their support. Anything which facilitates industrial peace is good for trade.

The prosperity of cycle engineering in the Midlands, as far as the domain of Humber and Co., of Beeston, Coventry, and Wolverhampton, is concerned, is evidently, as far as that concern can secure such a result, to be maintained. At this week's annual meeting, when the 12½ per cent. dividend mentioned last week was declared, it was announced that the company had found it necessary to protect its rights in France and in Spain, and was prepared also to spend money freely hereafter with the same object. The directors had not been able to recommend construction of works in the United States, but had arranged for the sale of the Humber rights, reserving certain powers over the management of the American company. Regarding the progress of this branch of manufacture as reflected in the experience of other firms, it is noteworthy that the Coventry Machinists Company has this week passed certain resolutions for reconstruction.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—A continued absence of improvement is still the general report, as regards the position of the engineering and iron trades of this district. The condition of the engineering industries is, however, no worse; if anything perhaps it is a shade better, and most of the works—with the exception of locomotive builders—are kept moderately employed, stationary engine builders being as a rule fairly off, and some of them busy; but there is still no move towards anything like general activity, and prices have to be cut very low to get hold of orders. In the iron trade the tone all through continues extremely dull, and no expectation is entertained of any real improvement until the turn of the year, or the commencement of next spring—makers and manufacturers in the meantime looking forward to a continued unsatisfactory business at unremunerative prices.

The Manchester Iron Exchange on Tuesday brought together about an average attendance, but there was again only a dragging sort of hand-to-mouth business doing. In pig iron buyers still give out orders only for very small quantities, and these are comparatively limited in number. For the most part makers' quotations remain nominally unchanged, but where there is any business to really test prices, a weakening tendency becomes evident. Lancashire makers, who are booking very little business of any weight, have had to give way slightly in their list rates for forge qualities, which are now being quoted at 39s., less 2½, at the works, with foundry qualities remaining at about 42s. For district brands makers' quotations remain about the same as those given last week; it can, however, scarcely be said that even at 38s. 6d. for Lincolnshire forge, delivered Manchester, orders of any moment are being secured, but there are moderate offers at about 6d. under this figure, which seems to be the buyers' idea of what forge qualities will have to come to. Foundry Lincolnshire remains at about 40s., and foundry Derbyshire ranges from 43s. 6d. and 44s. up to 45s., net cash, delivered Manchester. With regard to outside brands offering here, Middlesbrough is firm at about 44s. 4d. to 44s. 9d., net cash, for good foundry qualities delivered Manchester. Scotch iron is still quoted about 47s. 6d. for Eglinton, and about 50s. 6d. for Gartsherrie, net prompt cash, delivered at the Lancashire ports, but to get hold of business sellers in some instances would no doubt give way something on these figures.

Finished iron makers report no improvement whatever in their branch of trade, if anything the tone is perhaps rather quieter, with more eagerness to get hold of orders, owing to forges being kept only partially employed, and there is a considerable amount of underselling in the open market. Delivered Manchester or Liverpool, prices average £5 6s. 3d. to £5 7s. 6d. for Lancashire, up to £5 10s. for Staffordshire bars; £7 to £7 5s. for Lancashire and Staffordshire sheets, and £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths of hoops.

The steel trade continues quiet in all departments. For ordinary foundry hematites quotations remain at 52s. 6d., less 2½, and for ordinary basic billets £4 net cash, with steel bars offering at £6, and steel boiler plates £6 2s. 6d. to £6 5s. delivered in this district.

Business continues very slow in the metal market, with a weakening tendency, but list rates for manufactured goods so far remain unchanged.

The returns of the Engineering Trades Union Societies are, if anything, this month of a rather more satisfactory character, both the Amalgamated Society of Engineers and the Steam Engine Makers' Society showing a slight decrease in the number of unemployed members, and this is regarded as a specially encouraging feature, in that there should be even a small decrease in the number of unemployed members at a time of the year when the returns usually show an increase. The decrease, however, does not appreciably affect the general position, the Steam Engine Makers' Society having still about 5¼ per cent., and the Amalgamated Society of Engineers about 9 per cent. of the total membership in receipt of out-of-work benefit.

Representatives of the Lancashire engineering industries have come out pretty strongly this year as regards municipal honours. Sir Wm. H. Bailey, who has filled the Mayoralty of Salford with so much distinction during the past year, is succeeded in this office by another well-known engineer, Mr. Alderman Mottram, who for many years has occupied a prominent position in connection with the well-known firm of Messrs. Galloways, Manchester, and who is also a member of the Iron and Steel Institute of Great Britain, and throughout the whole of his career Mr. Mottram has devoted close attention to everything affecting the interests of the mechanical engineering profession to which he belongs. Bolton has, in Mr. Alderman B. A. Dobson, also elected a prominent engineer of the district to the office of mayor. Alderman Dobson is not only well known throughout the district by his close connection with the important firm of Messrs. Dobson and Barlow, the eminent machinists, who employ some 3700 hands, but he is perhaps quite as well known throughout the Continent of Europe, United States, Canada, Egypt, and India, and a few years back the French Government conferred upon him the Order of Chevalier of the Legion of Honour, in recognition of his valuable services to French industry. Mr. Dobson was also at the annual meeting of the Iron Trade Employers' Association, held in Manchester last July, elected, for the third year in succession, President of the Association. Another engineer, Mr. Alderman John Hall, of the firm of Messrs Robert Hall and Son, machinists and power loom makers, of Bury, has been elected to the office of mayor for that important industrial centre. Mr. Hall has been connected with the engineering trade throughout his business career, and is the head of the firm, which was established fifty years ago by four working men from the well-known engineering establishment of Messrs. Walker and Hacking, of Bury.

Mr. William Watts, F.G.S., the newly-elected president of the Manchester Geological Society, in his inaugural address delivered before the members at their meeting on Tuesday, dealt with "Waterworks Construction, and the use of Concrete and Earthwork in forming Embankments." Referring to the growing interest which had been taken in concrete embankments since the Vyrnwy dam was made, he remarked that when a new departure had been successfully introduced, ideas had a habit of becoming infectious, and might be adopted by others on the score of novelty, if for no other reason. He did not, however, think that concrete would ever entirely supersede earthwork for reservoir embankments in England, and as a substitute for earthwork concrete was not free from objection. The foundations must be increased, as the whole weight of the superstructure was confined to much narrower limits, and the centre of gravity was brought much nearer the factor of danger than in earthwork embankments made on modern principles. The use of concrete in the trenches below the surface of the ground was, however, an improvement on clay filled trenches, and he believed they were indebted to two Manchester engineers—Messrs. Bateman and Hill—for having recognised its advantages, and being the first to use it as a water-tight core in this class of work. There was another use to which it could be put, where it was superior to clay, in the use which could be made of it for pillars, to enable the refilling to proceed with one part whilst other parts were being excavated or refilled, which meant a saving in time, money, and timber.

The important question of the most suitable class of fittings for electric lighting installations was dealt with by Mr. H. A. Henderson, in a paper read before the Northern Society of Electrical Engineers, at their meeting in Manchester on Monday. During the course of his paper, Mr. Henderson expressed his opinion that the most satisfactory way of wiring was that which now commonly obtained in London, and had also been adopted by a few provincial contractors, viz., the distribution system, confined as far as possible to five ampère sub-circuits, each controlled by a double pole fuse; the advantage of this arrangement to consumers being considerable, as it allowed extra lights to be attached without much additional cost, providing, of course, the contractor had allowed for this in his mains. As to general fittings the use of good material was, of course, essential, but he feared that in these days of cheap continental rubbish this important point was often neglected, adding that at the present time there were continental firms who might be said to "run" English contractors. That was they got hold of a contractor who was short of capital and financed him by supplying him with inferior materials, mainly fittings, at a low price.

In the coal trade the position shows no improvement upon the very unsatisfactory outlook to which I referred last week. Supplies of all descriptions of fuel continue excessive, notwithstanding very few pits are working more than four days per week, and prices show a persistent weakening tendency. The better qualities of round coal still meet with only a very moderate demand for house-fire consumption, with prices cut very low to get rid of surplus quantities; best Wigan Arley can be readily bought at 10s. 6d. to 11s.; Pemberton 4ft. and seconds Arley, 9s. 6d. to 10s.; and common house coals, from 7s. 6d. to 8s. per ton. Steam and forge coals still meet with only a very slow demand, and inferior descriptions can be bought as low as 6s. 6d. to 7s. per ton at the pit. Engine fuel also continues a drug, with common Lancashire slack readily obtainable at 3s. 6d. to 4s., and best qualities quoted 5s. to 5s. 6d. at the pit; whilst common slack from other districts is offering at 1s. 6d. to 2s. per ton at the pit mouth.

In the shipping trade only a limited business is reported, with common round coal obtainable from 8s. and 8s. 6d. up to 9s. per ton, according to quality, delivered at the ports on the Mersey.

The Chatterley Whitefield Collieries are now being supplied with an extensive electric lighting installation, including arc and incandescent lighting. The work is being carried out by Messrs. J. P. Hall and Co., Oldham, who are also fitting out a large steamship for Messrs. Harland and Wolff.

*Barrow.*—There is no change to note in the demand for hematite pig iron. Business remains very quiet, and there are no indications of improvement from any quarter. On the contrary, there has been an increase in stocks in the Furness district, which, to say the least, is unsatisfactory; 6277 tons of pig iron have been added to warrant stocks at Barrow during the week, leaving stocks at 164,727 tons, or 70,104 tons increase since the beginning of the year. The explanation for this increase may probably be found in the fact that the steel works at Barrow were closed last week, and the output of the furnaces has probably gone into warrant stocks. Prices are easy at 43s. 5d., net cash, sellers; 43s. 4d. buyers. Makers still ask 44s. 6d. to 45s. 6d. for parcels of mixed Bessemer Nos., net, f.o.b.; 33 furnaces are in blast, as compared with 34 in the corresponding week of last year; 42 furnaces are standing idle.

Iron ore is still very depressed. Ordinary qualities are at 8s. 6d. and best at 13s. 6d. The local demand is very quiet, and the shipping demand is small.

Steel makers are in a rather more hopeful state. The order has been placed with the Barrow Steel Company for 5000 tons of steel ship-plates by Messrs. Hannay and Clarke, Barrow agents for Messrs. Neilson and Sons, Glasgow. Prices are easier for plates. There is a slow trade in ordinary rails, although some good orders are in the market, particularly on Indian States Railway account. The tin-plate bar trade is quiet, but is likely to revive. Very little is doing in billets, slabs, and wire rods. Shipbuilders are very busy, and are likely to be busier, as not only are they well off for orders, but others are expected. Marine engineers are well off for work, as also are boilermakers.

Coal and coke quiet at late rates, which are low.

Shipping is very quiet indeed. During the past week only 1970 tons of pig iron were shipped from West Coast ports, compared with 8281 tons in the corresponding week of last year, a decrease of 6311 tons. The shipments of steel were 4762 tons, compared with 12,120 tons in the corresponding week of last year, a decrease of 7358 tons. The aggregate shipments to date this year represent of pig iron 303,485 tons, and of steel 346,846 tons, comparing with 242,498 tons of pig iron and 416,630 tons of steel in the corresponding period of last year, an increase of 60,996 tons of pig iron, and a decrease of 69,784 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

Not much change has occurred in the South Yorkshire coalfield since last week. Trade is in a quiet condition, which is very unusual for this time of the year. The pits, on the whole, are working moderately; stocks, however, in some classes of fuel are rapidly increasing, and the good winter's business, which was anticipated during the early part of 1894, is rather doubtful of being realised now. The United States Tariff, it was expected, would stimulate the coal trade, by increasing the call for manufacturing sorts. This hope has been entirely disappointed. There are still a few minor disputes in the coalfield, but they are too unimportant to make much difference to business. House coal is not in such good request as it ought to be in November. The metropolis is taking a fair tonnage, but nothing like what the season trade ought to be. The usual winter advance, which was anticipated with the beginning of October, and again in November, does not seem to have been obtained; indeed, coalowners in this district find it hard to keep up summer prices, and in some cases it is reported that a decline of 6d. per ton has had to be conceded. The present quotations are as follows:—Silkstone make from 9s. 3d. to 11s. per ton; Barnsley House, 8s. 6d. to 9s. 6d.; other qualities from 7s. 9d. per ton upwards. In spite of the Hull returns exhibiting a large trade in export fuel from that port, business in steam coal is not so brisk—in fact, several "blocks" have been placed on local pits during the week. Railway companies are taking a fair tonnage, mostly on contract account, but from other sources the demand is reported as considerably weaker. Barnsley hards are up to 7s. 9d. to 8s. 3d. per ton; Parkgate and other sorts from 7s. upwards. Gas coal is having a good sale, and prices are steady at from 7s. to 8s. per ton. All sorts of small stuff are depressed. A good demand continues for manufacturing fuel, and prices range from 3s. 6d. to 5s. per ton. Smudge and small coal at 1s. 6d. to 2s. 6d. Coke remains unchanged at from 9s. to 11s.

In the heavy trades, reports this week are of a more cheerful nature. The large establishments engaged in the production of files, saws, and all kinds of tools are busily employed, and several firms are exceptionally pushed for deliveries. Some of the smaller firms are also well up in orders, although not so much pressed as the larger houses. A good demand is reported for stove grates, an industry which Sheffield shares largely with Rotherham. Orders are coming in freely for grates of the Louis pattern, which are highly ornamented stoves with graceful outlines. The general public have at last recognised the fact that there is abundant room for the exercise of artistic taste in this extensive branch of Sheffield industry. Some of the work sent out by our large establishments is extremely beautiful. Another design which is much sought after is the Stevens pattern, and the Adams festoon decoration is in greater favour. An improvement has also taken place in fenders. Bronze figures of an expensive description are a prominent feature of this trade. Placed on pedestals, or reclining at the corners of the fenders, they have a charming effect, and form a great addition to the decoration of the house. Most of the Sheffield establishments are busily engaged on stoves and fenders.

The rolling mills are now fairly well employed. Full time is in most cases being worked, which shows that the general business is looking up, the rolling mills being largely the key to most of the lighter trades. Boiler makers are also fully engaged, and the demand is growing every day.

In the lighter industries business is at present in better condition. Increased orders are reported to have come in from Brazil, Argentina, and Paraguay for cutlery. Since the change in the American tariffs there has not been any "boom," as was anticipated, but in its place we have had an ever-increasing trade, which has proved both more regular and useful to our manufacturers. Case goods for presents for Christmas and the New Year are in large request, and manufacturers are very busy on this account. A large quantity of inferior and cheap horn and bone, which has long lain idle in the warehouse, has been recently bought up for hafting purposes; fine and expensive ivory and other hafting material is not in such brisk demand—a sign that the Americans are neither buying nor making any considerable quantity of high-class goods. It is believed, however, that the American trade will assume large dimensions early next year. Silver and electro-platers are extremely busy on season orders, which are more numerous than usual. Sterling silver ware is in good demand, both for the home and foreign markets, the cheapness of silver having given a welcome impetus in this respect to the manufacturers. The progress of this important industry in Sheffield is proved by the number of cutlery establishments to which of late years this trade has been added. There are many novelties this year, the silver and electro-platers recognising more widely than ever that they must vary their designs and present fewer of the accustomed patterns season after season. Messrs. John Round and Son, Tudor Works, Sheffield, have just completed an admirable piece of artistic workmanship in the shape of a massive silver cup, the whole forming an excellent example of the silversmith's art. It was produced for the Liverpool Cup, is 33in. high, has a diameter at the widest part of 14in., and the total weight is 250 oz. Another noteworthy production is from the firm of Messrs. Walker and Hall, Howard-street. This consists of a wheelbarrow and spade, made to the order of the directors of the Manchester, Sheffield, and Lincolnshire Railway, for presentation to the Countess of Wharncliffe, on the occasion of the cutting of the first sod of the new line to London last Tuesday. The barrow, which is of polished English oak, elaborately carved, is decorated with a number of silver shields, which are richly engraved. The trundle, or wheel, has a sterling silver tire. The feet are made of solid silver, and the handles are mounted with silver. The barrow has a shield on each side bearing the arms and crests of the Earl of Wharncliffe and the railway company. The spade is also of oak, with a blade of solid silver.

The Board of Trade returns for October exhibit a decided increase in the exportation of hardware and cutlery. For the month the total value sent was £171,589, as compared with £167,949 for October of 1893, and £189,688 for October of 1892. The largest value was sent to Australasia, £22,778, an increase over that taken in 1893, but a large decline on the value sent in 1892. The United States, who occupy second place for the month, took a value of £19,962, an advance of £4000 on October of 1893, but £2000 less than in 1892. The increasing markets for this month are Germany, Brazil and Holland—which has jumped from £6947 to £15,602. The decreasing markets were Russia, Sweden and Norway, France, Spain and Canaries, Foreign West Indies, Chili, Argentine Republic, British Possessions in South Africa, British East Indies, and British North America. For the completed ten months of the year the total amount exported was £1,524,347, as compared with £1,729,389 for the corresponding period of 1893, and £1,822,666 for that of 1892. The largest value for the ten months was sent or Australasia, which country took hardware and cutlery to the amount of £200,421. Increases are reported for the ten month, from Russia, Sweden and Norway, Germany, Holland, Belgiums and Brazil. Decreases are shown by France, Spain and Canaries, United States, Foreign West Indies, Chili, Argentine Republic, British Possessions in South Africa, British Possessions in East Indies, Australasia, and British North America. In steel, unwrought, an advance is shown both on the total for the month and the ten months. The aggregate exported to foreign countries was £189,676 as compared with £128,414 for the same period of 1893, and £147,593 for October of 1892. Russia is the largest buyer this month with a total of £36,166. All countries except four—Holland, British East Indies, Australasia, and British North America—exhibit a satisfactory increase. For the ten months the total was £1,617,197, which is a material advance over the business of 1893 and 1892. For the ten months increases were also reported by all countries except Holland, United States, British East Indies, and British North America.

On Saturday night the workpeople of Messrs. Walker and Hall, Electro Works, Sheffield, to the number of 1500, were entertained at dinner by the Master and Mistress Cutler, Mr. and Mrs. C. H. Bingham. The workmen's dinner is usually held in the Cutlers' Hall; but owing to the large number employed by this firm, the Norfolk Drill Hall had to be engaged for the occasion. Advantage was taken of the dinner to present to the Master and Mistress Cutler a silver tea and coffee service and tray, together with an illuminated address. This is the third time the Master Cutlership has been held by members of the firm of Walker and Hall; the senior partner, Colonel J. E. Bingham, J.P., having worthily occupied the office for two years.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

Last week's improvement quickly disappeared, and traders gained little by it, because it affected pig iron alone, and only one quality of that. No doubt a good deal of business might have been done in that, but unfortunately the demand was for prompt delivery, and very few makers were in a position to sell No. 3 for delivery at once, seeing that their stock is almost cleared out; in fact, except during the Durham strike, it is many years since there was so little No. 3 unsold in makers' hands. Thus producers did not profit much by the spurt, and were able to sell very little iron at the advanced price; and the pressure to buy having gone off, the price has dropped back to the old rate, because second hands offer small lots at less, though neither they nor makers could supply large quantities. There is no disposition now to buy for forward delivery, and consumers are extra cautious after the spurt of last week. Still, taken as a whole, the amount of business doing this month is not so much as it was last month, and shipments are better than are usual in November.

The general price this week for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. pig iron has been 35s. 9d., or 3d. below the quotation of last week, but some producers are still getting 36s. for their brands. Most firms can secure 35s. 9d., but among merchants 35s. 7½d. was accepted early in the week for a few small lots. Cleveland warrants have been about 35s. 8d. cash. The quantity of Cleveland pig in Connals' warrant stores on Wednesday night was 88,698 tons, or 67 tons increase this month. No. 4 Cleveland foundry pig can be bought at 3d. less than was being taken last week, viz., at 34s. 9d., but grey forge has not fallen below 33s. 9d., a price which is said to be unprofitable. If it bore the same proportion to No. 3 as it usually does, grey forge should be realising 34s. 9d., but it is extra plentiful, while No. 3 is very scarce. Mottled iron is 33s. 6d. and white 33s. It may be stated that since re-opening their works after making a number of alterations and extensions, Messrs. Dorman, Long, and Co., of the Britannia and West Marsh Steel and Ironworks, Middlesbrough, have been using the commonest quality of Cleveland pig iron, viz., white iron, to make steel by the basic open hearth process, and they appear to have succeeded very well, as it is said that the steel produced has stood more severe tests than steel made from hematite by the acid process. This certainly is a new departure, and is of importance to the district. As the supply of white iron is very limited, if very considerable quantity should be required for use at the steel works, the price would quickly be enhanced. The old acid furnaces were employed in the experiments with a basic lining. The difference between the price of the white iron used and that generally employed for basic steel making is at least 3s. per ton, and that is a consideration in times like the present, when so little profit is to be made out of the business. The difference between the cost of basic steel and ordinary hematite steel might by the use of this cheaper pig be brought in favour of the former, and thus lead to the utilisation of more of our native ores, and reduce the importation of foreign ores.

The hematite pig iron trade is much depressed, and prices have touched figures that can leave no profits. Ore and coke are almost as dear to-day as they were when the price of hematite pig iron was 3s. per ton dearer, and as long as the production of the latter is kept up, materials are not likely to get cheaper. The output of hematite pig iron would seem to be in excess of the consumption, and if selling prices are to be maintained and cost of production reduced, it would apparently be the better policy to blow out some of the furnaces rather than turn them on to Cleveland iron, for the output of that is already more than equal to requirements. The quotation for M. Nos. of Cleveland hematite pig iron is 42s. 9d. per ton, with a few still asking 43s.

The Cleveland mine owners have had to refuse the claim of their men for a 5 per cent. advance of wages, for prices realised for pig iron have not improved materially since the last application was made. The men adopted new tactics to support their claim—they did not base their arguments as previously upon any advance in selling prices, for they would have had no ground to stand on there, but they wanted the advance because they said they were inadequately paid for the work they had to perform, considering the dangerous character of their employment, and the conditions under which such employment is carried on. Yet the conditions of their employment have not been altered for many years. To increase the cost of Cleveland iron ore at present will only tend to further limit its use, as it will make it more difficult to compete with the cheap foreign ores. The output of Cleveland ore, by reason of this competition, has been reduced over 30 per cent. during the last ten years.

All departments of the finished iron and steel industries are depressed, and manufacturers have brought prices down until they yield in many cases no profits; yet producers cannot meet with orders enough to keep their mills fully occupied. The bar trade is affected the least by the depression, and makers have been able to maintain their quotations at the same figures for a long time. Sheet does not compete much with iron in the bar trade, because consumers still prefer iron bars, for the reason that they are more readily welded. Common bars are quoted £4 17s. 6d., less 2½ per cent., f.o.t. Plates and angles are quoted the same prices for steel as for iron, ship plates being at £4 15s. and angles at £4 12s. 6d., less 2½ per cent. and f.o.t. Heavy steel rails are somewhat dearer nominally, but there is hardly any business done to fix prices. The quotation is £3 15s. net at works. Shipments of rails and railway materials have recently been better from the Tees, especially for India.

Ironfounders have probably never experienced a worse time than the present, and some do not produce more than a third the quantity of material they turned out in good times. Owing to depression of trade, Messrs. Sutherst and Southorn, Cleveland Steel Foundry, Guisbrough have had to cease operations. They have recently executed part of the steel castings for the eight cruisers building for the Admiralty at Chatham, Devonport, and Portsmouth, as well as for the Magnificent now building at Chatham. Bridge and wagon builders are fairly well off, but some of the locomotive shops are ill-supplied with work, as are also the general engineering works.

On Tuesday in the Council Chamber, Middlesbrough, in the presence of a numerous and distinguished company, including the Earl of Carlisle, Earl Grey, Sir James Kitson, Sir Raylton Dixon, Sir Matthew Gray, and Sir Joseph W. Pease, Bart., M.P., on behalf of the subscribers, presented a portrait in oils of Sir Lowthian Bell, Bart., F.R.S., to the Corporation, to be hung in the Council Chamber. This is the outcome of a movement set afoot early in the year by some of the principal traders in the Cleveland district to mark their appreciation of the eminent services Sir Lowthian had rendered to the various industries of the district, and the iron trade in particular. Subscriptions were received not only from the North of England, but from all other British iron-making districts, and also from the Continent and the United States, the total amount reaching £700. With this the committee were able to have not only a portrait for the Corporation, but also a replica for Sir Lowthian's family, and this was presented on Tuesday also. At the same time the mayor conferred the freedom of the borough upon Sir Lowthian and his eldest son, Mr. Hugh Bell, who has been for twenty-four years a member of the Council, for seventeen years as alderman. He was mayor in 1874, and again in 1883.

Among the new mayors in the North of England, Mr. Robert Redhead, the well-known shipbuilder, has been elected at South Shields; Mr. C. A. Head, of the Teesdale Iron and Engineering Works, at Thornaby-on-Tees; Mr. John Price, late general manager of Palmer's Shipbuilding and Iron Company, at Jarrow; Mr. William Haswell Stephenson, coalowner, &c., at Newcastle. The new Mayor of Stockton, Mr. Jonathan Samuel, was till within the last few years an ironworker.

The Durham coal trade continues very brisk, as is usual at this time of the year, when so much gas and house coal is required. In Northumberland, however, the best season is over with the close of the northern navigation, and some of the collieries have had to reduce their production, while prices generally are lower by 1s. 3d. per ton than they were a short time ago, best steam being now obtainable at 9s. 9d. per ton.

The directors of the North-Eastern Railway have decided to utilise their mineral branch from Cargo Fleet to Normanby for passenger traffic, merchandise, &c., and to extend the line to South Eston, provided they can obtain land for the extension on terms which appear to them reasonable.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been quiet this week. Scotch warrants were in moderate demand at about the closing rates of last week, with now and again a slightly easier tendency. The inquiry for Cleveland warrants has been dull, and only a small business took place in hematite warrants. The market does not possess any speculative interest at the moment.

Since last report four additional furnaces have been put in blast, and there are now 66 in operation, compared with 62 last week and 53 in the corresponding week of last year. Of the four additional furnaces lighted, three have been placed on hematite and one on ordinary.

The values of makers' special brands are fairly steady as follows:—G.M.B. f.o.b. at Glasgow, No. 1, 44s.; No. 3, 42s. 6d. per ton; Carnbroe, No. 1, 46s. 6d.; No. 3, 45s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1, 52s.; No. 3, 48s.; Calder, No. 1, 52s. 6d.; No. 3, 48s.; Summerlee, No. 1, 53s. 6d.; No. 3, 48s.; Coltness, No. 1, 55s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 51s. 6d.; No. 3, 47s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 58s.; No. 3, 50s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 5951 tons, compared with 5828 in the corresponding week. There was sent to Italy 357 tons, Germany 774, India 265, Canada 12, Australia 245, France 60, Holland 100, Belgium 40, Spain 45, China 218, other countries 1058, the coastwise shipments being 2777 tons against 1205 in the same week of 1893.

The manufactured iron and steel branches are dull, business generally coming short of what was anticipated at the end of the strike. Of steel a very considerable quantity is used daily in the shipyards, and this is likely to be maintained during the winter; for while some firms are slack, others have been obtaining new orders for vessels which will require fair quantities of raw material.

Locomotive engineers are in several cases busy with good prospects, but at the railway works there is less doing, the workmen in the Caledonian employment in Glasgow being on short time.

The coal trade keeps steady, the current output of the collieries being apparently fully absorbed. As a consequence of this, manufacturing consumers are having to pay higher prices than they expected, and some of the miners are endeavouring to get up a fresh movement in favour of an advance of wages. The coal shipments in the past week reached 151,397 tons, being 9437 tons more than in the preceding week, but still about 50,000 tons behind those in the corresponding week of last year.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE weather has again told seriously upon the coal trade, and I am assured that the storms of the week will total up a series of grave losses to colliery shipping.

Exchange news at Cardiff continues favourable to the outlook of the future, when better weather is experienced. For the present both prompt and forward business is dull, and the only satisfaction given is that prices remain tolerably firm. So far prices cling to 11s. for best steam. Last Cardiff figures are: Best steam coal, 11s. to 11s. 3d.; seconds, 10s. 3d. to 10s. 6d.; best Monmouthshire, 10s. 3d. to 10s. 6d.; small, 4s. 6d. to 5s.

There is only a moderate business going on in house coal, though the time is at hand for something more pronounced. Cardiff prices this week are:—Best households, 10s. 9d. to 11s.; No. 3 Rhondda, 10s. to 10s. 3d.; brush, 8s. 3d.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s. 3d. to 8s. 6d.; through, 6s. 3d. to 6s. 6d.; small, 4s. 6d. to 4s. 9d.

The coke market remains fairly active, but prices are unchanged, there having been a good deal of over-production of late. Patent fuel is selling at 10s. to 11s.; Swansea, 10s. 6d. to 11s.; Cardiff anthracite coal at Swansea is now quoted 8s. 9d. to 9s. for ordinary large, to 12s. to 12s. 6d. for best samples. Trade generally at Swansea has been affected by the violence of the weather. To this is due the exceptionally small export of tin-plates last week, only amounting to 23,380 boxes. The quantity received from the works totalled 70,155 boxes, and this naturally intensifies the situation, which is becoming critical.

Mid-week on 'Change, Swansea, the opinion was expressed in substantial quarters that unless an improvement should set in a general stoppage of works was inevitable. Perhaps this is taking too gloomy a view, yet mention was made at the meeting of several works that were preparing to close unless a change took place. It was also stated that the owners of these works thought that the expenses of keeping the works idle would be less than to keep on manufacturing plates at a loss.

A consideration of the tin-plate returns, just issued, should not strengthen existing depression, I submit. During the ten months ended October, 1893, 328,768 tons have been exported from Wales, the joint make of South Wales and Monmouthshire, and the value amounted to £4,336,882. During the same period this year the shipment was 283,763 tons, and the value £3,498,253. So if this shows a falling off, there are the improvements of October to fall back upon, showing an increase of 14,844 tons, and the value £153,592.

Very meagre returns come to hand in connection with the iron and steel trades, and the general dulness has been intensified of late by the depression in tin-plate.

Pig iron, too, is weaker. Swansea quotations this week: Glasgow warrants were down to 42s. 6½d., and Middlesbrough 35s. 10d. Other quotations were: Welsh bars, £5 2s. 6d.; sheet iron from £6; sheet steel from £6 5s. Steel rails, heavy, from £3 15s.; light from £4 10s. Bessemer and Siemens tin-plate bars from £4 to £4 2s. 6d. Bessemer tin-plates from 10s. to 10s. 3d.; Siemens, from 10s. 3d. to 10s. 6d.; ternes, 20s. to 24s.; and best charcoals, 12s. to 12s. 3d. Cardiff quotations are still lower than those of Swansea in some respects. Bessemer bars, for instance, are quoted at £3 18s. 6d. to £4; and Siemens best from £4 to £4 2s. 6d. This reduction is solely due to the lower figures quoted by the North of England.

Timber continues to droop. The latest quotations Cardiff, is from 14s. 10d. Iron ores are moderately inquired for, but at lower values; Rubio, best, selling at 11s. 1½d. to 11s. 3d. Cardiff; Tafna, 10s. 9d.; Garucha, 10s. 9d.; Porman, 10s. to 10s. 3d.

The agitation against the transfer of the Albion Fund to that of the Miners' Provident Fund continues. I am afraid this will tell against the expression of practical sympathy in the case of future calamities. At all events the public will be warned how to direct the disposition of their charities.

The Conway Waterworks are to be "inaugurated" this week. They have cost £40,000.

Arrangements, I am glad to note, have taken place between Captain Phillips and his employés, which have resulted in a concession of ten boxes per hundred until December 31st.

This will affect the works at Nantyglo, Blaina, Abertillery, Pontymister, and Waterloo.

The Cardiff Electric Works are to be opened on Saturday.

There is an impression that parliamentary business from the Cardiff district will be considerable next session. The Barry, it is understood, will make another attempt to obtain powers for tapping the Rhymney and other Monmouthshire valleys. The Bute Docks Company too will have an important Bill to promote, though of its nature little is known outside a small circle. The Taff and Rhymney Railways will also have Bills it is stated.

It is intended to double the line of the Brecon Railway between Pengam and Machen, a distance of about eight miles. This step is regarded as imperative on account of the marked increase in coal traffic over a good deal of the district in question. The opinion is current that an early start will be made next year, and that a large force of men will be put on to carry it out expeditiously.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE reports that come in from the different iron markets all bear a more or less unfavourable character. Instead of improving, iron business appears to become even more dull, and consumers as well as dealers are more than ever inclined to hold back with their orders; the state of both the raw and the finished iron trades is most discouraging. Of the Silesian iron business poor accounts are given in general. Makers of pig iron continue very weakly engaged, and there is no hope for increasing activity in that department until the demand for finished iron has improved. Extremely few orders are also forthcoming in the steel trade, and restrictions of output have already been reported in several instances.

Demand and sale continue fairly good on the Austro-Hungarian iron market, only for some articles of manufactured iron, such as bars and girders, a lessening inquiry has been noticed. The scarcity in pig iron, as well as the slight rise in quotations caused thereby, has led some dealers to order their supplies from foreign, especially English, firms, and large quantities of English pig iron, amounting to several hundred wagons in one case, are said to have been sold to an Hungarian works. The endeavours which German firms are constantly making to sell their products on the Austrian market have been successful of late, chiefly, no doubt, on account of the exceedingly low prices they quote.

In France the amount of business done on the raw and finished iron market is certainly not large, but fairly satisfactory. Prices continue low, as there are, on the whole, more offers than inquiries, and competition, especially that of Belgian works, is again rather disagreeably felt. In Paris merchant bars are at present being offered at 140 to 145f. p.t., and girders fetch 150 to 155f. p.t.

The tendency is to firmness on the Belgian iron market, and a pretty lively business is doing in most sorts of iron. Demand for home requirements is tolerably good, and foreign, especially transmarine orders, have likewise been more numerous lately. The Belgian State Railways have granted an order for 15,000 t. steel rails to Belgian works at the price of 119·90f. p. t., Krupp and the Bochumer Verein asking 124f. p.t. A Liége arms factory is reported to have booked a contract for 10,000 rifles and 1,000,000 cartridges for the Chinese Government.

It is as yet impossible to notice any change for the better in the Rhenish-Westphalian iron business. On the contrary, a tone of uncertainty and even depression is gaining ground. Iron ores are in limited request. The proposed convention of the Siegerland ore mines is expected to have a beneficial influence on the ore trade, particularly with regard to prices. Up to date, spathose iron ore is offered at M. 7·20 to 7·50 p.t. at mines, while roasted ditto fetches M. 10 p.t. Nassau red iron ore stands at M. 90 p.t., free Dillenburg, Luxemburg-Lorraine minette sells at M. 2·60 to 2·70, and 3·30 p.t. net at mines. A steady business is done in Spanish ores, though requirements are small generally; prices show no change whatever.

In the Siegerland the blast-furnace works are with but few exceptions in regular and some even in lively employment, a good amount of orders having been booked recently. In the Rhein and Ruhr district the physiognomy of the iron industry is less favourable; the dulness in demand continues, and there is no alteration perceptible with regard to quotations. Spiegeleisen, 10 to 12 p.c. grade, fetches M. 52 p.t.; Rhenish-Westphalian forge pig, No. 1 M. 46 to 47; No. 3, M. 40 p.t.; Siegerland, good forge quality, M. 44 p.t.; hematite, M. 63; foundry pig, No. 1, M. 63.; No. 3, M. 54, p.t.; basic, M. 45; German Bessemer, M. 49 to 50 p.t. Iron for making steel, M. 44 to 47 p.t. at works. Luxemburg forge pig is sold at 48f. p.t., free Luxemburg.

The outlook in the malleable iron trade continues anything but favourable. Bars and all sorts of sectional iron are in weak request, and only fetch very low prices. Hoops are rather brisk of sale, and heavy plates are also in tolerably good request, while sheets remain entirely neglected. Quotations for both plates and sheets have shown much weakness. The rivet business is also quiet just now. At the foundries and machine factories activity continues irregular, and altogether far from satisfactory; the wagon shops are generally in fair employment.

The following are the latest list quotations, per ton at works:—Good merchant bars, M. 102 to 105; angles, M. 120; girders, M. 90 to 95; billets in basic and Bessemer, M. 73 to 77; hoops, M. 108 to 113; heavy plates for boiler-making purposes, M. 150; tank ditto, M. 130 to 135; steel plates, M. 120 to 125; tank ditto, M. 120; sheets, M. 115 to 135; Siegen thin sheets, M. 125; iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivets, M. 145, in some instances M. 150; rivet iron, M. 130; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 110 to 120; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230.

In 1893 the output of the mines in Italy was, in tons, as under:—Iron ore, 191,305; maganese ore, 810; iron manganese ore, 8805; copper ore, 96,299; zinc ore, 132,767; lead ore, 29,004; silver ore, 1236; gold ore, 7393; antimony ore, 1193; quicksilver ore, 19,450; pyrite, 29,460; sulphurous ore, 417,671; mineral salt, 16,790; mineral coal, 317,249. The production of the blast furnace works, mills, and melting houses was, in tons:—Pig iron, 8038; bars, 138,046; cast iron, 8159; steel, 71,389; tin-plates, 2500; lead, 19,898; mercury, 273; antimony, 376; copper, 6911; zinc plates, 250. In silver 40,095 kilogs. were produced, and in gold 362 kilogs. About 56,314 men were employed at the mines, value of output amounting to 57,906,180 lire, while at the 501 foundries and smelting houses 19,013 men were employed, and value of production amounted to 168,807,406 lire.

## AMERICAN NOTES.

NEW YORK, Oct. 31st, 1894.

THE vigorous protest of the commercial and industrial interests of the United States to the present administration will be recorded next Tuesday, after which a general but gradual improvement in business is assured. Business has declined for two weeks. Prices in iron and steel are perceptibly weaker because of the temporary withholding of orders. Brokers and manufacturers have personal knowledge of extensive requirements for the coming winter for iron and steel, but no orders of any magnitude have been heard of lately. Mill production is restricted to orders in hand. Railroad building has reached its lowest limit. Projected mileage for 1895, if undertaken, would furnish steady employment single turn for the rail capacity. Orders for girder rails keep five or six mills quite busy. Billets have weakened still further. Bar iron has sold at 18 dols. per ton. Pig iron production is promptly absorbed. Commercial conditions are unfavourable. Distribution of merchandise is restricted. Consumers, retailers, jobbers, and all middle interests adhere to the hand-to-mouth course they have been following for eighteen months.

THE report of her Majesty's ship Champion, which recently surveyed Neckar Island, shows that the island is not well adapted for a cable station. Bird Island, 250 miles from Honolulu, which was visited by Mr. Fleming on his recent trip, possesses greater advantages.

## LAUNCHES AND TRIAL TRIPS.

The Campbeltown Shipbuilding Co. launched from its yard at Campbeltown, Clyde, on Friday, a handsomely modelled steel screw steamer of 2000 tons deadweight. The engines, which are triple expansion, are being supplied by Messrs. Kincaid and Co., Clyde Foundry, Greenock. The steamer has long raised quarter deck aft, and part awning deck forward, water ballast in cellular double bottom, complete and speedy pumping arrangements, steam and screw steering gears, and all the latest improvements for navigating the ship economically, and for the speedy loading and discharging of cargo, including large steam winches. Steam will be supplied by a large boiler working at a pressure of 160 lb. The average speed, loaded at sea, is to be 9½ knots on a small consumption of fuel. The vessel has been built to class 100 A1 at Lloyd's under special survey for Welsh owners and is intended for their general trade. The steamer was named Refugio by Miss Bessie Morrison, Altnacraig, Greenock.

On Wednesday there was launched from the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, a very fine steel screw steamer which has been built to the order of Messrs. David MacIver, Sons, and Co., of Liverpool and London, for their River Plate Line. This is the last of three sister vessels which these builders are now constructing for the same owners, all of which are specially designed and fitted for the Plate trade; comfortable and well-ventilated accommodation for the passengers being fitted up in the poop. The vessel is of the partial awning deck type with long raised quarter-deck and poop, and has been built under special survey for Lloyd's highest class, the principal dimensions being:—Length, 305ft.; beam, 41ft. 3in.; depth, moulded, 30ft. 3in., with a deadweight carrying capacity of over 3500 tons on a very light draught of water, and all the deck houses and other deck erections are so arranged that the steamer can be promptly adapted for the carrying of cattle. She will be rigged as a fore and aft schooner, and fitted with Sidgwick's patent hinged topmasts, which can be quickly lowered when the steamer is required to pass under such obstructions to navigation as the permanent bridges over the Manchester Ship Canal. The engines will be fitted by Messrs. Blair and Co., of Stockton, the cylinders being 23in., 37in., and 61in. by 42in. stroke, with two large steel boilers working at 160 lb. pressure, and as the vessel is of fine lines, a good sea speed will be economically maintained. The steamer has been built under the superintendence of Mr. P. H. Roscoe, of Liverpool, superintending engineer to the owners. As the vessel was leaving the ways, she was named the Lombardy by Mrs. Charles Livingston, of Liverpool, the wife of one of the directors, who was presented by Sir Raylton Dixon with a beautiful bouquet of choice flowers.

The s.s. Severus, the third large steel screw steamer built by Messrs. W. Gray and Co. to the order of Mr. C. Andersen, of Hamburg, recently went on her trial trip. Her dimensions are:—Length over all, 340ft.; breadth, 44ft.; depth, 27ft. 2in., and she is classed 100 A1 at Lloyd's. The principal deck erections are a long bridge, topgallant forecastle, and half poop. Large deck houses are built at each end of the bridge to contain the two powerful refrigerating machines, which have been supplied by the Haslam Foundry Company, of Derby, the vessel being fitted out for carrying frozen meat from the Australasian Colonies, and having all her holds insulated for that purpose. The saloon and cabins are tastefully fitted up in the poop and have the entrance through a deck house, which forms a comfortable smoke-room. The engineers' rooms are in deck houses built for them on the bridge, and the sailors' and firemen's berths are in the forecastle. As the Severus is intended to go regularly round the world she is square rigged on the fore mast to benefit by the trade winds, the currents of which are on her course. She has large water ballast capacity in her cellular double-bottom and after-peak tanks. Her boats are carried on beams overhead, and she is fitted with a direct steam windlass, steam steering gear amidships, and screw hand gear aft, steam winches, stockless anchors, and all improved appliances for her special trade, and also for general trading. The engines are of 1200-horse power, of the triple-expansion type, by the Central Marine Engine Works of the builders, who also supply three large steel boilers working at a pressure of 160 lb. per square inch, and which are of ample capacity to supply the freezing engines with steam as well as the main engines throughout the voyage. A day or two before the trial trip both the large refrigerating engines were tried for several hours, and ran in a satisfactory manner. On Saturday last steam was got up and the main engines were moved whilst the vessel remained in dock for the inspection of the head surveyor of the German Lloyd's, from Hamburg, who found everything in connection both with the boilers and engines to his entire satisfaction. The vessel left the harbour at an early hour, and had her compasses adjusted by Mr. Berry, after which the engines were fully opened out and run at a high speed without any hitch or trouble of any kind arising, everything working perfectly well. The speed of the ship was found to be 11½ knots per hour in the trim in which she starts on her Australian voyage, and she will probably average 11 knots around the world. The engines possess all the latest improvements that have been developed at the Central Engine Works, and their steam economy will not be behind any of the well-known examples that have left these works. There is fitted on board a very large sized Mudd's evaporator for making up the supplementary feed, and which is made with a boiler-plate steel shell of neat design and large steam capacity. The propeller is of the loose-bladed type, fitted with blades made of Stone's manganese bronze, and the tail shaft is protected from corrosion by Mudd's patent tail shaft preserver. The vessel is in charge of Captain Berndt. The shipbuilders were represented by Captain J. Murrell, and the engine builders by Mr. T. Mudd.

---

A CONTEMPORARY states that the United States Government is about to make or order 700 6-pr. quick-firing guns as armament for auxiliary cruisers.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

1st *November*, 1894.

20,908. Lamp Holders, H. Lea, London.
20,909. Automatic Attachment for Labels, C. B. Clarke, Norwich.
20,910. Fittings for Holding together Angles of Bedsteads, J. Talbot, Birmingham.
20,911. Steam Joints, W. M. Walters, Liverpool.
20,912. Jewellery Cases, J. C. Roper, Chesterfield.
20,913. Differential Brake for Lorries, R. Mitchell, Glasgow.
20,914. Golf Clubs, W. Park, jun., Glasgow.
20,915. Filling Moulds, &c., with Plastic Fluids, J. Gelder, Manchester.
20,916. Detachable Button and Necktie Holder, E. A. Brown, Keighley.
20,917. Incandescent Electric Lamps, H. H. Hall, Liverpool.
20,918. Preventing Glue-pots, &c., Boiling Over, J. Smith and R. Clayton, Deepfields, near Bilston.
20,919. Securing Detachable Tires to Rims, J. W. Fletcher, Derby.
20,920. Inkwell Covers, J. Wollman, Rotherham.
20,921. Metal Tubes for Boilers, W. B. Thompson, Dundee.
20,922. Self-cleaning Tramway Points, G. H. Winsor, Newport.
20,923. Rudders for Steering Steamships, W. J. Vincent, Cardiff.
20,924. An Aquatic Roundabout, A. J. Budge, Sunderland.
20,925. Golf Clubs, C. Spinks, Glasgow.
20,926. Valve for Washing Machine, F. O'Rorke, Dublin.
20,927. Device for Advertising, P. and F. McGlade, Belfast.
20,928. Fastening Arrangement for Glass, E. Richter, Glasgow.
20,929. Turning Over Music, J. M. Smith, West Bromwich.
20,930. Water-closet Basins, J. Merrill.
20,931. Storing Cycles, W. Kyle, Glasgow.
20,932. Cleaning Boiler Flues, D. Morrisey and F. H. Thomas, London.
20,933. Manufacture of Paper Bags, The Burnley Paper Works Co., and J. Bradley, London.
20,934. Smoke-arrester, J. J. Rendleman, London.
20,935. Valve Stopper for Bottles, J. H. Gault and C. F. Schrader, London.
20,936. Hooks and Eyes, A. L. Milburn, London.
20,937. Tobacco Pipes, J. Roslin, London.
20,938. Racks, F. W. Maishman, London.
20,939. War-ship, G. W. Thomas, London.
20,940. Furnace Tubes, H. C. Ashlin, London.
20,941. Gas Carburetting Apparatus, W. Ritchie, Liverpool.
20 942. Twisting Yarns, S. H. and J. S. Brooks and R. A. Doxey, Manchester.
20,943. Treatment of Water, W. M. Williams, London.
20,944. Telephonic Switch, G. L. Anders, London.
20,945. Can-labelling Machines, E. W. Cornell and F. H. Knapp, London.
20,946. Signalling Apparatus, C. Warren and R. S. J. Fothergill, London.
20,947. Moulding Confections, J. A. Baker.—(*C. H. Grebenstein, United States.*)
20,948. Polishing Metal Plates, S. O. Cowper-Coles, London.
20,949. Turbine Propellers, A. W. F. G. Linnenbrügge, London.
20,950. Axle-boxes, I. Metzger, London.
20,951. Traps for Throwing Targets, R. Millar, London.
20,952. Dress-button, J. Downey, London.
20,953. Mouth-pieces for Pipes, H. O. Thorp, London.
20,954. Production of Motive Power, E. L. Long, London.
20,955. Mowing Machines, E. E. Bentall, London.
20,956. Extraction of Precious Metal, A. E. Morgans, London.
20,957. Replacing Derailed Cars, W. J. Knight, London.
20,958. Ships' Anchors, J. Verity, London.
20,959. Electric Apparatus, A. E. Williamson, E. L. Joseph and The Electric Light Regulating Syndicate, London.
20,960. Engine Governors, A. S. F. Robinson, London.
20,961. Decomposition of Alkaline Chlorides, M. Guthrie, London.
20,962. Connecting Pipes, S. W. Carlton, London.
20,963. Nut Locks, J. T. Drew, London.
20,964. Production of Tiles, F. V. Hardmuth, London.
20,965. Alarum Clocks, E. Edwards.—(*H. Ahlgrimm, Germany.*)
20,966. Packing Railway Sleepers, H. Sadler, London.
20,967. Cigarette Making Machines, F. J. Ludington, London.
20,968. Arranging Sleeping Berths, R. H. Froude, London.
20,969. Air and Liquid Motor Engine, L. Aulit, London.
20,970. Deadening Nerves, D. Young.—(*A. B. Jones, United States.*)
20,971. Making Fertile Materials, C. H. Thompson, London.
20,972. Curing Tobacco, H. A. Wickham and H. Niell, London.
20,973. Stilts, E. Ewerbeck, London.
20,974. Maturing Alcoholic Liquors, H. A. Leverett, London.
20,975. Coal, &c., Grabs, G. J. Hone and C. Wilson, London.
20,976. Finger Protector for Doors, J. W. Rodwell, London.
20,977. Billiard Tables, H. Sale and F. H. Rake, London.
20,978. Wind Motors, A. J. Boult.—(*C. Hoeck, Belgium.*)
20,979. Gullets of Saddle-trees, J. and B. Beebee, London.
29,980. Means for Jointing Rail Ends, W. Lewis, London.
20,981. Dividing House Refuse, J. Eaton and C. R. Powell, London.
20,982. New Steeplechase Game, G. E. A. Fursdon, London.
20,983. Driving Gloves, G. E. A. Fursdon, London.
20,984. Cycles, J. G. Wilkinson and J. Fitzgerald, London.
20,985. Braiding the Strands of Wire Ropes, J. T. Selby, London.
20,986. Fastening the Covers of Umbrellas, H. Pratt, London.
20,987. Combined Collar Studs and Tie-clips, H. Pratt, London.
20,988. Apparatus for Cooling Beer, J. T. Poplawsky, London.
20,989. Gas Meters, H. A. Hicks, London.
20,990. Jugs, F. E. Forteath, London.
20,991. India-rubber Sandal for Boots, J. M. Carter, London.
20,992. New Game, G. L. Prior and B. J. Hyde, London.

2nd *November*, 1894.

20,993. Gearing for Cycles, A. Tracy, London.
20,994. Bag Locks, G. F. Redfern.—(*Messrs. Huppe and Bender, Germany.*)
20,995. Chaff-cutters, E. Scales, London.
20,996. Forming Under-cut Surfaces in Tiles, T. W. Jarrett, London.
20,997. Lubricators, C. Koerte, Leeds.
20,998. Apparatus for Producing Gas, J. Morrison and T. Booth, Stockton-on-Tees.
20,999. Advertising on Sculls, A. W. Loveland and J. and G. Hart, Norwich.
21,000. Infants' Food Warmers, W. Snelgrove and H. Ryland, Birmingham.
21,001. Expelling Moisture out of Bottles, T. Hill, Hull.
21,002. Apparatus for Curling Hair, E. Entwistle, Manchester.
21,003. Safety Carrier, H. Joyner, Stairfoot, near Barnsley.
21,004. Punching and Stamping Machines, W. Rourke, Withington, near Manchester.
21,005. Placquet Closer, A. Nicholson and J. Hall, Staffordshire.
21,006. Brushes for Cleaning Cycles, F. A. Powell, Birmingham.
21,007. Velocipede Saddles, E. Woods, Liverpool.
21,008. Portable Oil Lamps, G. Birch and W. Birchall, Manchester.
21,009. Metal Rims and Pneumatic Tires, A. Dugdale, Manchester.
21,010. Pocket Protectors, J. and E. L. Kavanagh, London.
21,011. Reversing Screw-propellers, F. O. Prince, London.
21,012. Drying Refuse, R. Cunliffe and E. W. Adamson, Manchester.
21,013. Gas Economisers and Purifiers, J. Howarth, Manchester.
21,014. Mules for Spinning, W. Partington, Manchester.
21,015. Mechanism of Pianofortes, P. Nugent and P. Nugent, jun., Carmyle, near Glasgow.
21,016. Indicating Height of Water in Boilers, J. Carter, Stalybridge.
21,017. Starting Trams, J. Milnes and H. J. Champion, London.
21,018. Flexible Shafts, H. Döring, Manchester.
21,019. Metallic Letters, A. J. E. Hill, Kingston-on-Thames.
21,020 Hydraulic Valves, C. Scriven and J. Scriven, Leeds.
21,021. Billiard Cues and the like, J. Hughes, Manchester.
21,022. Locking Cycle Wheels, F. C. Wild, jun., and and J. K. Starley, London.
21,023. Rain, &c., Shade for Vehicles, A. M. Mendoza, London.
21,024. Captive Balloons and Kites, P. S. Pilcher, London.
21,025. Process for Extracting Gold, H. R. Angel, London.
21,026. Folding Box, M. M. Cleckley, London.
21,027. Meat-cutting Machine, M. Lytch, London.
21,028. Internal Combustion Engines, H. F. Foster, London.
21,029. Manufacturing Linoleums, W. G. Thomson, London.
21,030. Carpet Rod Fasteners, &c., A. T. Hughes, London.
21,031. Seams of Waterproof Garments, T. Birnbaum, London.
21,032. Automatically Lighting Gas, J. F. Duke, London.
21,033. Pneumatic Malting Apparatus, E. Larsen, London.
21,034. Motive Power Gear, W. E. Simons, Glasgow.
21,035. Storing Eggs, T. R. C. Christianson, Glasgow.
21,036. Golf Clubs, Sir W. H. Dalrymple, Glasgow.
21,037. Spring Bearings for Cycles, G. R. Sisterson, London.
21,038. Curtain-rod Holder, J. Kott, London.
21,039. Removing Pneumatic Tires, A. J. W. Lambon, London.
21,040. Clips for Garments, J. Hewitt and F. R. Baker, London.
21,041. Mechanism for Rotating Shafts, O. Wernick, London.
21,042. Tires for Wheels of Velocipedes, D. Doig, London.
21,043. Damping Galvanometers, T. Clark and T. E. Weatherall, London.
21,044. Toe Pad for Football Boots, C. Storer, London.
21,045. Dynamo-electric Machines, M. Hutin and M. Leblanc, London.
21,046. Velocipedes, C. E. Stredwick, London.
21,047. Advertising, W. S. and W. F. S. Chenhall, London.
21,048. Tires for Wheels of Velocipedes, D. Doig, London.
21,049. Seed-sowing Machines, C. Gheorghescu, London.
21,050. Closing Preserve Jars, W. P. Thompson.—(*The Conserven-Fabrik Mombach-Mainz von Dr. W. Naegeli, Germany.*)
21,051. Charging Gas Retorts, J. Ruscoe, Manchester.
21,052. Boiler and other Furnaces, J. Sutton, Liverpool.
21,053. Hydraulic Intensifiers, J. C. Etchells, Manchester.
21,054. Increasing Speed in Walking, J. Evans, Liverpool.
21,055. Driving Mechanism of Cycles, G. H. Cook, W. H. Brown, and A. Winsor, London.
21,056. Bricks, S. I. Adams, London.
21,057. Cycles, W. and H. Guest, London.

21,167. Pulley Block Mechanism, E. W. Sant, Stockton-on-Tees.
21,168. Handles for Velocipedes, J. W. Thompson, Lancashire.
21,169. Steering Lock for Cycles, F. Eason, Nottingham.
21,170. Collecting Dust from Grain, E. T. Nicholson, Rochdale.
21,171. Entrapping Steam in Pipes, G. Bennett, Birmingham.
21,172. Hair-pin Holder and Box, T. Geddes, Harrowgate.
21,173. Ventilating Floors, J. Sheppard and F. Dashwood, London.
21,174. Sharpener for Scissors, J. G. Rollason, Birmingham.
21,175. Valves for Power Motors, J. Anderson, Newcastle-on-Tyne.

21,176. Probing Tobacco Pipes, W. Lack and O. Ling, Derby.

21,177. Fire-lighters, J. Maynes and C. L. Watchurst, London.

21,178. Bottles for Poisonous Liquids, A. Winks, Halifax.

21,179. Bevelling Templates, H. Parker, Birmingham.

21,180 Cycle Cranks, G. Pirnie, Dundee.

21,181. Ships' and like Berths, W. P. Hoskins, Birmingham.

21,182. Portiere Rods, F. Hoskins and T. Smith, Birmingham.

21,183. Brushing Sewer, &c., Pipes, W. J. Bosley, Surrey.

21,184. Velocipedes, C. T. Cooper, Leicester.

21,185. Electric Light Pendants, C. T. Powell, Birmingham.

21,186. Steam Engines, W. E. Heys.—(*J. J. Heilmann, France*)

21,187. Cleaning Safety Lamps, G. Grossmann and F. W. Ruhfus, Manchester.

21,188. Blind-cord Racks, A. E. Harris and H. J. Luckock, Birmingham.

21,189. Stiffener for Collars, A. Vorwerk, Germany.

21,190 Cycle Bosses, T. Middlemore and C. Rossiter, London.

21,191 Stamping Notches in Tiles, J. Adams and J. Sherwin, Manchester.

21,192. Box Bedstead, W. H. Hardidge, Weston-super-Mare.

21,193. Automatic Pencil Cases, M. Carmody, Birmingham.

21,194. Sheet-metal Trunks, J. Chilton, Wolverhampton.

21,195. Cycle Chain Gear, The Birch Pneumatic Tire and Wooden Rim Company, Leeds.

21,196. Cycle Wooden Rims, The Birch Pneumatic Tire and Wooden Rim Company, Leeds.

21,197. Fair Lead for Steam Trawlers, T. Sudron, London.

21,198. Folding Boxes, A. C. Moll, London.

21,199. Bookbinding with India-rubber, T. McN. Soul, London.

21.200. Felt-grinding Machines, W. Büttner, London.

21,201. Burning Petroleum, C. Burkill, London.

21,202. Electric Type-writers, G. C. Walker and T. S. Paynter, London.

21,203. Fastenings for Corsets, &c., J. H. Dearle, London.

21,204. Locking Nuts or Bolts, S. J. Cluff, London.

21,205. Starting Races, A. J. Boult.—(*A. Gray, Australia.*)

21,206. Aerating Liquids, R. L. Crawford, Liverpool.

21,207. Railway-signal Apparatus, C. R. and L. C. Alsop, London.

21,208. Score Indicator for Billiards, O. O. Rothwell, Manchester.

21,209. Work-boxes, S. F. B. O'Leary, London.

21,210 Metallic Wheel Tires, J. E. Buckingham, London.

21,211. Enamel Glass-ware, E. Böhm and J. Burchell, London.

21,212. Window-sash Holder, W. Z. Mockett, London.

21,213. Casting Metals, P. Huth, London.

21,214. Locks, &c, L. B. Moreton and J. Stockes, London.

21,215. Spinning Fibrous Substances, W. S. Bancroft, Halifax.

21,216. Gas Burner for Heating, C. Maule, Birmingham.

21,217. Fuel for Fire-places, &c , J. Carter, Bournemouth.

21,218 Electrical Switches, C. P. Ehmann, Manchester.

21,219. Bread, C. G. Jacobsen, London.

21,220 Driving Mechanism for Bicycles, J. Weil, London.

21,221. Wheels, T. and J. Whittingham and M. H. Wilkin, London.

21,222. Manufacture, &c., of Gas, T. L. Willson, London.

21,223. Clasps, R. T. Joy, London.

21,224 Manufacture of Cattle Food, W. Schwartz, London.

21,225. Wire Mattresses, A. H. Gale, London.

21,226 Wire Mattresses, A. H. Gale, London.

21,227. Diazo-compounds, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany*)

21,228. Speed Indicator, E. Ducretet and L. Lejeune, London.

21,229. Novel Dice or Game Box, G. Hayes, London.

21,230. Construction of Loom Pickers, J. Rubirola, London.

21,231. Adjustable Spanner or Wrench, C. Becher, London.

21,232. Railroads and Sleepers, A. Henry, London.

21,233. Field Equipment, J. Wetter.—(*J. Zinn, Denmark.*)

21,234. Guards for Carving Forks, A. S. Daintrey, London.

21,235. Perambulator or Mail-cart, H. E. Murdoch, London.

21,236. Fixing Toilet Glasses, &c., H. A. Burke, London.

21,237. Polling-booth, T. W. Strype and F. Selby, London.

21,238. Attaching Trucks to Ropes, A. Lauenroth, London.

21,239. System for Advertising, &c., J. Henderson, London.

21,240. Cut-off for Lantern Dissolvers, C. G. Norton, London.

21,241. Filtration of Rain Water, &c., J. Clark, London.

21,242. Fireplace and Air Heater, G. Phillips, London.

21,243. Raisin Stoning Machinery, C. L. Spencer, London.

21,244. Locomotive Electric Signal, M. Z Levy, London.

21,245. Smelting, R. Fegan, London.

21,246. Speed Measure, J. F. C. Abelspies and G. H. Rayner, London.

21,247. Game, I. M. Butt and H. S. Whiteside, London.

21,248. Point Locking Apparatus, L. B. Stevens, London.

21,249. Garment Supporters, &c., E. N. Gaillard, London.

21,250. Multiple Telegraph Apparatus, A Piedfort, London.

21,251. Flying Machines, J. L. Osborn and A. Good, London.

21,252. Riddling Apparatus, R. Drake, London.

21,253. Penholders, T. R. M. Byrne, London.

21,254. Cycles, H. Woodier, London.

21,255. Agricultural Implement, A. Warr, London.

21,256. Holding Open Music Pages, W. C. Hamilton, London.

21,257. Braces and Suspenders, A. L. Tighe, London.

*6th November*, 1894.

21,258. Driving Gear for Bicycles, &c , B. R. Mills, London.

21,259. Cutting Confectionery, W. Hart and W. C. Child, Ramsgate.

21,260. Ploughs, J. Hornsby, J. Money, and W. Grice, Grantham.

21 261. Bicycles, &c , J. R. Dedicoat and H. Waterson, Birmingham.

21,262. Construction of Printers' Galleys, T. W. Smith, London.

21,263. Shoot for Loading Coal, W. C. Lockwood, Derby.

21,264. Oil Lamps, G. Moore, Loughborough.

21,265. Signalling on Railways, A. L. M. Edoux and R. Beal, Derby.

21,266. Motive Power for Engine, A. and F. A. Fiddes, Bristol.

21,267. Lever Stair-eye, E. Banks and H. Davis, Birmingham.

21,268. Sliding Chair for Children, H. Robinson, Liverpool.

21,269. Sliding Seats for Carts, J. G. Harrison, Birmingham.

21,270. India-rubber Mats, &c., H. P. Lavender, Walsall.

21,271. Beams and Rollers for Looms, J. G. Harrison, Bingley.

21,272. Waistcoat Cigar Case, A. Sydenham, Birmingham.

21,273. Preventing Colliery Cages Falling, T. Collier and F. R. Smith, Nottingham.

21.274. Badges and Cap Ornaments, H. M. Feinberg, Manchester.

21,275. Construction of Sewers, T. H. Vercoe, London.

21,276. Puff and Powder Container, F. S. Oxborrow, Birmingham.

21,277. Turret for Saddles, F. S. Oxborrow, Birmingham.

21,278. Billiard Ball Collector, F. S. Oxborrow, Birmingham.

21,279. Flanges for Beams for Weaving, J. Steel, jun., Bradford.

21,280. Combined Latch and Lock, G. J. Bowcock, London.

21,281. Temples for Weaving, C. Hahlo, C. E. Liebreich, and T. Hanson, Bradford.

21,282. Making Hinges, J., J., and J. Pritchard, Birmingham.

21 283. Attachment for Beer Engines, A. E. Langley, London.

21,284. Tube Joints, W. M. Walters, Liverpool.

21,285. Trucks, H. O. Thomas, London.

21,286. Keys, A. R. Tonks, Willenhall.

21,287. Producing Patterns on Fabrics, J. A O'Loughlin, Glasgow.

21,288. Cycle Saddles, J B. Brookes, Birmingham.

21,289. Wheels of Road Vehicles, H. W. James, Birmingham.

21,290. Velocipedes, J. M. and W. Starley and F. Westwood, Birmingham.

21,291. Looms, G. and W. B. Richardson, Manchester.

21,292. Looms, G. and W. B. Richardson, Manchester.

21,293. Taps and Valves for Gases, W. A. McCormick, London.

21,294. Machines for Making Pills, &c., L. Thomas, London.

21,295. Pocket-knives, J. Luckock, Birmingham.

21,296. Lock, J. Perks, Stourbridge.

21,297. Opening Soda-water Bottles, G. Moore, Loughborough

21,298. Valves for Liquids or Gases, F. W. Kent, London.

21,299. Playing Balls, R. H. and J. R. Sharples, Manchester.

21,300. Combination Walking Stick, E. Gräbener, London.

21,301. Fork Crowns for Cycles, S. Tweedale and J. Clegg, Rochdale

21,302. Hooks, J Joplin, Sunderland.

21,303. Manufacture of Playing Balls, T. M. Cockroft, Leeds.

21,304. Manufacture of Pouches, T. M. Cockroft, Leeds.

21,305. Disinfecting Water-closets, O. B. Whitehead, Norwich.

21,306. Horse-feeder, A. Cargill, Edinburgh.

21,307. Handles for Buckets, A. Younie, Glasgow.

21,308. Window-sashes, T. Marshall, Glasgow.

21,309. Socket-spanner, W. Tarring, Portsmouth.

21 310. Driving gear for Cycles, S. Farnsworth, Derby.

21,311. Toy Hoop, E Ombler, London.

21,312. Appliance for Use with Pen Nibs, E. C. Wilson, London.

21,313. Ball Cocks, A. Clifford, Dartford.

21,314. Wheel Tires, W. Robin, Glasgow.

21,315. Rack for Letters, J. McHarrie, Glasgow.

21,316. Steam Boilers, W. Glendinning, jun., Glasgow.

21,317. Lamp Extinguisher, G. Butwell and E. Roberts, Birmingham.

21,318. Dandy Rolls, Henderson, Craig, and Co. and E. Rutley, London.

21,319. Propulsion of Cycles, C. C. de Rossetti, London.

21,320. Cycle Gearing, J. F. and D. H. Lewin, London.

21,321. Steam Expansion Engines, A. Eastwood, Liverpool.

21,322. Sewing Machines, W. P. Thompson.—(*C. A. Hill, United States.*)

21,323. Welding Electrically, W. P. Thompson.—(*C. L. Coffin, United States*)

21,324. Printing of Aniline Black, F. Scott and R. J. Flintoff, Manchester.

21,325. Fastenings for Laces, H. W. Clarke, Liverpool.

21,326. Muffle Furnaces, W. P. Thompson.—(*J. Fürbringer, Austria.*)

21,327. Head Coverings, B. W. and H. Russell, London.

21,328. Kettle, E. J. Jones, London.

21,329. Cycle Frames, R. L. Philpot and W. Radford, London.

21,330. Galvanic Batteries, G. Hübner, London.

21,331. Pyroxylin Compounds, R. C. Schüpphaus, London.

21,332. Bottom of Golf Bags, W. Woodhouse, London.

21,333. Water-waste Preventer, T. Jenkins, London.

21,334. Marine Signalling, H. E. G. Earle, London.

21,335. Type-composing Machines, O. Imray.—(*The Cox Type-setting Machine Company, United States*)

21,336. Hair Dye, A. Lumière, London.

21,337. Diaphragm Pumps, O. Imray.—(*F. Syberg, Sweden*)

21,338. Self-fitting Tap for Barrels, W. Sharp, London.

21.339. Moat Dish, W. H. and T. H. Finney, London.

21,340. Double-acting Pump, E. Heuschkel, London.

21,341. Typewriters, A. Sweetser, London.

21,342. Cycles, W. Sutton, Birmingham.

21,343. Angle or Mitre Grip, W. Bazeley, Northampton.

21,344. Treating Cereals, S. Briggs.—(*H. Vuylsteke, Belgium.*)

21.345. Pads for Horseshoes, &c , S. E. Chipperfield, London.

21,346. Valve, H. Birkbeck.—(*The F. Wesel Manufacturing Company, United States*)

21,347. Systems for Telegraphic Exchanges, W. Childs, London.

21,348. Gas Burners, H. E. Newton.—(*R. N. Oakman, jun., United States.*)

21 349. Table Requisite, W. J. Foot, London.

21,350. Knitting Machines, H. H. Lake.—(*J. Millar, United States*)

21.351. Paper Boxes, R. P. Brown, London.

21,352. Paper Boxes, R. P. Brown, London.

21,353. Electric Motors for Vehicles, H. S. Park, London.

21,354 Self-threading Shuttle, H. H. Lake.—(*J. H. Nason and H. M. Hewes, United States*)

21,355. Machines for Hulling Coffee, D. B. Fraser, London.

21,356. Driving Mechanism for Bicycles, E Bellan, London.

21 357. Carpet Lining, C. C. Stewart, London.

21,358. Combination of Materials, G. McDonald, London.

21,359. Boots and Shoes, T. F. Marshall, London.

21,360. Windows, F. C. von Heydebrand und der Lasa, London.

21,361. Embroidering Machines, A. M. Clark.—(*The Kursheedt Manufacturing Company, United States.*)

21,362. Curtain Sticks, C. A. Day.—(*The Brussels Tapestry Company, United States.*)

21,363. Elevator Safety Attachments, C. B. Labatt, London.

21,364. Can-making Machine, R. D. Hume, London.

21,365. Coal and Mineral Washers, E. Ramsay, London.

21 366. Electrically-propelled Vehicles, F. King, London.

21,367. Connections of Battery Receptacles, F. King, London.

21,368. Hauling Apparatus, P. Jensen.—(*M. Langner, Germany.*)

21,369. Folding Scissors, J. Hewitt and F. R. Baker, London.

21,370 Gearing for Measuring-tape Winders, D. G. E. Davies, London.

21 371. Securing Pneumatic Tires to their Rims, G. H. E. and T. Cooke, London.

21,372. Evaporating Apparatuses, B. Abeil, London.

21,373. Chain-making Machines, R. Haddan.—(*P. H. Standish, United States*)

21,374. Dumping Cars, W. G. Lane, London.

21 375. Machines for Cutting Wood, W. J. Perkins, London.

21,376. Flying-machine, J. D. Roots, Teddington.

21,377. Type-writers, J. S. Foley, London.

21,378. Making Infusions, &c , J. R. Fothergill, London.

21,379. Cycle Driving Mechanism, T. Bourne, London.

21,380. Fastening Windows, F. C. B. Robinson, Surrey.

*7th November*, 1894.

21,381. Car Ventilators, A. J. Walker, London.

21.382. Device for Lighting Cigars, P. J. Morris, London.

21,383. New Hood for Ladies' Use, E. L. Dack, London.

21,384. Door Checks, C. H. Mannon, London.

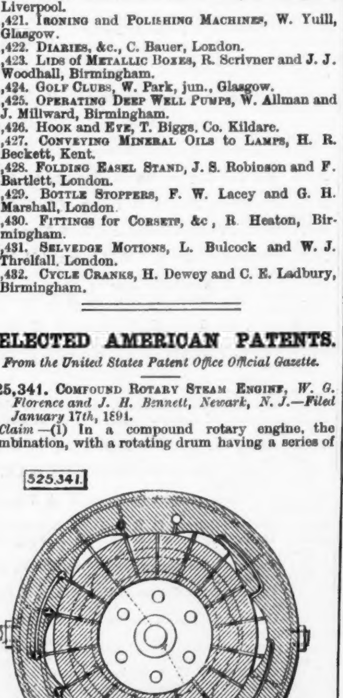
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**525,341.** Compound Rotary Steam Engine, *W. G. Florence and J. H. Bennett, Newark, N. J.—Filed January 17th, 1894.*

*Claim.*—(1) In a compound rotary engine, the combination, with a rotating drum having a series of radial sliding pistons, of a succession of corresponding chambers in a shell around the periphery of the drum into and out of which the pistons move successively, with external passages connecting the chamber in series, and thus leading the same steam in succession through the series of chambers, substantially as herein set forth. (2) In a triple expansion rotary engine, the combination, with a drum having eighteen radially sliding pistons, of a shell formed with six segmental chambers arranged in two groups, with the pistons at the end of the chamber in one group, when in the intermediate position in the other group, heads embracing the drum and closing the ends of the chambers, opposite steam inlets to the first chamber of each group, opposite steam outlets from the last chamber of each group, passages connecting the chambers of each group in each series, and a casing covering all of such passages and forming a steam jacket over the same, substantially as herein set forth.

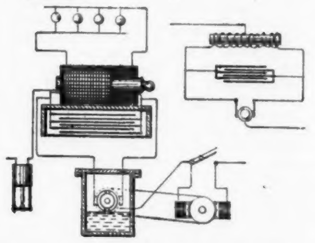
525,341.



**525,369.** Electric Lighting System and Apparatus, *E Thomson, Lynn, Mass.—Filed February 21st,* 1887.

*Claim.*—(1) The herein described system of electric lighting, comprising electric arc lamps run in series on a line or circuit carrying current of high electromotive force, and incandescent lamps supplied with current inductively transferred from the main by an induction coil whose primary is included in the main circuit while its secondary is connected to the circuit of the incandescent lamps. (2) The herein described system of electric distribution consisting of electric arc lamps in series, incandescent lamps in multiple arc, and an induction coil having its primary in the main line and its secondary connected to the line supplying the incandescent lamp branches. (3) In a system of electric distribution, a main or principal circuit having translating devices arranged in series upon it and supplied with current of proper electromotive force for operating such devices in series, a transformer device properly constructed to convert the high tension current on the main circuit into a current of lower tension on the secondary circuit, and incandescent lamps or other translating devices connected in multiple arc to said secondary circuit. (4) In a system of distribution having a main or principal circuit operating translating devices in series therein, an induction coil having its primary connected to said circuit, means whereby the magnetic condition of the mechanism may be changed rapidly so as to be alternately of positive and negative conditions, a secondary coil or coils for the same, and incandescent lamps connected to said secondary in multiple (5) In a system of combined electric arc and incandescent lighting a main electric circuit having arc lamps arranged in series thereon and supplied with current of proper electro-motive force for varying such lamps in series, branches of such main circuit each containing the primary of an induction coil, a continuity preserving circuit changer for closing the circuit through the branches alternately, and incandescent lamps fed in multiple by secondary currents of less tension than those flowing through the arc lamps, as and for the purpose described. (6) In an inductorium, primary or secondary helices either or both of which are suitably mounted, so as to be separated from one another and from the iron mass of the apparatus by a free air space.

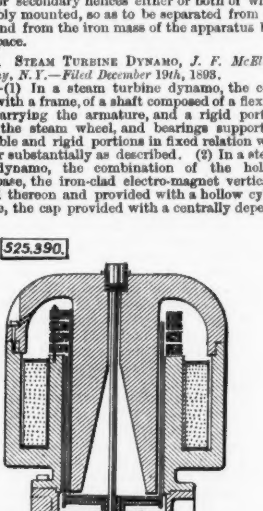
525,369



**525,390.** Steam Turbine Dynamo, *J. F. McElroy, Albany, N.Y.—Filed December 19th,* 1893.

*Claim.*—(1) In a steam turbine dynamo, the combination with a frame, of a shaft composed of a flexible portion carrying the armature, and a rigid portion carrying the steam wheel, and bearings supporting said flexible and rigid portions in fixed relation with each other substantially as described. (2) In a steam turbine dynamo, the combination of the hollow annular base, the iron-clad electro-magnet vertically supported thereon and provided with a hollow cylindrical case, the cap provided with a centrally depending hollow pole piece forming with the case an annular cylindrical field of force within the magnet, the tubular armature forming a suitable electric conductor, the armature shaft extending upwardly into the depending pole piece and flexibly carrying the armature in its axis of rotation, the ball bearing supporting the upper end of the armature shaft, the steam turbine casing secured in the hollow base, the shaft of the steam wheel supported in ball bearings in the casing and united with the armature shaft, and the steam wheel and its flexible connection with the shaft, substantially as described.

525,390.



Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided for our breakfast and supper a delicately flavoured beverage which may save us many heavy doctors' bills."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, by Grocers, labelled, "James Epps and Co, Homœopathic Chemists, London.'

## PRACTICAL STEAM ENGINEERING.

Much has recently appeared in our pages on the theory of heat engines in general, and on that of the steam engine in particular. It is open to doubt, indeed, whether undue prominence has not been given by us to questions which are after all more or less abstract. We believe, however, that such articles as those of Dr. Lodge, and such letters as those of Professor Smith, Professor Alexander, Mr. Cross, and others, can scarcely fail to prove serviceable, notwithstanding the fact that they go over very old paths. More than thirty years ago a tremendous controversy took place in our correspondence pages on the relative merits of high and low-pressure steam. This correspondence was subsequently collected and reprinted in the form of a book. It is interesting and instructive to turn over its pages. The contents of most of them might be printed now in The Engineer without producing the least idea that an anachronism was being perpetrated. Nothing is more curious, indeed, than the way in which the theory of the steam engine has been disputed and re-disputed through a long series of years, without the least prospect of a settlement of any of the questions raised. It is advisable, we think, under the circumstances, that a little should be said now concerning the practical aspect of steam engineering in its most modern presentment.

For many years the philosopher, the scientist, and the mathematician, have been working hard at thermodynamics as applied to "heat engines" or motors. They have taken one road or track and travelled industriously along it. Practical engineers have worked with equal steadiness along a parallel path, on which they have generally managed to keep considerably in advance of the other party. We may suppose, indeed, that the engineers, proceeding in a train, have from time to time thrown out of the windows facts which the philosophers have stopped to pick up, examine, and possibly utilise for their own purposes. It may be said, we think without fear of contradiction, that the steam engine as we have it now owes virtually nothing to the mathematician or the physicist. It has been developed by a method of trial and error by the engineer, and the most that the man of pure science has done is wrangle over the merits of points of practice, the true inwardness of which he in many cases fails to understand. In the practice of steam engineering, moreover, many puzzles present themselves for explanation. They have not been solved yet, and it is doubtful if they ever will be. But amid a great deal of confusion certain facts are available, and it is these facts which, whether they know it or not, are utilised by most engineers who are improving the steam engine.

The steamship owner, the cotton spinner, the locomotive superintendent, care nothing about theoretical questions, their merits or demerits. They want their coal bills kept down. They want the smallest consumption of fuel per horse-power per hour, and they do not care how this desirable end is attained. It is a noteworthy circumstance that no mathematician or natural philosopher has ever been able to devise or even suggest an improvement in the steam engine previously unknown to engineers which would promote economy. It would be useless at this moment for a mill owner, for example, to turn to such a man as Clausius was and ask him for help to save coal. No thermodynamic information exists which can do more for us than the engineer has known, and knows now, without any instruction whatever in pure thermodynamics. If we look back on the history of the steam engine, we find one prominent fact always turning up, namely, that every increase in economy has gone hand in hand with an increase in the working pressure. It may be said that the saving is due to the use of more expansion; so it is, but we prefer to put the proposition as we have put it. The best of the old 10 lb. pressure marine engines required 5 lb. of coal per horse per hour. Then the pressure was raised to 35 lb., and the consumption fell to 4 lb. or 4½ lb. Next came the compound engine, and the consumption fell to 2½ lb. and 3 lb. This was not due to compounding, but to surface condensing—which made the boilers more efficient—and to the augmentation of pressure to 80 lb. Then came the triple-expansion engine, and 120 lb. pressure, and a fuel consumption of about 2 lb. per horse per hour. This was followed by a rise in pressure to 160 lb. and a drop of about half a pound in the coal. The latest development is a quadruple expansion engine working at a pressure of 200 lb. or 250 lb., with a further saving of fuel. Now we wish our readers to dissect these facts out of all the mass of statement, and surmise, and theory connected with the steam engine. Broadly, the truth is that no advance in economy has been secured by alterations in the structure or design of the steam engine unless they have been supplemented by augmented pressure. Of course, we do not mean that there are not bad and good engines to be found working at all pressures. What we do mean is that having hit on a good design, say, of compound engine, no modification in that design, no change in cylinder proportions, &c., will do any good or make the engine more economical, save in a very trifling degree perhaps, while a rise in the working pressure will at once make a change for the better in the coal bills. It is somewhat strange that this truth is constantly overlooked, and nothing is more commonly heard, perhaps, than the assertion that the improvement is not due so much to the use of high-pressure steam as it is to a number of other causes, such, for example, as steam jackets, a diminution in initial condensation secured by reduction of range of temperature in the cylinder, and so on. It so happens that it can be shown that low-pressure steam is just as economical as high-pressure steam. But men forget that this is true only within limitations. We think it will be of service here if we state concisely the reason why high-pressure steam is more economical than low-pressure can be, and in doing so we shall avoid theory, and adhere only to every-day facts.

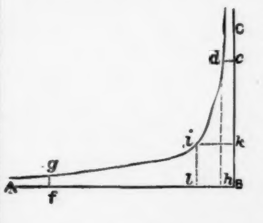
In the first place, then, it is obvious that the indicated power is not a thing of so much importance as the net or brake horse-power; and it should also be clear that a point in expansion must ultimately be reached where the pressure in a cylinder would be so small that it would only suffice to move the engine. A point, in other words, beyond which the indicated power would not represent any brake or useful power whatever. In practice this point is reached in condensing engines when the cylinder pressure falls to 8 lb. absolute per square inch. The average back pressure will be about 3 lb. per square inch, that in the condenser being about 1½ lb. per inch. We are here shutting our ears to theory, which tells us to expand our steam still lower. We are dealing with facts, and as a fact a great body of experience proves that the gain secured expressed in terms of brake horse-power by exhausting at 8 lb. instead of at 10 lb. is very small indeed.

We have here, then, a limit beyond which we cannot carry expansion with any benefit. That is the teaching of practice. In the old low-pressure days it was virtually impossible to use much expansion, because the net horse-power was little increased by it, although there was some small gain per indicated horse-power. The reason why high-pressure steam is more economical than low is simply that the higher the pressure of steam the greater may be the range of profitable expansion, for reasons which have been so fully and so often explained that it is unnecessary to re-state them. The gain due to any measure of expansion is represented by 1 and the hyperbolic logarithm of the range. Thus, for example, if the work of a pound of steam of any pressure be represented by 1 when used without expansion, it will be 1·6931 if expanded twofold, 2·3863 if expanded fourfold, 3·3026 if expanded tenfold, and so on. Now, it will be observed that the logarithms take no cognisance of the pressure; whether it is high or low they remain unchanged. The ratios of expansion are obtained by dividing the initial by the terminal pressure. If, then, we take the terminal pressure as 8 lb. and the ratio tenfold, the initial pressure must be 80 lb. If, however, the terminal pressure was 4 lb., then the initial pressure need only be 40 lb.

Thus, then, those who argue that the economy of a steam engine depending only on the ratio of expansion, it matters nothing what the pressure is, are perfectly right; but their contention overlooks the circumstance that a terminal pressure of 4 lb. is not practical, and that it contemplates an engine whose net power will be too small for the size of the machine. The coal bill may be high per brake horse-power, while the bill per indicated horse-power is small. In practice, an engine too big for its work is always wasteful. But while we see that too low a terminal pressure is a mistake, we also see that too high a one may be very bad. Thus, for example, if we doubled the terminal pressure in the case stated, raising it to 16 lb., we should also have to double the initial pressure, raising it to 160 lb., in order to be able to retain the same tenfold ratio of expansion; and the terminal pressure must not be confused, as it is sometimes, with the condenser pressure.

The moment the exhaust valve opens the engine is done with the steam, notwithstanding what any thermodynamic man, Professor or otherwise, may like to think. We see, then, that if we desire to have large ranges of expansion we must have high initial pressures, simply because low terminals are inadmissible in practice; and the greater the range of expansion the more strongly does this truth enforce itself. If, for example, we expand 20 times, thus getting nearly four times the work out of steam that it can give without expansion, we find that our 8 lb. terminal pressure means 160 lb. initial; while a rise of but 2 lb. in the terminal would mean 40 lb. rise in the boiler pressure. Each pound of terminal pressure multiplied by the ratio of expansion represents the initial pressure; and when, as is the case in some quadruple expansion engines, the ratio of expansion is 30 to one—the hyp. log. of which is 3·4012—we see that the initial pressure cannot be less than 30 × 8 = 240 lb. per sq. in.

To illustrate all this graphically is interesting and useful. It is only necessary to construct a hyperbolic curve, such as that shown roughly in the annexed sketch. A B represents the stroke of a piston. B C the pressures, *d e* = 250 lb., let us say, *g f* 8 lb. The rectangle *d e h* B represents the volume of steam admitted per stroke; the area *d e* B *f g*, the work done. If we halve the initial pressure, making it 125 lb., we shall have the rectangle *i k e* B, which is in area double that first named, and *g i k* B *f* is the work area. Thus, in fact, having constructed our diagram, we can cut any portion we please out of it, working our steam towards one end or the other of it; such lines as *d e* or *i k* always showing the proportion of the piston stroke accomplished before the cut-off closes. Of the effects of clearance, condensation, re-evaporation, &c., we say nothing here. They in no way affect the general terms of our argument, and their full discussion would occupy an enormous amount of space; we only propose to show that the higher the pressure the greater the economy.



Returning now to the consideration of the net as different from the indicated horse-power, it is easy to see that the back pressure will probably be a constant quantity as far as the vacuum is concerned, but it will not be constant as regards the facilities provided for exhaust. Let us suppose that we have a triple expansion engine, the low-pressure cylinder of which is 50in. in diameter, and the piston speed 600ft. per minute. A pressure of 1 lb. on such a piston means 34-horse power, a back pressure of 3 lb. means 102-horse power. Let us suppose that the initial pressure is 160 lb. absolute, and the ratio of expansion twentyfold, the average pressure will be 32 lb. on the square inch, representing 34 × 32 = 1088-horse power. But from this we must deduct 102, leaving 966-horse power effective. If, now, the consumption of fuel was, say, 2176 lb. per hour, the rate per indicated horse-power would be 2 lb. Let us augment the back pressure to 7 lb. per square inch—which we found to obtain in a triple expansion marine engine which we indicated not long since—and the indicated power falls at once to 840, and the consumption becomes 2·6 lb. nearly. But a saving of half a pound per horse per hour is keenly sought for; considerable complications, expense, and trouble will be willingly incurred to secure it. It may represent the whole difference between a cheap compound engine and a dear triple expansion engine, occupying much more room, and yet whether the saving is or is not obtained may all depend on the design of the exhaust valve. Of course, the lower the terminal pressure, other things being equal, the larger will be the low-pressure piston and the greater the influence of back pressure. It is, indeed, not too much to say that in many instances a drop of 2 lb. in the back pressure would confer a much greater benefit than an increase of 40 lb. in the boiler pressure. But we fear it must be admitted that in the best modern engines the back pressure has been brought down to the lowest possible limit, and nothing remains for those who seek a higher economy than higher boiler pressures.

We confess that in all that we have written we have had the marine engine in mind, but much that we have said will of course apply to any engine. The practical engineer has learned by experience that it will not do good to reduce his terminal cylinder pressure much below 8 lb.; of course the pressure at the precise end of the stroke will be less, but this does not affect our argument. He also knows by experience that every augmentation of the range of expansion is, within limits, conducive to economy. We have shown that it is impossible to augment this range downwards. Looking at the sketch diagram, we see that we cannot utilise any portion of it beyond *g f*, but at the other end we can go very much farther than we have gone yet. The difficulties and objections which interfered with the adoption of high pressures years ago are being disposed of by degrees. The tubulous boiler has made great progress during the last ten years, and it is now quite possible to generate steam of 250 lb. pressure with safety and economy. Metallic packing has been so far improved that piston-rods can be run steam-tight for long periods without giving much worry to the engineer in charge. Lubricating oils are made which will endure the great heat. The greatest difficulty met with at present consists in getting gauge glasses which will not soften and dim. Mr. Perkins worked up to 400 lb., using talc, and no doubt the difficulty may be overcome in time. As matters stand now we find that practical marine engine builders care little, if at all, for jacketing or superheating. They are now and have been for some years depending entirely on increased ranges of expansion for increased economy, and it has never failed them yet. In a tentative way other expedients, such as superheating, have been and are being tried. But marine engine builders know that such things do not mean serious business; they do not count in competition for orders from shipowners. Higher pressures "mean money;" the other things do not—at least at present; and this is the reason why so much is being heard just now both in this country and abroad concerning quadruple expansion engines. It is very easy to argue that other expedients than quadrupling are available; that they would be cheaper and better. That may be, but up to the present it is a suggestive and remarkable fact that nothing but increase of pressure has been found to stand the test of practical work. Whether or not this state of things will continue to the end we do not pretend to say; but that is quite another subject. We have endeavoured to write of steam engine practice as it is, and not as it may be.

---

Engineering Society, King's College, London. — A general meeting was held on Friday, November 16th, the President in the chair. Mr. Kelly read a paper on "Continuous Railway Brakes." He first gave a short historical sketch of the brake question, and then described the various typical forms of brake. The rest of the paper consisted of detailed descriptions of the vacuum automatic and the Westinghouse brakes, aided by models and diagrams lent by the brake companies.

A Dead Industry.—Next Monday evening at a meeting of the Lantern Society, at 20, Hanover-square, London, will be an exhibition of relics of the past by Mr. J. Hay Taylor, likely to carry the memories of many of those present back to their childhood's days, the curiosities being none other than the original old dissolving view lanterns of the palmy days of the Polytechnic Institution, and a selection from among the great painted lantern slides which once delighted the the juvenile population. Practically speaking, photography has about killed lantern-slide painting as an art, although colourists are now numerous. Great skill was required in the work, from the magnification to which the results were afterwards to be subjected, and men who could paint those pictures well were few and far between. The late Mr. Westley, of the firm of Carpenter and Westley, encouraged those who had skill in the work, among whom were Messrs. S. H. Baker, J. Smith, Thomas Clare, Thomas Kearnan the cleverest painter of architectural slides, Henry Childe an expert at scenic effects, such as rippling water, summer and winter landscapes, and moonlight effects, Charles Simpson a miniature painter by profession, and C. Constant, who made himself immortal by painting the original of the world-famous slide of the sleeping man swallowing rats. Nearly if not quite all of these have gone to their rest. Kearnon and Simpson were buried in the same grave in Brompton Cemetery by the late William Westley. The first to make magic-lanterns in this country was Philip Carpenter, who began their manufacture in Birmingham, about 1808. He was the uncle of the late Dr. W. B. Carpenter, the physiologist. The old Polytechnic lanterns and some of the slides have been lent to Mr. Hay Taylor for exhibition next Monday by Mr. Edmund Wilkie, who had much to do with the Polytechnic, and who, at the sale by auction of the effects of the company, bought up many hundreds of the slides, and the lanterns. The condensers of the lanterns are 10in. in diameter. The size of the actual pictures on the slides is 7in. by 6in. In a parody of the Incantation Scene in "Der Freyschutz" at the Polytechnic, sixteen slides were employed. All the six lanterns were working at once, and four operators were engaged in producing the effects. Is it possible that the public taste for the glory of colour artistically applied to lantern slides may revive? About the best coloured slides seen in this country within the past two years were painted in Japan by native artists, and were exhibited at a meeting of the Richmond Camera Club.

## THE GREAT NORTHERN RAILWAY COMPANY'S GOODS DEPOT, FARRINGDON ROAD.

In view of the enormous increase of goods traffic to and from the metropolis which has of late years developed itself, and will in the future undoubtedly go on increasing, the Great Northern Railway Company has found it imperatively necessary to enlarge the goods station at Farringdon-road. The existing warehouse, which consists of a basement, with a floor at street level and two floors above, which we described and illustrated in our issues of February 11th and 18th, 1876, at that time in course of construction, is situated on the north side of Charles-street adjoining the Farringdon-street Station of the Metropolitan Railway Company, and has a frontage extending along Farringdon-road of a little over a hundred yards, the frontage to Charles-street being 92ft. for the warehouse and 42ft. for the offices, which join the Metropolitan Company's station.

At the times when the Corporation of the City of London built the markets now known as the New Fruit and Vegetable Market, the General Produce Market—formerly the fish market—and the New Fish Market, they excavated the ground beneath these markets to the level of the rails of the Metropolitan and London, Chatham, and Dover Railway, or to a depth of about 28ft. below the level of Farringdon-road. The whole of this area beneath the markets has now been leased by the City Corporation to the Great Northern Railway Company, and the depôt now extends from Snow-hill on the south to the familiar chimney at Vine-street on the north, a total length of about 700 yards, or nearly half a mile.

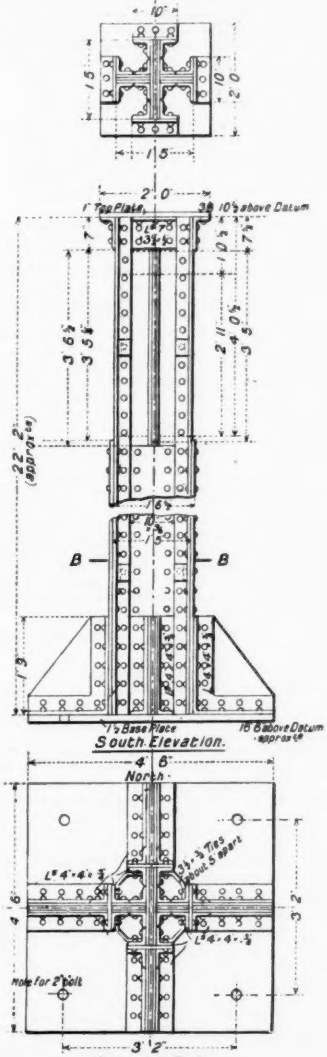
The basement of the new portion of the depôt, therefore, extends from Charles-street southwards to the New Markets, and underneath them and Charterhouse-street to Snow-hill, occupying the space between Farringdon-road and the Metropolitan and London, Chatham, and Dover Railways, a total area of about 3½ acres. Access to this basement has been provided by two inclined roadways, one from Charles-street on the north, which was constructed by the Great Northern Company, the other from Snow-hill on the south being constructed by the Corporation at the time the markets were erected. The northern inclined roadway to the basement is constructed on a viaduct, the first opening of which is about 45ft. span, built of steel girders and steel trough flooring, and of sufficient headway for the passage of fully loaded vans in the basement. The remainder of the viaduct is of brick arches, which have been made use of for the purposes of stables, mess-rooms, &c. The roadway is on a gradient of about 1 in 20.

To connect the new with the old portion of the depôt, a steel bridge, 60ft. span and 40ft. wide, had to be built under Charles-street. It was also necessary to build another steel bridge 150ft. span and 60ft. wide under Charterhouse-street, each of these bridges being constructed half of its width at a time, so as not to interrupt the vehicular traffic in those thoroughfares—no easy matter in such crowded and busy thoroughfares. The new portion of the depôt between Charles-street and the new fruit and vegetable market consists at present of the basement, and a floor at street level with a roof over. It being in contemplation to erect three more floors at some future date, when the exigencies of the traffic demand it, all foundations, stanchions, &c., are therefore calculated and built of sufficient strength to take the additional loads which will then be brought upon them. The present roof stanchions and roof will then be taken down and re-erected at a higher level. The floor of the new depôt at street level will furnish a superficial area of nearly an acre, and will be occupied, like the basement, by docks and platforms for the loading and unloading of goods, and by carting space for the accommodation of vans engaged in the collection and delivery thereof.

This floor is carried on girders supported on forty-one steel stanchions, the foundations for which it was found necessary to carry down to a depth of 10ft. below the level of the rails in the basement, in order to get a firm bearing on the solid clay. Whilst the excavations for the foundations of the stanchions were in progress, a number of sewers and drains were unexpectedly discovered, crossing the ground in many directions. Some of these, which were still in use, had of course to be diverted, and the disused ones filled up or removed before the work could proceed. As in the old depôt, during the progress of the excavations a vast quantity of bones, evidently of horses or cattle, were discovered, doubtless having been buried many years ago.

In constructing the inclined roadway to the basement from Charles-street, which runs parallel to and adjoining Farringdon-road, it was found necessary to underpin to a depth of 5ft. the high retaining wall which was built several years ago by the Metropolitan Railway Company, which difficult operation was successfully carried out in very short lengths at a time. Great care was necessary during this part of the work to avoid any settlement which might have affected the safety of the Fleet sewer, which runs in close proximity.

The foundations for the stanchions vary slightly in size, and consist of a bed of Portland cement concrete in the proportion of six to one, 3ft. thick, covering an area on the average of 235 superficial feet each; on the top of the concrete to a height of 3ft. 6in. Staffordshire blue brick footings are built, the area at the top being about 60 superficial feet, resting on which are the bedstones of grey Cornish granite, 2ft. in thickness, and 6ft. square, having sinkings 4ft. 6in. square to receive the ends of the stanchions, which are held down by No. 4 bolts of 2in. diameter. The greatest working load per superficial foot on the solid clay has been taken at four tons, that on the concrete at ten tons, on the Staffordshire blue brickwork at twenty tons, and on the granite bedstones about forty-five tons.



Section B-B.

DETAILS OF ORDINARY STANCHION

The whole of the stanchions, girders, and flooring are made of Siemens-Martin mild steel of first-rate quality, and capable of sustaining a tensile strain of not less than twenty-eight tons and not more than thirty-two tons per square inch, with an elongation of 20 per cent. in 8in. in the direction of its fibre. The working stresses for the steel have been calculated at six tons on the square inch for the stanchions, and as regards the girders, seven tons per square inch in tension, and six tons per square inch for shearing stress.

The stanchions in the basement are 22ft. long, and average about 1ft. 8in. square, calculated to carry about 900 tons each, which will be the load upon them when the warehouse is completed in the future. Hitherto the usual box or hollow section has been used, but these have been found to be objectionable on account of the impossibility of ascertaining the amount of oxidation going on in the interior, consequently no certainty existed as to the actual serviceable condition of the stanchions. In these stanchions, however, a new departure has been wisely taken as regards the shape or cross section. They have been designed and built in the form of two double T girders crossed, and connected together at the centres by angles. A reference to the engraving will at once explain the form more clearly. As will be seen, in this form, the whole of the surfaces are exposed to view, and can be easily painted and their serviceable condition ascertained at any time. The bases are spread out to about 4ft. 6in. square, having a base plate 1½in. thick bedded on two thicknesses of asphalted felt, and let into the sinkings of the granite bases. The top plates of the stanchions are 1in. thick, planed perfectly true to receive the stanchions on the ground floor level.

The main girders are of the ordinary plate girder type; they are forty-seven in number, varying in span from 30ft. to 40ft., and in depth from 3ft. 1½in. to 4ft. To these—and in some cases to the stanchions—are attached the cross girders, also of the ordinary plate girder type, 114 in number, 10ft. apart, mostly in 26ft. and 30ft. spans, and 3ft. in depth; the lower plate of the top flange of these cross girders projects on either side for the purpose of riveting the trough flooring to them.

The steel trough flooring, of which about 300 tons has been used, covers the whole area between Charles-street and the new Fruit and Vegetable Market, except where the traverser and wagon hoists occur. It is 6in. in depth, and ⅜in. thick, and weighs 24 lb. per foot super of area covered. The connection of the girders to the stanchions has been effected by continuing the web of the girder through into the stanchion, thus practically forming part of the stanchion itself, and making a good firm connection, the result being that the whole of the immense overhead network of girders is securely combined into one substantial whole. The steel trough flooring is filled in with Portland cement concrete in the proportion of 5 to 1 to a few inches above the top of the troughs, on which, for the carting space, is laid a bed of cement 1in. in thickness to receive the Val de Travers asphalte, which is 2in. thick.

The whole area of the basement, except under the platforms, has been paved with granite setts laid on a 6in. bed of concrete, and sidings and turntables have been laid in, and connections made through the new bridge under Charles-street with the old depôt. The carting space at street level, access to which is obtained by two entrances from Charles-street, runs round three sides of the platform, so that a great number of vans can be unloading or loading, as the case may be, at the same time. Provision is made on this floor for the reception of fourteen trucks, which are brought up from the basement by two hoists provided for this purpose and worked by hydraulic power, each capable of lifting twenty tons. The trucks are then transferred to a traverser, also worked by hydraulic power, which runs across the centre of the floor and deposits them in any of the bays or sidings which may be empty to receive them. Advantage has been taken of the space between the rails on which the traverser works to admit light to the basement, by inserting pavement lights for its whole length of 125ft. and 9ft. in width. The platforms, or "banks" as they are called, are constructed on timber framing, those in the basement being covered with light steel troughing filled with concrete and asphalte, while those on the street level floor are covered with 4in. planking, securely bound at the edges with wrought iron bent plates ¼in. thick.

The stanchions to carry the roof are twenty-eight in number, and are of similar shape to those below, but of a much lighter and smaller section, and about 22ft. in length. These are bolted to the ones below by No. 4 bolts of 1¼in. diameter.

The girders carrying the roof trusses are plate girders, thirty-one in number, nineteen of which are in spans of 30ft. with a depth of 2ft. 6in. It was found necessary to make the remaining twelve girders, which are over the carting space, of spans varying from 42ft. to 64ft., and of a uniform depth of 4ft. 6in., so as to avoid having any stanchions standing in the carting space in the way of the traffic. All these roof girders are attached to the stanchions in a similar manner to the main girders below, with this exception, that the webs are continued right to the centre of the stanchions, being riveted to the outer angles of them and fastened to the inner angles —where it would be difficult to rivet up—by No. 9 ¾in. bolts in the case of the long girders, and No. 7 ¾in. bolts in the case of the shorter girders. Across the tops of the girders, every 6ft., are riveted two pieces of angle 1ft. 4in. long by 4in. by 3½in. by ½in., with a ⅜in. space between them, and packed up where necessary, so as to bring all up to the same level, to receive the ends of the T rafters of the roof trusses.

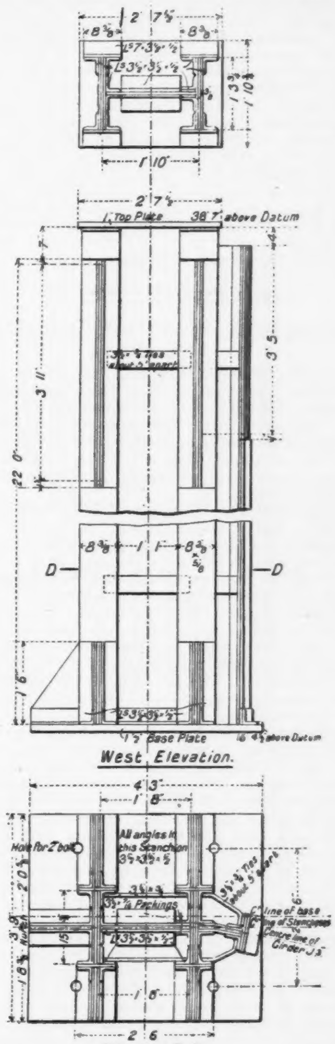
Each of the five rows of roof stanchions are tied together transversely at the top by means of light lattice girders 2ft. deep, riveted to the outer angles. Two more of these lattice ties are fixed across the building, where the large span roof girders occur, thus giving seven continuous ties running transversely across the whole width of the building. The roof, the trusses of which are constructed of steel, covers the new depôt, with the exception of the inclined roadway to the basement, in five bays; the irregular shaped piece between the last bay and the Metropolitan Railway on the eastern side of the depôt being covered over by a zinc flat supported on rolled steel joists. The roof principals, placed 6ft. apart, are of T steel 2¾in. by 2¾in. by ⅜in. thick. The struts are are also of T steel of the same section, and the tie-bars are 2in. by ⅜in., and 2½in. by ⅜in. flat bars. The roofs have broad skylights, admitting of ventilation on either side of the ridge, the remainder being covered with best Bangor Countess slating, on 1in. matched and beaded boarding, wrought one side. The gutters are of cast iron, 18in. wide and 6in. deep, and have been made in 6ft. lengths with flanged joints, resting in cast iron shoes bolted to the girders. The down pipes to carry off the rain water are placed in the angles of the stanchions—see page 444—and are collected together underneath the platform at street level, and thence taken down the eastern wall of the depôt direct into the sewer.

Before the wall on the eastern side of the depôt could be built, it was necessary to remove the old brick and concrete retaining wall, built many years ago by the Metropolitan Railway Company, which being done, an entirely new warehouse wall 270ft. long and 54ft. in height, with blue brick piers to receive the girders, was erected in its place, having numerous window openings fitted with "Moline's" patent wrought iron sashes.

The western side of the new portion of the depôt between Charles-street and the new fruit and vegetable market, and adjoining the inclined road down to the basement, is enclosed by a timber screen attached to the stanchions and to vertical steel joists carried on the floor girders and placed about 10ft. apart, there being in each 10ft. bay a window 9ft. high by 4ft. 6in. wide, with casement at top. Beneath the girders under this screen are vertical pavement lights for the purpose of admitting light to the basement. When, as has been contemplated, a row of handsome shops or offices is built over the half of the inclined roadway next Farringdon-road, this screen will be hidden from view from that thoroughfare.

Consequent upon the enlargement of the depôt, it was found necessary to provide extra office accommodation for the largely increased clerical staff. This has been accomplished by erecting a convenient block of offices of three floors on the Charles-street front of the depôt, between the two entrances to the carting space. The front wall of these offices, which is carried upon three heavy steel box girders, each about 30ft. long and 4ft. deep, is faced with Fletton buff bricks, the arches over entrances and window openings being turned in red Leicester bricks, having a keystone of Portland stone. The pilasters are rusticated for a height of 22ft., and the string courses are of Portland stone and moulded bricks, the plinth course being also of moulded bricks. The general tone, as regards colour, and the character of the ornaments are very pleasing in effect. Pavement lights, both vertical and horizontal, have been introduced in front of the offices, in order to give as much light as possible to the basement of the depôt.

For the convenient working of the new depôt there have been provided in the basement ten new cranes, with a lifting power of 30 cwt. each, and fourteen capstans; and on the ground floor seven cranes of the same lifting capacity, all being worked by hydraulic power. Besides the two wagon or truck hoists before described, two smaller hydraulic hoists have been erected, to connect the basement of the new depôt with the new fruit and vegetable market. These have each a lifting capacity of 2¼ tons, and will prove a great and invaluable convenience in conveying consignments of fruit and vegetables directly from the trucks below to the market overhead. The whole of the hydraulic cranes, capstans, hoists, and the accumulator, with all the necessary pressure and return pipes, &c., have been supplied and fixed by Messrs. Tannett Walker and Co., Leeds.



Section D-D.

STANCHION UNDER FRONT OF OFFICES

The present hydraulic station at Vine-street was found to be totally inadequate to work all these extra hoists, cranes, and capstans; it is therefore being enlarged to treble its former capacity. A new pair of engines, supplied by Messrs. Tannett, Walker and Co., are being erected, also three new Babcock and Wilcox boilers, each containing 2920 square feet of heating surface, and rated at 450 indicated horse-power each, and one Babcock and Wilcox fuel economiser, with necessary dampers to put it out of work without affecting the working of the boilers. A new chimney has been built, 120ft. in height, 13ft. 6in. square at the base, tapering to 7ft. 3in. square at the top, being 5ft. square inside; it is lined to a height of 20ft. with fire-brick 9in. in thickness, and for the next 20ft. with a similar lining 4½in. thick. The cap of the chimney is of cast iron of ⅝in. metal, weighing over three tons, and is filled in with concrete faced on the inside with bricks, alternately headers and stretchers. New flues had also to be constructed leading to the new chimney shaft, all of which work had to be carried out without interfering with the working of the old engines and boilers. A new accumulator has been erected at the north-east corner of the new portion of the depôt. The water is delivered for work at a pressure of 700 lb. to the square inch.

In the several contracts for the construction of the before-described works in the new portion of the depôt, about 35,000 cube yards of excavation had to be done, a great quantity of which consisted of old walls and foundations of hard concrete, and which cost on the average about 5s. per cubic yard to remove. There has also been used in the new work about 7500 cubic yards of Portland cement concrete in foundations, &c., and about 4200 cubic feet of granite in stanchion bases, &c. The area of granite paving laid down is no less than 10,500 superficial yards, and the quantity of steel used in stanchions, girders, flooring, rolled joists, roof trusses, &c., reaches the large amount of nearly 1800 tons.

About 2200 lineal yards in permanent way in sidings has been laid in the new depôt, making a total of nearly 2¼ miles of sidings in the whole depôt. Twenty-two new turntables have been laid in for the more convenient working of the basement. About 22,000 superficial feet of platform area has been provided in the new depôt, making, with that in the old depôt, a total platform area of about 37,500 super feet.

The above facts and figures unmistakeably show the vastness of the works which have been undertaken, and which are now nearing completion. There can be no doubt that this depôt can now be ranked as one of the, if not the most convenient and commodious goods station in all London. Situated as it is for the greater part within the boundary of the City, and yet within easy access of the most important business thoroughfares of the West End, the Great Northern Company will now be able to considerably relieve the congestion of traffic which has faced them for some time past. Already the basement of the new depôt is in full working, and the works are being so rapidly pushed forward that the remainder will shortly be opened for traffic.

It is characteristic of the completeness with which the work has been carried out that the whole of the depôt, both old and new, is to be lighted by means of the electric light. It was originally contemplated to bring the electric current for this purpose from the company's new electric light station at Holloway, but, after mature consideration, it has been decided either to establish a separate installation near the hydraulic station at Vine-street, or to obtain it from one of the City electric supply companies. The company has also established a system of telephone communication, connecting all their London depôts, including Farringdon-street, Bread-street, Whitecross-street, &c., with their goods yard at King's Cross, as also with their chief goods offices at that station.

The new works have been designed and carried out under the direct supervision of Mr. Richard Johnson, M.I.C.E., the chief engineer of the Great Northern Railway Company. All the steel and ironwork has been supplied and erected by Mr. Matthew Pitts, of Stanningley, near Leeds, the whole of the remainder of the works being undertaken and executed by Messrs. Atherton and Co., of Poplar.

## PENETRATION AND ACTION OF SMALL-ARM BULLETS.

THE October number of the United States Institution "Proceedings" contains extracts from the report of the Small-arms Penetration Committee—president, Colonel Fraser, R.E.—and also from a paper by Lieut. Benet, Ordnance Department U.S. Army, on "The Effect of Small-arm Bullets on Animal Tissue." Thus, we have before us the effects which we may expect of our new rifle fire on *matériel* and on men.

It appears that the Mannlicher 0·256in. bore, with a 160 grain bullet, and a muzzle velocity of from 2300 to 2400 foot-seconds was tested in comparison with a Lee-Metford 0·303in. bore firing a bullet of 215 grains with a velocity of from 1975 to 2000 foot-seconds, also a Martini-Henry 0·450in. bore with a bullet of 480 grains and a velocity of from 1270 to 1300 foot-seconds. The Mannlicher velocities fell off rapidly during the firing of 1000 rounds owing to erosion of barrel. The Lee-Metford fired 3000 without being affected; 150 rounds of the Mannlicher weighed 7·271 lb., against 8·807 for the Lee-Metford. The trajectory of the Mannlicher was naturally flatter than that of the Lee-Metford, and the accuracy of the former was also slightly superior.

As to penetration, the bullets perforated a 9in. brick wall with ½in. boards at the joints, though the bricks resisted the bullets. At 100 yards the joints of a 9in. wall and seven ¾in. deal boards were penetrated, and at 400 yards even some of the bullets got through the joints and two ¾in. deal boards, and even of a 14in. wall and two ¾in. boards. At 600 yards the joints of a 4½in. wall and seven ¾in. boards were perforated. At 200 yards 200 bullets were sufficient to breach a 9in. wall so as to allow a man to pass through—the hole measuring 24in. by 15in.; 1028 rounds were needed to make a smaller breach in a 14in. wall. The firing was chiefly in volleys of fifty. Brick walls 9in. thick, with ⅜in. joints of hard mortar, resisted the bullets, so that such walls set in cement may be used for defence, but joints should be broken horizontally as well as vertically, it is said; but it appears as if this would make any bond difficult. Sun-dried brickwork 18in. thick is bullet proof, except to very long-continued firing. Curiously, at very short ranges, bullets set up and penetrate less than at 400 yards. A wall 9in. thick, made of burnt tiles set in mud, was perforated by the smaller bores, but kept out the Martini-Henry bullets. Volleys produced better effect than independent firing. Fresh mud walls required to be 4ft. thick to stop the bullets.

Mild steel or wrought iron 0·44in. stopped bullets, and at ranges over 60 yards a 0·206in. plate of hardened steel stopped the Lee-Metford bullet, and a 0·25in. hardened steel plate stopped the Mannlicher at short ranges, and is recommended for sap shields. At 500 yards a hardened steel plate less than $\frac{1}{10}$in. thick, weighing only 3 lb. 10 oz. per square foot, stopped everything, and might serve for field artillery shields. So great is the penetration of small-bore bullets through both wet and dry timber that standing trees and timber balks will seldom offer much protection at ranges under 1000 yards. On the other hand, sand has high resisting power against bullets with high velocity. The Lee-Metford bullets will not penetrate 18in. of sand at any range. The Mannlicher at short range breaks up and penetrates less than the Lee-Metford. Three inches of large flint shingle between boards smashes and stops all bullets at all ranges. Fine shingle is rather less effective. The new bullets penetrate 3½ft. into moist clay at close distances, and 28in. into loam. A cotton bale 20in. thick, end towards firer, stopped all bullets ever fired at 25 yards distance, but some perforated the bale side on. At 500 yards, bullets penetrated 7½in. end on and 13in. side on. Stockades of double planks with sand or macadam of roads between will probably replace heavy timber. A coal sack 12in. thick is impenetrable.

It may be seen that the key to these effects appears to us to be that as the velocity increases, resistance due to inertia tells much more than resistance due to cohesion. Wood is easily perforated, because a bullet of small calibre with a high velocity is suited to cut it through easily, but in sand and shingle the actual particles have to be displaced, which becomes more difficult as the velocity increases. Hence the bullet fails to make way and breaks up.

As to flight, the Martini-Henry bullet travels faster than sound up to 800 yards, the Lee-Metford and Mannlicher are both overtaken by the sound at about 1600 yards—the former bullet overtakes the latter at about 1500 yards, which is remarkable, the latter having the greatest sectional density.

We now pass to the United States experiments on animal tissue and bones, as reported by Lieut. Benet. The rifles used were the 0·45in. and 0·30 Springfield with 500 and 220 grain bullets respectively. The "Cadaver"—apparently a human body—was placed fifty-three yards from the rifle, and the charge was reduced to give the striking velocity corresponding to 100, 150, 200, 250, 350, 500, 800, 1200, 1500, and 2000 yards. Two hundred rounds were fired. The 0·45in. bullet gave what is termed explosive effects up to 250 yards range, and the 0·30in. up to 350 yards, the bullet being generally badly deformed and the jacket more or less stripped off. Explosive effect is less when the bullet is not deformed. Bones were less shattered by the 0·30in. bullet than by the 0·45in. Sometimes bones were completely perforated without splintering. In joints and soft parts the smaller bullet also inflicted less severe wounds. This is contrary to results obtained in England with horse bones, which, being harder, were broken and splintered in a terrible way. This is easily accounted for, but at the same time it could not have been foreseen. As is pointed out, the action of the bullets may have been considerably affected by the fact that the rotation was only proportionate to the velocity, whereas a bullet fired at a high velocity loses its onward velocity out of all proportion to its velocity of rotation, and the latter may increase the shattering effect. As to flesh wounds, we may add what perhaps many of our readers may know, that animals may be shot through fleshy parts without knowing that they have been struck at all. It is questionable if determined men could be stopped in a rush at close distances as well with small-bore as larger ones, but we think that experiments are needed to determine the influence of rotation as well as velocity before we can build on the United States experiments.

## THE INSTITUTION OF CIVIL ENGINEERS.

### THE MACHINERY OF WAR-SHIPS.

AT the ordinary meeting on Tuesday, the 20th November, 1894, Sir Robert Rawlinson, K.C.B., the President, in the chair, the paper read was on "The Machinery of War-ships," by Mr. Albert J. Durston, Engineer-in-Chief of the Navy.

In this communication the particulars were given of the ships with forced draught which preceded the Naval Defence Act of 1889, and of those of the seventy ships ordered under that measure; while in an appendix were tabulated the details of the several vessels referred to. In regard to the period preceding 1889, a salient feature was the gradual adoption of steel tubes for the boilers, in place of those of iron, which had previously superseded the brass ones formerly universal in the Navy. Between the years 1884 and 1889 considerable changes had taken place in the types of engines used for propelling the ships, the two-cylinder compound engine having generally given place to that with three cylinders and triple expansion, the steam pressures rising from 90 lb. in most battle-ships to 155 lb. for the heavily-powered cruisers of the Blake class. During this period the type of vessel known as the "torpedo-gunboat" had appeared.

The seventy vessels built under the Naval Defence Act of 1889 included ten first-class battle-ships, nine first-class cruisers, twenty-nine second-class cruisers, four third-class cruisers, and eighteen torpedo-gunboats. Of the hulls, thirty-two were built by contract, and thirty-eight in the Royal Dockyards. Of the machinery, that for sixty-three vessels was supplied by contract, and that for seven was built by the State. A general description of the machinery of each type of vessel was given. In the battle-ships the ratio of volumes of the high to the low-pressure cylinders was 1 : 4·84, with the exception of the Barfleur and the Centurion, where it was 1 : 5·37. The natural draught power was 9000 indicated horse-power, the full power being 13,000 indicated horse-power, although the valves—except in the case of the Royal Sovereign — were afterwards arranged for a maximum of 11,000 indicated horse-power.

In the first-class cruisers the dimensions of the cylinders were identical with those of the battle-ships—except the Barfleur and the Centurion. These vessels were designed for a full power of 12,000 indicated horse-power, but, as in the case of the battle-ships, the propellers and valve-gear in most of them were subsequently arranged for a lesser power, so as to enable them to steam more economically at the low power usual when cruising. The higher power could, however, be developed at any time by suitable modifications in the valve-gearing and propellers. The ratio of cylinder volumes in the first-class cruisers was also 1 : 4·84.

The machinery of the second-class cruisers was similarly arranged to that of the first-class, the ratio of cylinder volumes being 1 : 4·88 for nineteen of these vessels, and 1 : 5·03 for the remainder. The full power was 9000 indicated horse-power, the natural draught power 7000 indicated horse-power. Certain modifications were made in the arrangements of the boilers of this class, the object being to spread the wear due to steaming for auxiliary purposes over the whole of the boilers, rather than to confine it to one or two of them.

The third-class cruisers had a cylinder ratio of 1 : 4·97, the full power being 7500 indicated horse-power, and the natural draught power 4500 indicated horse-power. In the torpedo gunboats the engines were arranged as in the cruisers. The engines were of the three cylinder triple-expansion type with a cylinder ratio of 1 : 5 37, the full power being 3500 indicated horse-power, and the natural draught power 2500.

Having described the general characteristics of the machinery, some comparative remarks followed. As regarded steam-pressure it was not considered advisable to exceed 155 lb. per square inch for vessels having boilers of the water tank type. In the water-tube boilers of the Speedy a boiler pressure of 210 lb. was employed. The machinery of most of the battle-ships built under the Naval Defence Act was lighter than of corresponding vessels built previously. But in recent vessels the auxiliary machinery was considerably more powerful than in vessels of the Admiral class, and was therefore heavier, consequently the saving in weight arising from the employment of triple-expansion engines and of higher steam-pressures was even greater than the figures appeared to show. Contrasting the first-class cruisers built under the Naval Defence Act with seven tried in 1887-88, a slight increase in power per tonnage was shown at the natural draught powers which was not maintained when the forced draught powers were compared. This arose chiefly from the altered ratio between the natural draught and the forced draught in the two instances. The object aimed at in the design of the latter built vessels was to maintain a high continuous steaming power, less regard being paid to the possible performances for short periods under forced draught. The same remarks applied generally to the second-class cruisers, though in a somewhat more marked degree, the horse-power at forced draught per ton of machinery being considerably less than in the earlier vessels.

The machinery of all the battle-ships built under the Naval Defence Act was arranged in a similar manner, namely, in six separate water-tight compartments, the twin engines being abreast and the boilers being stoked athwartships. In all the cruisers the engines were arranged on a similar plan, but the boilers were in two compartments stoked in the four-and-aft direction. The valve gear in all the seventy vessels consisted of the ordinary link motion working in most cases piston slide valves in the high-pressure cylinders, either piston or flat slide valves for the intermediate, and usually flat slide valves for the low-pressure cylinders. Experience had shown that leaky boiler-tubes arose primarily from overheating due either to forced combustion or to the presence of oily or other deposits on the surface exposed to heat. This inconvenience might be mitigated (1) by interposing plate heating surface to absorb the heat before the flames impinged on the tube-plate and the tube-ends; (2) by the employment of a tube ferrule, so constructed as to prevent the flame from impinging on the tube-ends and tube-plate, and also to prevent conduction of heat to those parts by means of the air space between them and the protecting ferrule; and (3) by reducing to a minimum the oil employed for internal lubrication, and by the employment of filters or other processes for its extraction. In the Sharpshooter water-tube boilers of the Belleville type had been used. No increase of horse-power per ton had accrued, but an advantage resulted from there being no tube-ends to choke up, and the whole of the fire-side of the heating surfaces was readily cleaned when under way. Extended use of the water-tube type of boiler was being made in the torpedo-boat destroyers built and under construction. A table was given showing a few particulars of what had been accomplished with this type of boiler. Trials of the Martin system of induced draught had resulted in certain advantages in regard to the temperature of the stokeholds. Several of the vessels forming the subject of the paper had been sufficiently long in commission to have made passages at powers approaching their natural draught, and these indicated that the vessels were capable of maintaining without any special effort, and with their own complement of stokers, a high percentage of their natural draught powers.

The appendix contained the names, horse-power, weights of boilers and machinery, heating-surface, indicated horse-power per ton of machinery and boilers, indicated horse-power per square foot of grate, heating-surface per indicated horse-power, and the material of the boiler-tubes of all the vessels built under the Naval Defence Act of 1889, and to those of a similar class which immediately preceded them.

## TRACTION ENGINES AND BYE LAWS.

THE following Circular has just been issued by the National Traction Engine Owners' and Users' Association:—

> "Under the new Act, Highway Boards are abolished at any time up to December, 1897, and their duties taken over by 'District Councils.' If the 'District Council' fails to maintain and repair any highway in a good and substantial manner, the Parish Council may apply to the County Council to remedy their neglect. It is therefore important that engine owners should be represented on both the Parish Council and the District Council. Influence can then be exerted to see that the highways are maintained up to "traction engine" standard, which should be claimed to be the ordinary traffic of the district. Before taking over any highways the District Council may insist on the highways being placed in proper repair, and if they are not so done to their satisfaction, the District Council may themselves do the work and charge the expenses to the old Highway Board District. An application from a Parish Council setting out that traction engine traffic is ordinary and necessary traffic would have considerable influence. Parish Councils might also petition the County Council to modify the licence for engines. Very extensive powers for drainage and sanitary purposes are conferred on Parish and District Councils. It is therefore important to see that in any new drainage schemes the sewer and water mains are laid at a sufficient depth under the road to avoid the risk of fracture by reason of traction engines passing over. Contracting for transporting materials for repairs of roads and bridges in the immediate neighbourhood of the contractor, or supplying from his own land materials for making and repairing highways or bridges, does not disqualify from election."

The Great Western Railway Company has given the following notice:—

> "In pursuance of Section 67 of the Great Western Railway—No. 1—Act, 1884, application has been made to the Board of Trade by the Great Western Railway Company for approval of the following Bye-laws—namely: Bye-laws as to bridges over the railway (being public highways).
>
> "1. Every person who acts in contravention of Section 6 of the Locomotive Act, 1861 (which Section is as follows:—'It shall not be lawful for the owner or driver of any locomotive to drive it over any suspension bridge or over any bridge on which a conspicuous notice has been placed by the authority of the surveyor or persons liable to the repair of the bridge that the bridge is insufficient to carry weights beyond the ordinary traffic of the district, without previously obtaining the consent of the surveyor of the road or bridgemaster under whose charge such bridge shall be for the time being, or of the persons liable to the repair of such bridge; and in case such owner of the locomotive and surveyor of the road or bridge or bridgemaster shall differ in opinion as to the sufficiency of any bridge to sustain the transit of the locomotive, then the question shall be determined by an officer to be appointed on the application of either party by one of her Majesty's Principal Secretaries of State, whose certificate of sufficiency of such bridge shall entitle the owner of the locomotive to take the same over such bridge'); or of any enactment substituted for the same in the case of any bridge over the railways of the company which the company are liable to repair, shall be subject to a penalty not exceeding five pounds for every offence.
>
> "2. No engine, machine, vehicle, or article of traffic weighing—inclusive of any load, matter, or thing carried or resting thereon—more than five tons, or carrying—inclusive as aforesaid—a greater weight than two tons on any one pair of wheels, or drawing a weight of more than four tons, shall be taken upon or across the bridge, being a public highway, over the railways of a company, on or near which a notice to the effect that such bridge is unsafe for heavy traffic is for the time being affixed or published.
>
> "Every person who takes or sends any such engine, machine, vehicle, or article of traffic upon or across any such bridge as aforesaid in contravention of this bye-law shall be subject to a penalty not exceeding £5 for every offence.
>
> "This bye-law does not extend to locomotive engines, to which the preceding bye-law extends."

The bye-law would, it appears, prevent the Great Western Railway from being crossed overhead by any bridge the property of the company, and it is more than likely that the example thus set may be extensively followed by other railway companies throughout the kingdom.

---

AT a recent meeting of the Berlin Meteorological Society, Dr. Schwalbe spoke of his endeavours to utilise for scientific purposes the curves of temperature obtained from the "Uranus" pillars. He found among the many meteorological pillars in Berlin which had given continuous records during the years 1892 and 1893, very few whose readings corresponded with those of control instruments. Taking the month of July for each year, he had endeavoured to arrive at the mean daily temperature by taking the mean of the temperatures registered every hour of each day in the month. He found this mean temperature to lie between the values of the expressions $(6 + 2 + 10) \div 3$ and $(7 + 2 + 9 + 9) \div 4$.

## RAILWAY MATTERS.

The electric underground railway at Budapest will be two miles long. The line is to be completed by April 1st, 1896.

The Prussian State Railroads in 1892 had in their service an average of 188,958 workmen entitled to insurance payments in case of accident. The payments to these men for insurance amounted to 411,552 dols., which is equal to 2·18 dols. per employé. The year before these payments had been at the rate of 1·70 dols. per man.

The London Chamber of Commerce, in response to the invitation from the Board of Trade, have nominated Sir Edward H. Carbutt, Bart., chairman of the Engineering and Allied Trades' Section, and Mr. Emil Garcke, chairman of the Electrical and Allied Trades' Section, as the delegates of the Chamber to the conference on light railways, which is to meet early next month.

The first section of the Salonica-Constantinople Railway, 54¾ miles in length, and having six stations—Salonica, Salmanbi, Sariguerri, Kilindir, Karasouli, and Dairan—has been completed and opened for general traffic. There will be one train each way daily, running the distance in 5 hours 35 minutes, including stoppages. The construction of the next section—Dairan to Serres—about 62¼ miles in length, will be completed in December.

We are not alone in our sufferings from inundation. In consequence of recent rains, the railway service between Genoa and Ventimiglia has been completely interrupted for some hours, a tunnel between Voltri and Arenzano having been flooded. Communication has been, however, restored. In many places shops and cellars were submerged, while the railway station at Santa Limmiana was invaded by the water, which rose at some points to a height of 3ft.

In defending the administration of the French railways, M. Barthom, the Minister of Public Works, on the 18th inst. said England alone attained greater security for its railway travellers. Speaking of the hours of labour on the railways, he mentioned that they had now been fixed as far as possible, and those of station-masters so arranged that they will in future get eight hours' rest. That is sixteen hours of responsible activity per day, or double the number that our Board of Trade inspectors, or some of them, consider proper for even the inferior servants of our companies.

A report has been presented to the Board of Trade by Major-General Hutchinson, on an accident which occurred on the 14th July, on the Swansea and Mumbles Railway, when as a train was proceeding at a slow rate of speed along the side of one of the streets in Swansea, a young female child, about 2½ years old, suddenly ran out on to the line through the opening between the railing and the end of the school building, just after the engine had passed, was caught by a rear vehicle, and had one of her legs so severely injured that it had to be amputated. Major-General Hutchinson, even in this case, manages to get in some demands for shorter hours, the total number being nine, just because a youngster suddenly gets through a railway fence, and after the engine has passed, gets itself caught by the train. Because of this, the hours of drivers and stokers are to be reduced, presumably so that they may have spare energy to watch the sides of the train as well as the road in front of them. "The hours of duty of drivers and firemen on this railway—twelve in the present case, with seven or eight intervals of rest of twenty-five minutes each are too long, and the company should, I submit, be called upon to reduce these hours."

Amongst the private Bills in Parliament, Session 1895, the preamble of that of the North British Railway is rather a heavy one, and involves the construction, deviation, or alteration of no less than fifteen lines. New railways and works are projected in its own county and in the adjacent one of Chester, by the North Staffordshire Railway, and the "Taff Vale" is, as usual, also a petitioner. The Glasgow and South-Western, the Lynton, the Midland, and the Lancashire and Yorkshire are also in the field, and a new company seeks to be incorporated under the title of the Neath, Pontardawe and Bryn-Aman Railway, for the construction of new lines in the county of Glamorgan. It may be mentioned that notice has been issued under the head Metropolitan Outer Circle Railway, for the abandonment of railway, release of deposit, winding up and dissolution of company. Bristol and Bridlington both seek for powers in connection with waterworks, the Ambleside Local Board adds gas to similar provisions, and York, Whitby, and Felixstowe may be included in the same category. The North Middlesex, Newmarket, and the South Metropolitan petition only for gas lighting powers. Board of Trade: For Provisional Orders of electric lighting, we find the Bootle Corporation, and the Liverpool Electric Supply Company.

Some additional particulars are now to hand with regard to the proposed second Simplon Tunnel, which will be of interest. As soon as it was known that the Swiss authorities had decided in favour of the enterprise, a mixed firm of German and Swiss contractors met in conclave to consider the question of submitting a tender for the great work of tunnelling under the Alps. The estimate was the first question, and the result of their deliberations was to prepare and submit one, which completely threw into the shade all the others that had previously been put forward. The difference was twofold, relating both to the time required for the execution of the work and the amount of the total cost. To start with, the cost of the plant, machinery, and appliances is valued at rather more than half a million sterling. In commencing the tunnel, which will be worked from both extremities, only one line of track will be proceeded with, but at the centre the width will be enlarged, so as to allow room for a bye-pass. For this part of the work a sum of £1,900,000 is demanded, which is at the rate of £110 per yard run. Should the company determine to make it a double track tunnel, it binds itself to give the order, before the expiration of the first four years of work, and to pay an extra £600,000, on condition of being put into possession four years after the giving of the order. The total cost of a double track will thus amount to £2,500,000, which will allow £145 per lineal yard.

In concluding a report on the accident which occurred on the 5th September, at Towyn station on the Cambrian Railways, Lieut-Col. H. A. York says:—"This accident must be attributed to the fact that the facing-points at the south end of the loop line were not properly closed when the engine of the down train reached them. The result being, as already stated, that the engine and tender, and six out of eight vehicles composing the train left the rails, and ran along the ballast for about forty yards before coming to a stand." No passengers were injured or even complained. The labour leader style of remark completes this report. The total number of hours of men on duty being the basis for more complaints. In this case there seems to have been rather more work for one of the porters than he could always get through, but no allowance is made in these complaints for the hours in the day when there is little work in hand, when there is practically a resting time. Common fairness, however, forces the Board of Trade Inspector to point out that the station master's hours must be proportionately long, by which he probably means that they are longer than those of the porters. The usual request that the company shall alter these hours is made, as well as suggestions as to signalling and locking arrangements which are already in hand. It is not, however, admitted that the completion of these arrangements will relieve one at least of two porters referred to from the work which now much interferes with their ordinary duties. It is something, perhaps, that the Board of Trade Inspector does not ask the railway company to appoint two station masters because the hours are too long.

## NOTES AND MEMORANDA.

In Brooklyn the use of cement pipe for sewers in preference to vitrified still continues. This is due in a measure to the smaller sizes of cement pipe being less expensive than the corresponding sizes of vitrified pipe.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 17·1 per 1000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year. The rates varied from 10·7 at Leicester to 26·3 at Newcastle-on-Tyne.

M. Henri Moissan has recently read another paper before the Paris Academy of Sciences on "The Evaporisation of Carbon." The heat of the electric furnace enables carbon to be volatilised; the sublimed carbon is always deposited under the form of graphite at ordinary pressures, and there is no evidence whatever of the liquefaction of the carbon; for instance, the lid of a carbon crucible did not adhere when the whole mass had been converted into graphite, and a carbon needle heated in a carbon tube did not in any case become attached to the latter. *Nature* points out that previous experiments have, however, shown that under great pressures carbon may be fused, and diamond is then formed.

In contrast to the very large generators of electricity—batteries and dynamo-electric machinery—in such common use to-day, it may be interesting to note what is perhaps the smallest electric battery ever constructed, and no doubt also the smallest generator of electrical or mechanical energy. This battery was constructed some years ago by one of the electricians of the Boston Telephone Company, and consisted of an ordinary glass bead, through which two wires, one of copper and the other of iron, were looped and twisted so as to prevent their coming in contact. The wires acted as the electrodes, and all that was necessary to cause a current to flow was to place a drop of acidulated water in the bead. Certainly such a minute battery furnished but an infinitesimal current, but could be easily used in a delicate telephone, and, according to *Cassier's Magazine*, it is said to have actually been used in signalling to a distance of nearly 200 miles.

In a letter to a contemporary on the floods in the Thames Valley, Mr. F. C. Clutterbuck gives some figures in comparison of this flood with the great floods of this century. "Its height, of course, will differ locally. The data given are from memorandum in my possession made by my father, the Rev. J. C. Clutterbuck, vicar of Long Wittenham, Berks, from 1830—1885, who was a careful observer of these matters, and also a careful collector of evidence of bygone years. The greatest floods of this century are 1809, 1821, 1852, 1875, and the present year 1894. From these memoranda, and from my own observation this year, these floods were the following measurements above navigation high-water mark:—1809, 9ft. 1in.; 1821, 8ft. 10in.; 1852, 7ft. 10in.; 1875, 8ft. 1in.; 1894, 8ft. 8in. The flood this year was caused by heavy rains, from 4in. to nearly 5in., in this district from 8 p.m. on November 11th to 8 p.m. on November 14th, there being 24 hours out of the 72 without rain. It is a curious coincidence that the three floods of 1852, 1875, and 1894 were at their height within a few hours of each other on November 15th and 16th."

In the report on the composition and quality of daily samples of the water supplied to London, for the month ending October 31st, 1894, Mr. William Crookes, F.R.S., and Professor Dewar, F.R.S., say:—The rainfall during the month at Oxford, representing the Thames Valley, has been 3·97in., and as the twenty-five years' mean for the month is 2·56in., it follows that there has been an excess of rain amounting to 1·41in. Most of the rain fell at the latter part of the month, no less than 3·27in. falling on five days, the 24th, 26th, 27th, 28th, and 30th, the rest of the month only having 0·7in. of rain. The effect of so much sudden downpour was to wash a certain amount of clay into the river and cause discolouration. Analysis shows that the turbidity is not caused by excessive organic impurity, but by purely inorganic and harmless matter. The Grand Junction waters, as well as those of the other companies, were practically free from microbes, and in the least clear sample of water drawn from the stand pipe at Shepherd's Bush into a sterilised tube, there was detected only twenty colonies per cubic centimetre after cultivation for forty-eight hours in nutritive gelatine.

Mr. G. J. Symons has contributed to Part II. of the Report of the Chicago Meteorological Congress an interesting summary of early English meteorological literature, embracing the years 1337-1699. He only deals with some fifty books and pamphlets contained in his own library, but his special knowledge of meteorological bibliography enables him to give some useful particulars about these old works. We can only briefly refer to a few of them here. In the Bodleian Library at Oxford there is—as far as is known—the earliest continuous weather record in in the world, containing observations by one W. Merle from January, 1337, to January, 1344. A few copies of a translation of this work were printed in 1891. These observations show that the weather at that time was very similar to what it is now. In 1670, "The Shepheard's Legacy" was printed. This work is excessively scarce, and is the earliest edition of what has since been reprinted many times as "The Shepherd of Banbury's Rules for Judging the Weather." In 1671 appeared "A Discourse concerning the Origine and Properties of Wind," &c. This treatise is noteworthy as being probably the first in which the theories of the winds are compared with details of the trade winds, monsoons, &c. In 1696 a work entitled "New Observations on the Natural History of the World of Matter," &c., by the Rev. T. Robinson, was published. It gives the earliest description yet known of the strong local wind known in Cumberland as the helm wind.

At the last meeting of the Physical Society a paper was read by Dr. J. Larmor on "The Significance of Wiener's Localisation of the Photographic Action of Stationary Light Waves." The experiments by which Wiener demonstrated that when stationary plane-polarised optical undulations are produced in a photographic film, by reflexion of a stream of plane-polarised light at a metallic or other backing, the photographic action occurs at the antinodes of Fresnel's vibration vector and not at the nodes, have been employed by its author and others to decide between the various theories of light. Using the terminology of the electric theory of light, we may say that the photographic action takes place at the antinodes of the electric vector, which corresponds to Fresnel's vibration, and not at the intermediate antinodes of the magnetic vector, which corresponds to McCullagh's and to Neumann's vibration. The crucial experiment of Wiener relates to the case when the angle of incidence is 45 deg., so that the direct and reflected waves which interfere are at right angles to each other. When the light was polarised in the plane of incidence, the photographic plane developed a series of bands; but when it was polarised in the perpendicular plane, these bands were absent. The argument employed is that the photographic effect will be greatest at those places in the stationary wave train where the vibration is most intense; and the conclusion has been drawn from it that the actual vibration is represented by Fresnel's vector and not by McCullagh's; in other words, that the vibrations of polarised light are at right angles to the plane of polarisation. The force of this argument, as against McCullagh's theory, would, however, be evaded if the vector of that theory were taken to represent something different from the linear displacement of the ether, or if vibrations were excited in the molecule by rotation instead of translation, or by stress. Now there are about $10^3$ molecules of the sensitive medium in the length of a single wave of light—thus in the stationary wave train all the parts of a single molecule would at any instant be moving with a sensibly uniform velocity, which increases and diminishes periodically. It does not seem clear, however, that alternating stress might not be as potent a factor in disintegration as alternating motion.

## MISCELLANEA.

In a recent number of the *Comptes Rendus* is a paper on "The Relations between the Vapour Pressures of a Body in the Solid and in the Liquid State: Influence of Pressure on the Temperature of Fusion," by M. A. Ponsot.

Several of the small torpedo boats intended for the depôt ship Foudre have now been delivered to the French naval authorities. "A" is 62ft. 4in. long, 14¼ tons displacement, 210-horse power, giving her a speed of 16·3 knots. Only one of the Foudre's boats is built of aluminium, being that recently supplied by Messrs. Yarrow and Co.

The unsatisfactory results which persistently attended the trials of the Halcyon, gunboat, have been traced to the improper plating of her under parts, which were out of line owing to the inability of the Devonport Dockyard hands to do the work under test measurement. A remedy is now being applied by sheathing the bottom with wood—an expensive undertaking. Test measurement will be discontinued for the present.

The Union Steamship Company's twin screw Royal mail steamer Norman, which left Southampton on Saturday, November 10th, with the outward Cape of Good Hope and Natal mails, arrived at Madeira at 5.0 p.m. on Wednesday, November 14th, and proceeded for Cape Town at 7.0 p.m. Passage, 3 days 10 hours, net steaming time. Average speed, 15·6 knots per hour. Experienced very heavy weather, steaming slow for twelve hours.

At a meeting of the cement trade held at the London Chamber of Commerce on Tuesday last, it was resolved—"That a committee be appointed, with power to engage experts to investigate into the question of the admixture of Kentish Rag Stone, other stone or other material with Portland cement, so far as carried on at home and on the Continent, and to report and advise thereon." Representatives of eleven firms were appointed upon the committee. The formation of a Cement Manufacturers Association, with the object of stopping adulteration, was reported in our last impression.

A little steamer of a hundred tons is at present, according to a Dalziel telegram, being constructed at Argenteuil according to the invention of M. Bazin, which consists in rolling the ship over the water instead of forcing it through as at present. To this end a number of enormous copper cylinders are fixed to the vessel, the speed attained depending upon the speed of the metal cylinders, and it is computed that 31 knots an hour can be easily made. The steering is done by a kind of hydraulic pump, and an advantage claimed is that no way is lost in altering the course. It is hoped the vessel will be built without much loss of time. The trial trip will be made between Dieppe and Newhaven.

The Champagnac Collieries, situated in the communes of Champagnac, Ydes and Bassignac, Arrondissement of Mauriac, in the French Department of Cantal, with the concessions of Bort and Sarroux in the Arrondissement of Ussel, Corrèze, are announced for sale by auction on the 9th of November at the upset price of one million francs—£40,000. The property in question comprises the mine concession, surface property, houses and other buildings, washing floor and briquette works, plant, tools, and machinery, now belonging to the Société Rougier, Pochat et Cie. The stocks, stores, change parts of machinery, &c., are to be taken at a valuation, and possession will be given on completion of the purchase. Full particulars may be obtained from M. Perlia, engineer, liquidator of the above-named company at the colliery.

Last year a fifth blast furnace, of larger dimensions than the four already existing at Pont-à-Mousson, in Meurthe-et-Moselle, was, as reported by the *Revue Industrielle de L'Est*, completed and blown in. Last February one of the old furnaces was blown out, pulled down, rebuilt on the new lines, and blown in four months later, when a second furnace was blown out, pulled down, and reconstructed to the same scale for immediate blowing in, these two new furnaces being provided with Cawper stoves 30 m. (98ft.) high. The two old furnaces still remaining are to be reconstructed next year, so as to bring the total daily out-turn at Pont-à-Mousson to 300 tons. It appears that this quantity will be rather in excess of local requirements, so that when the furnaces are at full production some grey pig will be in the market.

The Gainsborough Local Board of Health have now received the sanction of the Local Government Board to a loan of £5750 for their proposed new boring. This boring will be somewhat remarkable on account of its great diameter and depth. It is to be 1450ft. deep, and not less than 18in. diameter in the sandstone, and will take the best part of two years in execution. The whole scheme, as designed by Mr. Jabez Church, M.I.C.E.—see The Engineer of July 6th, 1894, page 4—has been approved by the Local Government Board, and as soon as the new boring is sufficiently advanced to confirm the engineer's opinion as regards the quantity of water to be obtained from it, the remainder of the amount appliedfor will be at once sanctioned in order to complete the scheme. As regards the probable success of the new borehole, it will be situated only a few yards from the one now supplying the whole of the water required by the town, and will be carried 600ft. lower than this, and 18in. instead of 10in. minimum diameter. Consequently there cannot be any doubt but that the new supply will prove ample for the needs of the town for many years to come.

During the course of the inquiry into the cause of the electrical accident at Cannon-street, Mr. David Cook, chief engineer and manager to the City of London Electric Lighting Company, said the primary cause of the accident was the crossing of two high-pressure cables, which were being tested, and put to work for the first time. One of these cables was for the supply of current to the Watling-street transformer station, and the other for the Milk-street transformer station. The Milk-street cable was inadvertently put into the Watling-street terminals at Bankside, while the Watling-street cable was laid with its inner conductor touching the lead covering of a third cable. For convenience the Watling-street cable was made alive by current from the transformer station. When the signal was given, the man at the transformer station switched on. The inner of the conductor was against the lead covering of another cable; therefore, the inner of the whole high-pressure system was put to earth, throwing an unusual strain upon the insulation of the primary mains. The cause of the breakdown appeared to have been due to a mechanical abrasion of the outside covering, and the leak in the junction-box developed into a short circuit, thus firing some gas which was in the conduit, and blew up the cover of the box. He should propose to his directors at their next meeting to provide a complete system of ventilation of conduits at a cost of some £2000. Major Cardew said the Electric Light Company came after the Gas Company, and their regulations required them to keep their conduits free from gas. Mr. G. F. L. Foulger, chief distributing engineer of the Gas Light and Coke Company, said he thought the scheme of ventilation suggested by Mr. Cook would be a very bad one. He considered that if the Electric Lighting Company used their arc lamp-posts, which were 20ft. high, and if they were to fill them up with earth or sawdust to prevent the gas firing back, and carried, say, a 1½in. or 2in. pipe as a ventilating pipe, with an outlet to the atmosphere of about one-half the height of the post, then there would be no danger whatever of the gas firing back from the arc light through 10ft. of atmosphere. The earth need not go right through the column. The ventilating pipe ought to be about 10ft. high, so as to be beyond the reach of passers by.

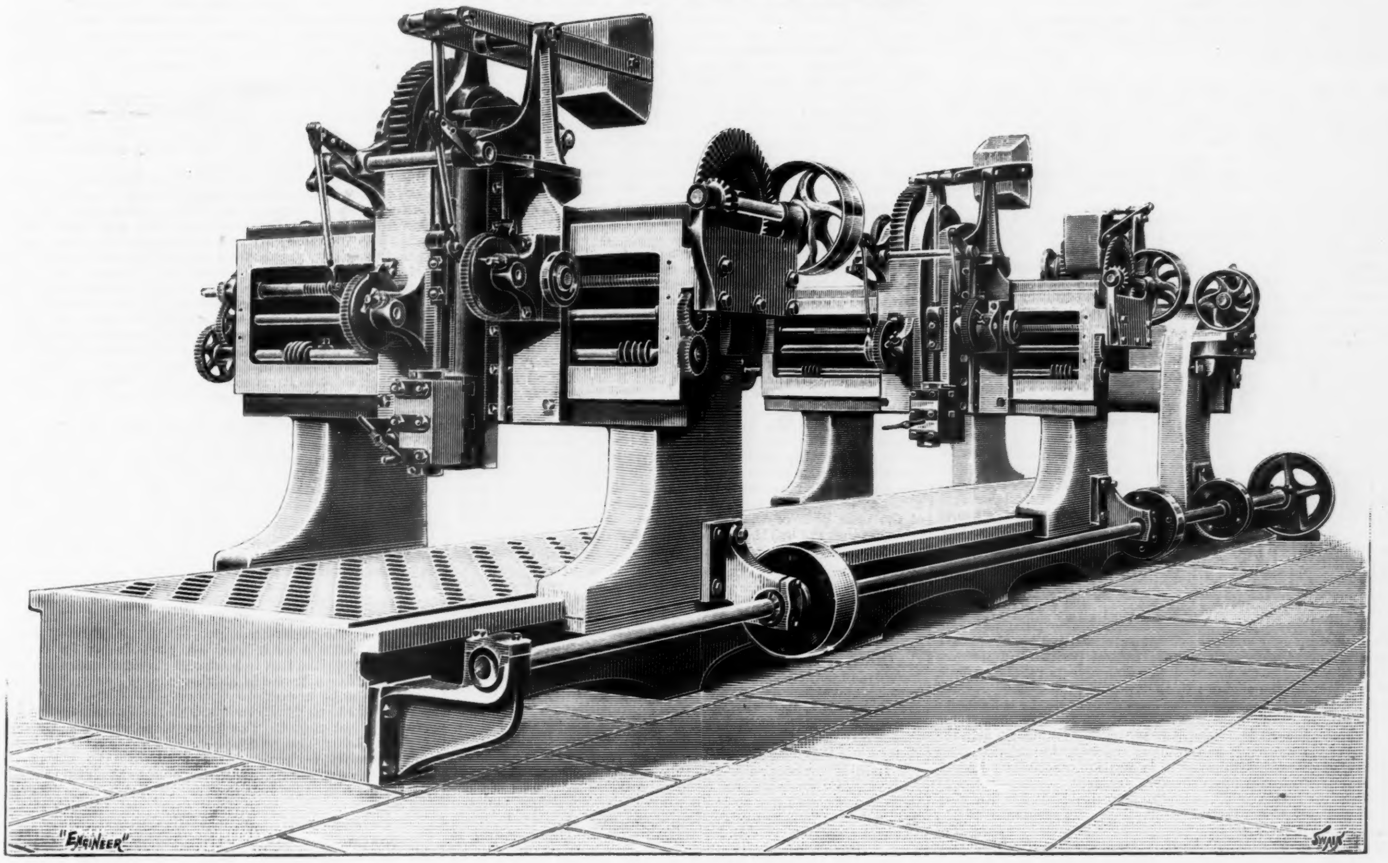
# LOCOMOTIVE FRAME-PLATE SLOTTING MACHINE

MESSRS. CRAVEN BROTHERS, MANCHESTER, ENGINEERS

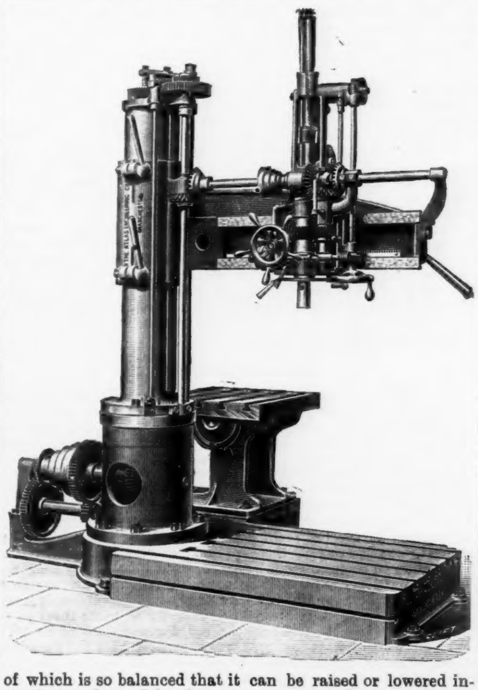


## LOCOMOTIVE FRAME-PLATE SLOTTING MACHINE.

DURING a recent visit to the Vulcan Foundry Company, Newton-le-Willows, near Manchester, we noticed amongst new plant that had been put down in connection with the extension of its locomotive works, a specially designed frame-plate slotting machine, made by Messrs. Craven Brothers, of Manchester, containing several new features, a brief description of which will be interesting. The accompanying illustration shows the general arrangement of the machine, which has a massive bed 36ft. long, admitting plates 5ft. wide, and there are three heads, each with a ram having an adjustable stroke up to 15in. deep. The heads, which are all identical in construction—so that the following description applies to each—can be worked all together or stopped and started separately, and the self-acting feed motions are self-contained on each carriage, thus enabling each head to work independently, or the three heads can be operated all together. The self-acting feed motions are timed to feed before the cutting tool starts at the top of stroke, and the feed is regulated for fine or deep cuts, this being effected by a circular plate alongside the catch wheels. This plate is arranged with part of its circumference the full diameter to the top of the catch-wheel teeth, and the outer part of its circumference to the same diameter as the bottom of the teeth, and the plate is regulated in position by a small worm-wheel motion to allow the feed-catch to ride on the full diameter or on the smaller diameter, so as to shield or expose the teeth in the catch-wheel to the action of the catch. The plate can thus be regulated to allow the catch to take one tooth or many without altering the position of the studs in the levers. Two self-acting feed motions are provided on each head, one for the longitudinal, and the other for cross traverse motions of the cutting tool. When it is required to slot the horns of locomotive framing taper, there is an arrangement by which the longitudinal and cross traverse motions are in gear at the same time, and by means of change wheels various tapers can be slotted self-acting, the cutting rams being thus enabled to slot parallel or at right angles to the bed or taper. The cutting rams are worked first by a shaft the full length of the bed, having a key groove its full length, with a large three-speeded cone pulley at the driving end, and three broad pulleys, one for each head. These pulleys have a long boss working in a collar bearing on each head, and moving with the head; the boss is fitted with a long steel key working in the key groove in the long shaft, and each of the three broad pulleys drives a pair of fast and loose pulleys on the heads, whilst a strap-lever arrangement is provided at the front side of the machine to enable the workmen to transfer the driving belts to the fast or loose pulley to start or stop each head. The pulleys on the head drive a pinion working into a large bevel wheel upon a shaft; this shaft has a pinion with a steel key in the boss working in the key groove in the shaft, and the pinion works in a bearing on the carriage, and drives a large spur wheel on a shaft with a forged steel disc at one end. This shaft runs in two bearings, the driving wheel being between the two, the disc being supported in a bearing at its outer diameter and made with a planed slot across it, and fitted with a strong stud or crank pin, which is altered in its position on the disc by a screw to regulate the length of the stroke, and when adjusted is secured to the disc by a large nut. The stud or crank pin is provided with a hardened steel block which works into a hardened steel vibrating link on a fixed stud on the carriage at one end, and a connecting-rod at the other connected to the cutting ram, which is raised at a quick speed in the up-stroke and slower at a uniform speed in the cutting or down stroke, and the position of the ram is variable to suit the height or thickness of the work to be slotted. The bottom end of the ram is provided with a tool-holder which can be rotated by a worm-wheel motion for slotting curves, and the ram is balanced by a weight and levers to facilitate the quick return motion and relieve the strain on the crank disc and link.

## UNIVERSAL RADIAL DRILLING MACHINE.

THE engraving below illustrates a new radial arm drilling machine made by the Atlas Engineering Company, of Levenshulme, Manchester, and containing several features of interest. It is a 4ft. radial drilling machine, the radial arm of which is so balanced that it can be raised or lowered instantaneously, and for the same reason can be swung round very easily, the balance being inside the vertical column. The machine will admit a piece of work 5ft. high between the spindle and base plate, or can be lowered until the spindle is within 9in. of the base. The apparatus for raising or lowering the arm is very simple, and is operated by the lever shown at the bottom of the pillars. The pillar is made sufficiently strong to withstand the strain of heavy drilling, when the carriage is at the end of the arm. The spindle is 2¼in. diameter, runs long bearings, and has a self-acting feed of 15in. It is provided with a quick release and return motion, being balanced by a flat coiled spring. The spindle is also reversible for tapping by means of the clutch bevel gear shown, the lever for this purpose being placed in a convenient position beneath the carriage. The gearing is all machine-cut, the smaller pinions and racks being in steel. A convenient counting table for angular work is fitted to an off-set from the bed-plate. This table has a top 30in. by 30in., with T grooves. It can be set at any angle from a horizontal to a vertical, one side being indexed in degrees for the purpose of setting work easily to the required angle.

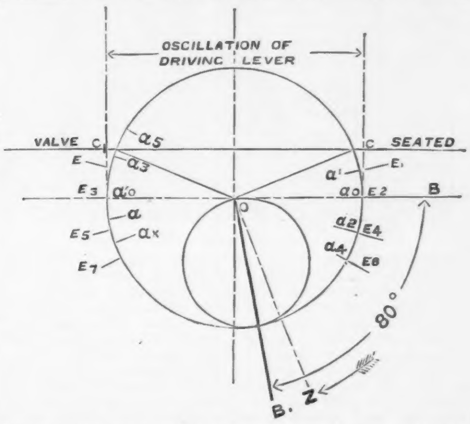


## LETTERS TO THE EDITOR.

*We do not hold ourselves responsible for the opinions of our correspondents.)*

### GOVERNING ELECTRIC LIGHT ENGINES.

SIR,—Allow me briefly to reply to Mr. Dunlop. In regard to his relating to mine of 29th ult., I do not consider it calls for any reply, but I shall be glad of a little of your valuable space to endeavour to show what, practically, this discovery of your correspondent amounts to—which thing, by the way, has been known for years to those who have had any experience with this type of gear, which it is very evident that Mr. Dunlop has not had. In practice the negative angle of advance is 80 deg., and the diagrammatic sketch herewith enclosed will, I think, more clearly show than the one invented by him the mare's-nest he has discovered.



The circle represents the total oscillation of the driving lever. The lines inside the circle denote some of the positions of the angle lever or bell crank edges, those outside the positions of the detent latch or lifter edges. When in mid-position, and the detents are not gearing with the angle lever faces, the detent faces are at C $C_1$, whilst those of the angle lever are at $A_0$ $A_0$, the valve being closed. Suppose the excentric to be moved back until it lies on the line O Z when the active edge of the angle lever will be at C, the idle edge being at A X, the detent faces remaining at $C_1$ C. On the excentric moving to $B_1$ the active edges of the lever and detent will be at $A_1$ $E_1$, which is zero, and the valve will be open by the amount C E, the idle edges of the lever and detent being at A and E respectively. If release occurred, there is nothing to prevent the edge of the latch arriving at C when the valve is seated. On the arrival of the angle lever edges at $A_0$ $A_0$, the active face of the detent is at $E_2$, the idle face being at $E_3$; it is possible, but problematical, that if the edges be released the valve might be arrested here, but, as the governor has lifted the active edge clear, it will have placed the idle edge in the same position, the point $E_2$ to $\frac{1}{64}$th cut-off. On the angle lever edge arriving at $A_2$, which corresponds to $\frac{1}{16}$th cut-off, the idle edges of the lever and detent are at $A_3$ and $E_5$ respectively; on release, the idle edge of the detent would strike the idle edge of the lever at $A_3$, and the valve would not be closed by the amount $C_1$ $A_3$—in reality it will be less, as the edge $A_3$ is not stationary. When the lever edge arrives at $A_4$ = one-eighth cut-off, the idle edge of the lever is at $A_5$ and that of the detent is at $E_7$; on release, the valve seats at the idle edge of the lever is above $C_1$. The interval in which arrestment of the valve is from $A_0$ to $A_3$, a matter of less than 5 per cent. of the total range, viz., from zero to five-eighths, which is ample for a compound engine. Mr. Dunlop will probably now see the reason why the loose bridle has not been brought forward sooner, the arrestment being of no practical importance. I consider it only necessary in special cases.

I am afraid your correspondent will require to look elsewhere for the cause of the ineffectual governing of electric light engines.

Maryport, November 19th. WM. CAMERON.

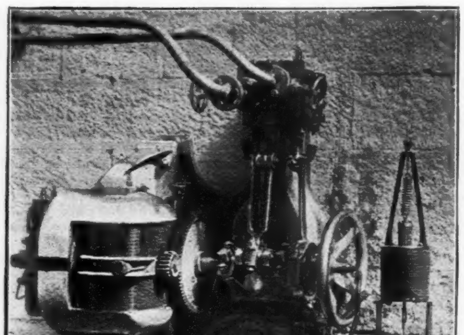
---

SIR,—I have followed with very great interest the correspondence in your paper regarding governors for steam dynamos, and judging from the various opinions expressed therein, it seems to me that the gentlemen who have been discussing this question are on a false track, or do not seem to understand the matter thoroughly. There is no doubt that the governing of electric light engines is still in its infancy, and a very arduous problem not as yet solved.

The difficulty of governing the speed of steam engines, and especially on board ship, is very great, and up to the present the real effective governor has been a fireman, who is placed at the throttle valve to open and close the stop valve, so that a constant current as near as possible may be kept. Naturally this form of governor is rather expensive. The call on a governor for electric light on board ship is far greater than for land installations. The durability of the lamps depends principally on the regularity of the electric current. It is therefore a great boon to have an electric governor; moreover, a constant current of electricity is not only economical, but at the same time it produces a steadier light.

I have lately had the satisfaction of overcoming the difficulty, and have been able to keep a constant voltage by using a fluid regulator. The type of centrifugal governors keyed on the shaft, and other systems offered in the trade, are not employable, for they only begin to govern after the engine has arrived at an irregular speed, and the existent governors which are efficient in this respect are so very delicate that they cannot stand the strain of hard work demanded from them. For instance, a Swiss firm produce a very good governor, but its great fault is that it has to to be taken to pieces every fortnight to be cleaned and adjusted, thus making it impracticable on board ship. I have, jointly with Mr. David Joy, patented a governor, which has been fitted to four different electric light installations; the results obtained are equal to all demands. The principle of this governor is as follows: On the crank shaft of the engine there is placed an excentric of Mr. Joy's patent oil gear type, the sheave having plungers which are actuated upon by hydraulic oil pressure, which gives the sheave a variation of excentricity from the central position to full throw of the excentric. The throw of the excentric is regulated by a pump, driven by the engine; this pump sucks the oil from a small receiver, inside of which the governing valve is placed; if the valve is opened, the pump sucks the oil out of the receiver, but if the valve closes, the oil is forced through another opening into the plunger of the excentric sheave, thus reducing the travel of the slide valve. The governing of this valve is effected by an iron core, which is placed inside a solenoid.

The various functions take place as follows:—Through the closing off of a part of the incandescent lamps, the resistance of the main current is increased; consequently the voltage rises. The solenoid being intercalated in the current, draws the iron core downwards, and reduces the valve opening to which it is attached. The oil pumped into the valve cannot return, and is driven into the plunger, which in turn reduces the travel of the slide valve, and giving an earlier cut-off. This diminishes the revolutions of engines and gives a constant voltage.



In the installations carried out by us we have found that 40 per cent. of the incandescent lamps may be turned off without increasing the voltage. At the moment of interruption there is only a very slight increase of voltage visible, which disappears instantly through the rapid action of the governor, and with a greatly diminished number of incandescent lamps the voltmeter shows a lower rather than a higher pressure, which is all one can wish for.

The sensibility of the governor can be regulated by a set screw so as to keep whatever pressure is required, and the engine will constantly keep the same revolutions. The governing has been also tried on a generating engine of a central station for the transmission of electromotive power, and also in this case gave favourable results. The motor dynamos were stopped and started, and the voltage of the generator almost kept constant for all practical purposes. With this system I believe to have found the proper way of governing efficiently electric light engines, and have also used a sound principle. The obtained favourable results will amply prove this statement.

F. KADVEITSCH, Managing Director.
Austrian Lloyd's Steam Navigation Company,
Trieste, November 17th.

## THE THEORY OF THE STEAM ENGINE.

SIR,—I cordially agree with much that Mr. Maurice Cross has stated in his letter, dated November 12th; but disagree, *toto cœlo*, with his views about the results of the activity of Maxwell's little demons. In the case of steam engines, the actual results certainly exceed the efficiency represented by the ratio $\frac{T-t}{T}$, if the value of this is calculated on the assumption that equal increments of volume correspond with equal increments of heat, and the absolute temperature of melting ice is assumed to be equal to the difference between the temperatures of melting ice and boiling water, divided by the coefficient of expansion of volume between the two temperatures. If the coefficient of expansion per increment of unit of heat is constant, we have, on the assumption stated for temperatures on the constant coefficient scale, $\frac{T-t}{T} = \frac{a}{a}$. I have, however, demonstrated—and no one has been able to point out any flaw in the demonstration—that the Carnot cycle cannot be carried out in the way described by Carnot, if Carnot's own theory is true; and that, if heat and work are convertible, the ratio $\frac{T-t}{T}$ deduced from the direct Carnot cycle has nothing to do with the efficiency of a heat engine, and has no place in the science of thermodynamics. The reverse Carnot cycle is an impossibility, if heat cannot be transmitted by conduction from a cold to a hot body. The direct Carnot cycle is an excellent graphic illustration of the convertibility of heat and work in isothermal compression and expansion, but it is nothing more.

If Mr. Maurice Cross believes in the principle of the convertibility of heat and work, how can he—consistently with this belief—affirm that the work done by Maxwell's little demons in punching each other's heads, blacking each other's eyes, and throwing about limbs and tails, does not generate heat? I have demonstrated that the increased efficiency of high-pressure compound engines is principally due to the partial utilisation of the so-called latent heat caused by the motions of these little demons—in sober language, the molecules of steam. Can Mr. Cross point out any flaw in the demonstration? When heat is received by a liquid or gas, molecular motion instantaneously takes place, and continues as long as the liquid or gas continues to receive heat. As soon as heat ceases to be received or given out the molecular motion is gradually destroyed by molecular friction, and as soon as such molecule attains the same common temperature, intermolecular motion ceases, and every molecule of the body remains at rest. Molecular *vis viva* is the cause of heat, heat is the cause of molecular *vis viva*; but molecular *vis viva* is not a form of heat. In the phrase, "motion is a form of heat," by the term motion *vis viva* must be meant. When heat is applied to one part of a solid body no intermolecular motion is produced. The heat is transmitted from one part of the body to the other wholly by radiation, none by molecular convection.

In the case of the gas engines, the greater the fall of the temperature in the cylinder, the less the amount of the waste heat which passes up the chimney. How does Mr. Cross reconcile his belief in the principle of the convertibility of heat and work with his belief that the less the fall in the temperature the greater is the efficiency of the gas engine, if that efficiency is estimated in terms of the total heat of the operative substance? It is extremely probable that the less the temperature of the explosion the greater the efficiency. Do gas and air combine chemically in varying proportions?

Professor Alexander rightly dissents from the theory that in the perfect heat engine the heat must be received at a constant temperature and given out at a constant temperature. He states that he has proved this to be true by proving that the cycle in Sterling's air engine, where the temperatures vary, is as perfect as the Carnot cycle. I cannot admit the validity of the proof, as I have demonstrated that the Carnot cycle has nothing to do with heat engines of any description; but surely the falsity of the theory is self evident. How can the nature, properties, or mechanical powers of the heat received depend upon the temperature of the source of heat? In the extract from the work of Clausius units of heat are described as being of varying temperatures. What in the name of common sense can a unit of heat, *i.e.*, a number of foot-pounds, have to do with temperatures? The number of units of heat possessed by a unit of Carnot's heat substance varies in accordance with Carnot's definition as the absolute temperature of the heat substance, so that the mechanical work corresponding to a fall of $T - t$ degrees varies as $\frac{T-t}{T}$, but this has nothing to do with the Carnot cycle. It follows at once from Carnot's definition.

It seems almost incredible that Professor Smith should have affirmed that the abstraction of heat from a body in tension increases its mechanical power. The statement is a flat contradiction of the truth of the principle of the convertibility of heat and work. The tension is increased, and if it is sufficiently increased to overcome the forces which keep it in tension, these forces will be drawn towards each other until they again become equal to the tension. The total loss of mechanical power by the body in tension will be equal to the sum of the work done in drawing the resisting forces towards each other plus the equivalent of the heat abstracted by the conduction. Professor Smith seems to be in this case in the same "quandary" as one of your correspondents, who could not understand why a given weight of gas compressed up to a given pressure by adiabatic compression should have more power to do work than the same weight of gas compressed to the same pressure isothermally, the temperatures before compression being in each case the same. Professor Smith states that Carnot's theorem represents the "mathematical demonstration of an all-important law in thermodynamics." Will he kindly explain how a theorem can represent a demonstration, and describe the all-important law demonstrated?

I have demonstrated that under no possible condition can a gas expand without doing work, and have given several illustrations of the truth of this statement. Can "Lex" evolve out of the depth of his own inner consciousness an imaginary case of expansion unaccompanied by the doing of work?

The disciples of Clausius, whose doings must have sorely troubled the spirit of Carnot, should not imitate the showman's ostrich of the desert, which, according to the showman, buries its head in the sand, and because it can see nobody, thinks nobody can see it. The only thing lacking, needed to set the steam question at rest, seems to be the wish to get at the truth and set it at rest. WILLIAM DONALDSON.

November 19th.

## TRACTION ENGINES

SIR,—We have heard much of the question of light railways running along the common high roads. Now, it must be evident to anyone that the cost of permanent way alone will spoil all chance of a decent dividend, and that after all the benefit derived will be extremely limited. What is wanted is a new code of laws, or the repeal of all existing laws, relating to traction engines, also one general and universal law instead of all the bye-laws, which are different in almost every district. Some local boards say an engine shall not pass our borders during the day, and another not far distant during the night. If the Board of Trade will take steps to sweep away all these prohibitory laws and give steam locomotion on common roads a chance, we shall certainly hear no more of the demand for light railways. Traction engines are now made heavy because the law says they must travel slowly, and consequently must carry heavy loads in order to make them pay. What is the man in front with a red flag supposed to be for? With regard to horses shying, I would suggest that the time has come when all horses should be broken in to traction engines, just as now to pass any ordinary object. Some horses object to pass a heap of stones, or a donkey, or a sweep, but they have to. Why should our locomotion on common roads cost five times as much as steam traction locomotion only because horses shy at these engines? Let a horse follow a traction engine for a day, and he will no longer be frightened. Anyone who has travelled in America will have observed that horses and engines are on the most friendly terms. Besides, what will become of shying horses when we have light railways on common roads? What railways did for the remote parts of England, traction engines can do for places distant from railway stations. If there were no restrictions against traction engines any farmer with 300 acres could use one to advantage. If we are to have progress in this direction, traction engines must be able to move from place to place on equal terms with horse carriages. A traction engine running in, say, three counties, has to pay £30 a year in order that it may pull a load. Now, traction engines do not do so much harm to the roads as the feet of heavy horses. As a matter of fact they do the work of a steam roller. As is proved where traction engines are most common, the roads are undoubtedly the best. See the roads in Kent. Engineers will not design a lighter or more pleasing-looking engine until there is a demand, and there can be no demand until the laws are altered. I hope every member of the Local Government Board will fully consider traction engines and the laws and bye-laws. This vital question should be fully ventilated. J. E. S.

November 20th.

---

SIR,—The letter of your correspondent "Traction" is a fair one, but sets up claims on behalf of traction engine owners far from fair. First, as to the licence: If the Government repaired all the roads they would be entitled to the fee, but they do not; when this is re-adjusted district councils will have something to say. The fees for licences in this county amount to about £60 per annum, the damage done by locomotives of all sorts about £1500. I agree with him that the working hours should be the same as other out-door trades. During the hunting season I am worried with complaints about road locomotives—hence my personal wish to stop them during the hunting season.

"An Agricultural Engine Owner" is of the usual type, and it is these that have done as much as anything else to cause such opposition to traction engines—men who cannot give one a civil answer, who renew their licence six months after date, who evade the law by only having the maker's name on the engine and trucks. When their dirty, snorting old engine stops they have to tear the road to pieces to start the load, and steal stones to put under the wheels; who stop on bridges and knock holes in the parapet because their suction pipe is too short, and no more can be got on the purchase hire system. I never conveyed the idea that the little harmless engine used for threshing machines should be licenced, as they bear the same proportion as a perambulator to a brougham; but other vehicles are taxed if not licensed, and I fail to see any comparison between these and a railway. The one purchases the land and makes its own highway, the other uses the public highway.

Why should agriculturists be exempt from paying for a licence? The farmer takes his barley to the malthouse with his two locomotives: he pays no licence; the malster must pay a licence for his one engine to haul it out. My statement as to stinking oil is the result of ten years' observations. Your correspondent is welcome to hold a different opinion: observant readers may judge for themselves. The judgment in the case of The Queen *v.* Savin enables any highway authority to ruin any traction engine owner damaging a weak road. Surely it would be better for the highway authority to prevent the damage. Any alteration in the statutes on the present temper of the public would be against traction engine owners.

That the laws require alteration is admitted. We have not heard what the owners require. What the highway authorities require is roughly as follows:—A joint licence for county and district council, the fees to be shared; a time licence for itinerant engines holding a licence in another county; annual inspection of every engine by a competent official, the engine to be indicated and the load to be drawn endorsed on the licence, no licence to be given to a bad engine. The driver to be examined by the same official, and only those holding his certificate to be employed. Any road authority to have power to prohibit the use of traction engines on weak roads. Traction owners to be placed in exactly the same position as other owners of vehicles for damage done to roads and bridges. ROBERT PHILLIPS.

November 21st.

---

SIR,—I am very glad to see the discussion in your columns on traction engines, and hope it will be the means of inducing more engine owners and users to take combined and well-directed action to effect what all desire. An association such as "I. H. M." writes about was initiated last year at the Smithfield Club Show. The makers give hearty support to it, so do a good many owners, including many of the largest, most experienced, and best known men in the country. But the numbers are not what they ought to be, if engine-owners really feel the present regulatous to be oppressive.

The subscription is low as the strength of such an association should be in its numbers. The committee will only spend money in law expenses when any important question of principle can be decided. It cannot help members to pay the fines they incur or the damages awarded against them for repairs of roads, &c., but every case brought before them receives careful consideration from the men who have been in every traction engine case for years past and useful practical advice given.

You, Sir, know well enough how impracticable any attempt at private legislation would have been last session. It is for engine owners to form public opinion in their own districts among their customers, employés and others, so that their members of Parliament or their candidates for the next Parliament will support this association in the Bill which it intends to bring forward at the proper moment. To carry on a parliamentary "agitation" costs money, and it is useless throwing away the slender resources hitherto provided by engine owners in efforts which must be fruitless.

The Smithfield Club have granted us the use of a room at the Agricultural Hall on Wednesday, December 14th, at 4 p.m., for our annual meeting, and I hope every engine owner who has a grievance will come to that meeting.

H. R SUMMERS, Secretary.
The National Traction Engine Owners' and Users' Association,
135, Upper Thames-street, E.C.,
November 21st.

## LOCOMOTIVES AND TRAINS.

SIR,—I have read your leading article, and also the correspondence on this subject, with some interest. I believe on the Great Northern Railway it is the custom never to take a pilot; and I am quite sure that, if such were not the case, drivers who at present will take fifteen or more coaches up to Potters Bar with every confidence and success would, if the pilot could be had for the asking, take him on occasions to help to do what they can at present do so well alone; and is not the foregoing a probable explanation of much of the piloting at present done on other lines?

Mr. Macdonald talks of the inability of the old North-Eastern engines to cope with the present-day coaches and the greater booked speed now required. With regard to the coaches, except for a few eight-wheel sleepers which count as one and a-half, and which Mr. Macdonald says are easier to haul, the Great Northern six-wheeler has for years been the standard East Coast coach. As to greater booked speed, the 1.42 a.m. ex Newcastle is given 108 minutes from Newcastle to York, with the stop at Darlington. In 1881 it took only five minutes longer; and long before that date the up Flying Scotchman had for some years been leaving Newcastle at 12.50 p.m. and reaching York at 2.35, with a stop at Darlington. I have therefore not the least doubt that No. 905, the old engine built by Mr. Fletcher—which was piloting the train which came to grief at Northallerton—could have worked the train unaided with the greatest ease. On June 16th, 1893, No. 904, a sister engine, took the day Scotch with thirteen on from York to Newcastle in 1 hour 38 minutes, with a bad start for a few miles out of York owing to adverse signals.

Mr. Rous Marten gives a run with another engine of the same class from Newcastle to York in ninety-two minutes with nearly 180 tons, stopping at Darlington and gaining ten minutes; the 44¼ miles from Darlington to York being run in forty-eight minutes. Mr. Pattinson gives a run from Newcastle to York by No. 269 with 15½ coaches in just under 100 minutes. From such examples as the above I form my conclusion. You recently illustrated two fine Great Western engines, which you described as the standard express engines. You remarked on the performances of twenty engines similar to the Agamemnon class—by which, I suppose, are meant engines of the 3001-3030 class, which differ from the class under discussion in having no leading bogie, and also cylinders 20in. by 24in. instead of 19in. by 24in. Eight of this class were built as broad gauge convertible engines, and were, on the abolition of that gauge, converted to narrow; and you illustrated one of the engines, both as converted and unconverted. This class is now being assimilated to the Agamemnon class by having the cylinders reduced and a bogie added. Again, are several engines of the Armstrong class new—*e g.*, Nos. 7 and 8 and 14 and 16? Were not Nos. 7 and 8 built as a narrow gauge and broad gauge compound respectively, the latter being convertible? And were not Nos. 14 and 16 built as broad gauge convertible engines, with only a leading pair of wheels, and not as now on a leading bogie

November 14th. E. B. D.

SIR,—In view of the comparisons between English and American express railway speeds which have from time to time appeared in your columns, I trust that a brief account of my experiences on a fast American train last month, during a visit to the United States, may be of interest to your readers. The journey in question was from Buffalo to New York by the Empire State express, on the New York Central and Hudson River Railroad. As the traveller "boards" the train at Buffalo he is confronted by a large placard announcing that this is the "fastest train in the world." That such a bold claim should have been allowed to go uncontested seems at first sight remarkable, if we assume that England can boast the fastest speeds, if not the most luxurious travelling. I hope to show, however, that the claim is not entirely unfounded, however unpalatable it may be.

I append below a tabular statement showing the mean speeds between stations and over the whole run of the train in question. For comparison with the best English practice, I show the corresponding details of the Scotch express between London and Edinburgh—a distance nearly equal to that covered by the American train—extracted from the time-tables of the current month :—

*Empire State Express, October 2nd*, 1894.

| Miles. | Stations. | | Time. | Mean Speed between Stations. Miles per Hour. |
|---|---|---|---|---|
| 0 | Buffalo | dep. | 1 0 p m. | 50 5 |
| 69 | Rochester | arr. | 2.22 p.m. | |
| | | dep. | 2 25 p.m. | 53 3 |
| 149 | Syracuse | arr. | 3 55 p m | |
| | | dep. | 4 0 p m. | 53·0 |
| 202 | Utica | arr. | 5.0 p m. | |
| | | dep. | 5 5 p m. | 51 8 |
| 297 | Albany | arr. | 6.55 p m. | |
| | | dep. | 7 0 p.m. | 44 |
| 440 | New York | arr. | 10.15 p m. | |

Mean speed, including stops, 47 6 miles per hour.

*Scotch Express, November*, 1894.

| Miles. | Stations. | | Time. | Mean Speed between Stations. Miles per Hour. |
|---|---|---|---|---|
| 0 | King's Cross | dep. | 10 0 a m. | 51·8 |
| 105½ | Grantham | arr. | 12·2 p m | |
| | | dep. | 12.7 p.m. | 50·5 |
| 1·8 | York | arr. | 1 45 p m. | |
| | | dep. | 2 5 p.m. | 49·5 |
| 268½ | Newcastle | arr. | 3 42 p.m. | |
| | | dep. | 3 47 p.m | 49·6 |
| 335½ | Berwick | arr. | 5.8 p.m. | |
| | | dep. | 5.13 p m. | 44 8 |
| 393 | Edinburgh | arr. | 6 30 p m. | |

Mean speed, including stops, 46·3 miles per hour.

From these tables it will be seen that the highest mean speed between stations of the Empire State express is 53·3 miles per hour, against 51 8 of the Scotch express; while the average over the whole distance, including stops, is 47·6 miles per hour for the American train, against 46 3 for the English train. In the latter case twenty minutes is allowed at York for lunch. If this prolonged stop were reduced to, say, five minutes, the mean speed would be raised to 47·6. In the United States, where trains carry so much of what we should consider station accommodation with them, this stop for meals is unnecessary, and, in my opinion, the train under consideration deserves full credit for the increased speed thereby rendered possible.

In the length of run without stop also the American train takes the lead—viz , 143 miles from Albany to New York, against 105½ from King's Cross to Grantham. So far as I am aware, this run of 143 miles is nowhere equalled at the present time. Being anxious to ascertain the highest speed attained over short distances, I timed mile after mile, and observed a speed of over 60 miles per hour for considerable periods. The fastest speed I recorded was 70½ miles per hour. This, I believe, does not equal speeds on the Great Northern Railway, which habitually reach 72, and occasionally 74 miles per hour, between Grantham and King's Cross. At Syracuse and New York the Empire State express arrived two minutes before "schedule" time, and at the remaining stations absolutely punctual. In all cases the start was "on time." The train consisted of a locomotive weighing, with the tender, about 90 tons, and a train of four cars weighing about 120 tons. The line has four tracks the whole distance, with numerous water troughs to save the weight of a large water supply on the tender.

It must be borne in mind that the two trains under comparison are in regular daily operation. If exceptional trains, such as the "Exposition Flyer," which was run during the World's Fair, and accomplished the journey from New York to Chicago in nineteen instead of the usual twenty-four hours, were compared with the Scotch express during the famous race to Edinburgh in 1887, when the time was reduced from 8½ to 7½ hours, different results might be obtained. My object is rather to show that the best regular express service in the United States is, apart from the superior comfort, at least as fast as that of our own country, which probably means of the world. I may be wrong in choosing the Scotch express as representing this side. If so I shall be glad to learn my error. I send herewith a photograph of the locomotive which hauled the Empire State express for a portion of the journey. The cylinders are 19in. by 24in., and the two pair of drivers 6ft. 4in. in diameter.* ARCHIBALD P. HEAD.

47, Victoria-street, S.W.

[We published a large engraving of Mr. Buchanan's engine in our impression for June 17th, 1892.—ED. E.]

SIR,—The engines so tenderly inquired after by "Scrutator" were built by Hawthorn, I believe, in 1882, and are still running; they had 6ft. 8in. coupled wheels, 3ft. 3in. truck wheels, and about 1100 square feet of heating surface, and weighed 38 tons. Such relics of the economical epoch of railway management as tenders with the pick-up are only to be found on the London and North-Western and Lancashire and Yorkshire Railways. A section is given on the sheets of drawings brought out by Mr. Theodore Smith, of Darlington, a few years back. Mr. Norman Macdonald's remarks as to weight of coaches and speed of train are quite beside the question, as the weight of the whole train has already been given by one of your correspondents as 194 tons, and the speed is not so high as that of many other trains. Besides, the North-Eastern steed does not usually make up any time on this stage of the road, knowing that the Great Northern Black Bess is willing to shoot sky-rockets from its funnel all the way to London—and finally expire with a burnt-out fire-box if necessary—to make up time lost by other companies, and to keep up a costly reputation for punctual arrivals at King's Cross.

In conclusion, I wish to apologise for taking up your valuable space for this the last time; and I should like to ask those railway men who resent outsiders writing to your columns on railway matters, to show us any railway in England except the London and Brighton which has lowered its working expenses by the use of modern locomotives. Everyone knows that heavy engines would show splendid results if employed to haul a large number of passengers; but they can only increase expenses per train mile as long as traffic managers continue to run such a number of light trains in response to some imaginary demand for more trains. To say that Manchester demands more than forty fast trains to London every day, or that such towns as Nottingham, Sheffield, Leicester, or Birmingham, are crying out for an extra service of trains, in addition to numerous express trains already run by the Great Northern, Midland, London and North-Western, and Great Western Railways, only shows what ridiculous excuses railway directors will give for embarking on a policy which has already nearly ruined one of our great railways. F. BOWLES.

November 19th.

### GOVERNING ELECTRIC LIGHT ENGINES.

SIR,—It is difficult to keep one's temper in the face of such a string of ill-judged criticisms. assumptions, and conclusions, as Mr. James Dunlop again puts forth in your issue of the 9th inst.; and all this for the sole purpose of drawing your readers' attention to the stirring fact, that he has "invented a system or trip-gear diagram." I should feel intensely grateful for his gratuitous assistance to improve my knowledge of the gear I have introduced, but for several good reasons: (1) Ever since I had anything to do with the Proell apparatus I have been taught all about its action by a diagram constructed by Dr. Proell himself—he would not have been conceited enough to call it an invention. I hand you herewith a Proell prospectus, issued 1886, containing this diagram, which is the oldest printed illustration on which I can lay my hands. (2) Mr. Dunlop's own diagram is perfectly unintelligible from his own description, except possibly to those who already understand such diagrams, and therefore stand in no need of his "invention." (3) Mr. Dunlop bases his diagram on an entirely wrong angle of advance, viz., 38 deg. negative, while for the obsolete Proell apparatus a positive angle of 80 deg. was used.

Fig. 1

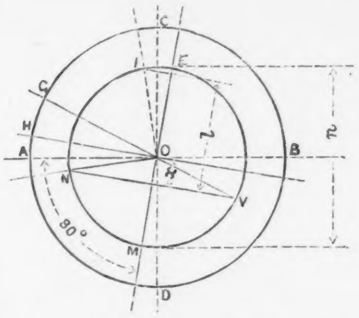


Fig. 2

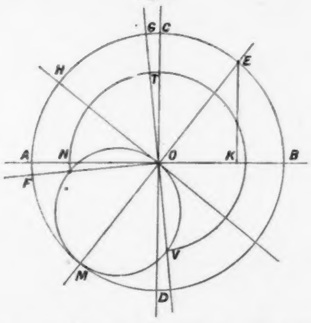

Fig. 3

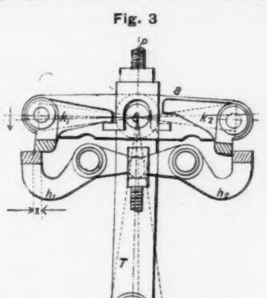
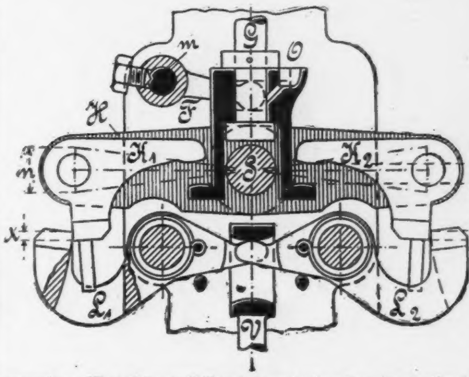


I beg to hand you herewith the correct Proell diagram—Fig. 1—which I will not go to the length of explaining for those of your readers who are not familiar with such graphic demonstations; others will not require it. I have used the same letters as Mr. Dunlop, and it will be seen how the mere insertion of the correct advance angle influences the diagram, and reduces the wicked arc H G from the length, as Mr. Dunlop draws it in Fig. 2, to the correct one in my own Fig. 1. This shows the theoretical possibility of the inactive parts engaging between about 1 per cent. to 7 per cent. of the stroke, but not, as Mr. Dunlop maintained, between 16 per cent. and 43 per cent. In Mr. Dunlop's illustration, Fig. 3, particular stress is laid on the dimension $x$, the "overlap," as we call it. Every reader will, of course, expect that this dimension is an important function in Mr. Dunlop's diagram, while, as a matter of fact, his $x$ has nothing to do with it, but it is the dimension $x$ in my illustration Fig. 4, the "hang through" which is at the bottom of all the alleged misbief. It is certainly not to be wondered at that none of the engineers to whom I have submitted Mr. Dunlop's invention could reconcile it even with his own description, the mistakes of which can only be found out by somebody who is a good deal more conversant with the subject than the inventor of the Dunlop diagram. If Mr. Dunlop expected anybody to appreciate his addition to modern science, he should at least have been careful enough to avoid such mistakes as that he once calls O E the position at which the descending bell-crank comes in contact with its lifter, while later on he represents the same position O E as the extreme position, and besides he might at least have told your readers what all his circles and intersections mean.

As it stands, Mr. Dunlop's diagram will be of no use to anyone. But even supposing that Mr. Dunlop had re-invented the proper form of the diagram, and that he had been able to explain it intelligently to the uninitiated, and that you had given him sufficient space for the purpose, what would have been the result of all this waste of energy? That a theoretical diagram shows on paper the possibility of a certain action—but in a much reduced degree than Mr. Dunlop made out—in an obsolete form of the Proell apparatus. That this possibility does not take place in practice is absolutely proved by the indicator diagrams I handed you with my last letter, and which I shall thank you to print with this one. The reason is simply this, that in addition to the kinematic motion—which is alone shown in such valve diagrams—there are in the Proell apparatus, which has a free falling valve, dynamic influences, as the time the valve requires to fall, the action of the air buffer, &c., which upset all such paper conclusions. Having learned this simple fact, I trust Mr. Dunlop will set to work and invent another diagram which takes these important factors into account, unless he prefers to accept the indicator diagrams as conclusive.

Fig. 4



Mr. Dunlop's insinuations that we had allowed a fault to remain, because we either did not know of its existence or else did not know how to overcome it, is perfectly uncalled for. No user even of the obsolete construction has ever complained to me about the fault—which Mr. Dunlop has invented—because in practice it did not exist, and the construction would certainly not have been altered in this detail if the improved Proell gear had not made such a course desirable. HERMANN KUHNE.

25-35, New Broad-street, E.C., November 19th.

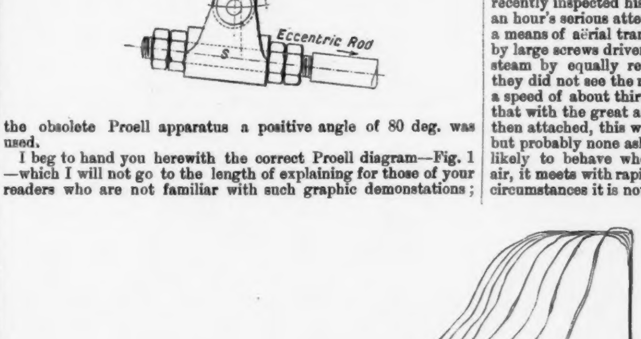
### PIVOTED ARCHED BRIDGES—HARLEM BRIDGE.

SIR,—In your article on "Pivoted Arched Bridges" in THE ENGINEER of October 26th, page 355, there is an obvious error in the reference to the Harlem Bridge, New York, which bridge has not "solid cast steel" arched ribs. There are several bridges over the Harlem river, the one referred to being the Washington Bridge at 184th Street. This has two arched spans of 510ft., each composed of six plate girder arched ribs, the depth of the girders being 13ft., which is a good size for the web plates, which are ⅜in. thick, except at the skewbacks, which are ⅝in. thick. At the skewbacks each girder bears against a steel hinge pin, 18in. diameter and 3ft. long. Your article referred to bridges mainly, but it may not be amiss to state that several of the buildings at the Chicago Exposition had pivoted and three hinged arched roof trusses—including one of 368ft. span—while a similar style of construction has been adopted for the roofs of some large new armouries—or drill-halls—and railway stations.

New York. E. E. RUSSELL TRATMAN, C.E.

### THE FLYING MACHINE.

SIR,—At the invitation of Mr. Maxim a larger number of people recently inspected his flying machine than had probably ever given an hour's serious attention to his development of the aëroplane as a means of aërial transit. They saw the great machine propelled by large screws driven by remarkable steam engines supplied with steam by equally remarkable and ingenious boilers. Although they did not see the machine lifted upon and by the air—although a speed of about thirty miles an hour was reached—many realised that with the great aëroplane, aided by those of smaller size not then attached, this would be possible. Comments were numerous, but probably none asked the question how is such an apparatus likely to behave when, propelled at a high speed through the air, it meets with rapid air currents from either side? Under these circumstances it is not quite obvious that the aëroplanes would not "scoot" like a kite and take advantage of tilting side winds to dive and make other erratic movements, in spite of the weight of the car and its machinery.



DIAGRAMS FROM ENGINE WITH PROELL VALVE GEAR

Some experiments made with small aëroplanes launched from an altitude rather indicate that this would happen. The tendency of the weight suspended from the aëroplane is, of course, to right the machine, but driven through the air at thirty miles an hour there seems little to prevent the aëroplane from acting indifferently in a vertical or more or less horizontal plane, once from any extraneous cause it got an inclination; and the question arises, would not this happen much more quickly than gravity could act as a righting force? Let the aëroplanes once receive a considerable tilt and take to erratic plunging and diving, there seems to be the possibility that the whole machine could turn over. Instantaneous reduction of the horizontal speed of propulsion would no doubt enable the righting tendency of the car weight to come into play after the manner of a parachute. It is difficult, however, to imagine this reduction of speed of horizontal translation taking place as quickly as a sudden dive due to the action of a side gust. No doubt Mr. Maxim has considered these questions, which seem to point to the use of propellers on vertical spindles as the means of maintaining the required altitude independently of the horizontal propulsion.

London, November 20th. B.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

H. B.—*Gustave de Laval, Stockholm. The Parsons Turbine Company, Newcastle-on-Tyne.*

H. J. D. (Hammersmith).—*We have not yet published any further particulars of the engine to which you refer.*

E. J. B.—*There are no recent books on the English locomotive which are comprehensive. You will perhaps find Mr. Hughes' book just published by Messrs. Spon answer your purpose.*

W. J. W.—*Your letter has been received, statements and diagrams correct, but the problem only referred to the effect of an extraneous force. That of a contained force is obvious, and is proved constantly by every locomotive or bicycle running on the roads.*

T. P. (Retford).—*We regret that we are quite unable to assist you to obtain the address you want. We can only suggest that you should advertise in some South American paper, or apply to the head offices of the railway companies in London.*

J. (Govan).—*It can do no possible good to publish generalities. The facts are apparently or really against you. You will find it very difficult to persuade anyone behind the scenes that our great ocean companies persist in building a class of ships that will not pay, or that Board of Trade restrictions prevent English, Scotch, and Irish shipbuilders from turning out from their yards the finest ships in the world.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 8d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, November 27th, at 8 p.m. Paper: "The Machinery of Warships," by Mr. Albert J. Durston, Engineer-in-Chief of the Navy. Friday, November 30th, at 8 p.m. Students' meeting. Paper: "Sub-aqueous Excavation at Newry," by Mr. Charles H. Olley, Stud. Inst C.E. Mr. J. Wolfe Barry, C.B., member of Council, will take the chair.

Society of Arts.—Wednesday, November 28th, at 8 p.m. Paper: "Experiments in Aeronautics," by Hiram Maxim. Sir Richard Webster, G.C.M.G., Q.C., M.P., will preside.

---

# THE ENGINEER.

*NOVEMBER* 23, 1894.

### THE UTILISATION OF THE NILE.

We were not far wrong in our forecast regarding the Assouan Dam, for in the *Times* of Monday its Cairo Correspondent tells us that Mr. Garstin, the Under Secretary to the Ministry of Public Works in Egypt, presented a note on the 8th instant, proposing modifications in the Assouan work, and stating that the scheme will most likely now consist of the construction of a dam having its crest at a reduced level of 106 metres. Thus the dam will be 26ft. lower than that—at a R. L. of 114 metres—originally approved of by the Government, and will retain water sufficient for either Middle or Lower Egypt, but not for both. It is further stated that this concession has been made by the Egyptian Government in deference to the strongly expressed protests of many of the European archæological societies, and that the Ministry "has endeavoured to reconcile the material interests of the country with those of science." It is clear that this is a retrocession on the part of the Government, and that it will delay the reclamation of the uncultivated and salted lands, as well as many other improved conditions of the country hoped for from the original proposals; but it will spare from submersion all but a portion of the island of Philæ and its celebrated temples. The smaller monuments, which are below the full supply level, are capable of being protected by special works to be planned in accordance with the wishes of the learned societies. The same correspondent announces the discovery of another favourable site for a reservoir, about 150 miles South of Wadi Halfa, but this being outside the limits of Egyptain protection, political considerations preclude the immediate examination and, possibly, the future construction of the work. The urgent necessity of early action in the duty of constructing a reservoir was made very apparent in the season that has just past by the difficulty which the Irrigation Department experienced in supplying the cultivators with a sufficiency of water. The Nile flood also, although not a maximum one, gave occasion for much anxiety by the persistent maintenance of an abnormally high level during the critical month of October. The former of these facts accentuates the necessity of an increased storage, and the latter the desirability of a relieving or controlling reservoir, such as might be looked for in the direction of a project such as that of the Wadi Rayan.

As, owing to a misprint in our earliest notice on this subject, some difficulty may occur to our readers in following our figures, we here quote the paragraph of Mr. Garstin's note from which we obtained our data. He writes:—"For the whole of Egypt we therefore need a reservoir with a storage capacity of—Upper Egypt, 1,160,000,000 cubic metres; Middle Egypt, 950,000,000 cubic metres; Lower Egypt, 1,551,000,000 cubic metres; total, 3,661,000,000 cubic metres." This separation of Upper Egypt into two divisions of Upper and Middle is quite arbitrary, and has been adopted by Mr. Garstin for facilities of reference, as he writes: "I divide Egypt into three parts—Upper Egypt, or the country south of Assyut; Middle Egypt, or the country between Assyut and Cairo; Lower Egypt, or the country north of Cairo." As matters now stand with the Assouan reservoir full supply at R.L. 106 00 only a metre higher than our assumption of last week—the Egyptian Government will be able to supply only 1065 millions of cubic metres to meet the above total, and the question at once arises. How will this supply be distributed, and what further steps can be taken towards the solution of the economic problem, and to advance the prosperity of the country? It will probably be found expedient to devote this reduced supply to the irrigation of Upper Egypt, for, besides being insufficient for all the wants of Lower Egypt, there would be much waste on its way to the greater distance. Its diversion, moreover, from the upper country might cause a not unreasonable jealousy among a population whose interests had suffered from the storage of the water, were it allowed to pass on to lands beyond their immediate ken without benefit to them or their neighbours. It may also be assumed that the use of the water will be confined to those parts called Middle Egypt, because there the preparations for irrigation are in a more advanced state, its most difficult and costly canals having been already constructed, while the more southern parts need both weirs and canals, and, as Mr. Willcocks puts it, "should naturally be dealt with after the others." If this view be taken by the Government of Egypt, attention is at once called to the Waddy Rayan scheme, which, although perhaps not to be supported in the face of a completely satisfactory project like the original Assouan reservoir, yet providing as it does a storage of 1000 millions of cubic metres, in the circumstances as they have developed themselves would with the surplus of the Assouan supply, go far towards serving the needs of Lower Egypt, thereby freeing the reduced storage at Assouan for the benefit of Middle or Upper Egypt. It would also in same degree help to reduce the anxieties and dangers of an abnormally high Nile. It cannot be concealed that the cost to the country of this dual project will be far in excess of that of the original plans, if carried out; but the blame of this must rest with those who have forced, as it were, the Philæ compromise from the Government of Egypt.

That the scheme is not considered as devoid of merit by the Egyptian Public Works officers is proved by the following extract from Mr. Garstin's note:—"I conclude by saying that the Wadi Rayan reservoir project is a feasible one, although, even under the most favourable conditions, the element of doubt to which I have already called attention must always exist. As compared with some of the Nubian reservoirs, it is a very costly work. It could at first be filled by a canal from the Nile, and afterwards maintained at a working level by means of the Bahr Yusuf through the agency of a barrage at Assyut. At a cost of not less than £E.2,727,420, it would be capable of assuring the water supply of Lower Egypt. It would take not less than ten years from the date of commencing work before use could be made of it; but, at the same time, there would never be any question of danger to the country connected with it. Were it not for the doubts expressed above, its excessive cost, and the fact that it would only serve Lower Egypt, I should not have hesitated to recommend its execution to Government. As matters stand, however, certain of the Nubian reservoirs are considerably less costly, and capable of relieving a far larger area of country. I am compelled, then, to abandon the Wadi Rayan project in their favour." This, be it remembered, was written while the construction of the Assouan dam, as originally proposed, was a more than possible contingency. How much more value must the project now possess since its advantages have been enhanced by the restriction of the Assouan project.

### TRACTION ENGINES.

The article on Steam on Common Roads which appeared in our issue of Nov. 2nd has elicited a considerable number of highly unsatisfactory letters from owners and users of traction engines. The writers make vague complaints; they denounce the existing system of legislation; they demand parliamentary interference, and in no one case do they even attempt to define what changes in the Highway Acts they deem desirable. They manifest the most delightful oblivion concerning the generally accepted fact that the highways of a country have not been specially constructed or reserved for steam locomotives. They make demands which are utterly exorbitant and absurd. Thus one of our correspondents insists that every highway bridge shall be so constructed that it may be habitually crossed and recrossed by loads of 30 tons. Another will have it that road locomotives weighing 15 tons are to be allowed to run where they like; and these are not the least of the suggestions and demands which have reached us. No possible good could arise from the publication of literature of this sort, and it has gone into our waste basket. But a good cause should not be made to suffer because of the wrong views of those who advocate it, and we have no doubt that sensible men exist who are competent to deal with the very complex questions at issue, and formulate something that might be utilised as a guide in framing new regulations for the use of steam on highways.

It is very easy to suggest a dozen questions which should be attacked and settled by builders and users of road locomotives. One of the very first that presents itself is the external appearance of the engine. It has been said, and said with truth, that horses are not afraid of steam rollers, because the latter are not ugly, noisy, or evil smelling. Not long since, at 9 a.m., might be seen in a London suburb a steam roller at work. It was in perfect order, very clean, the engine works boxed up, absolutely no smoke, no steam, no fire visible, no noise save that made by the roller in dealing with the whinstone road metal. There was nothing here to offend horses, and accordingly the considerable traffic of the road was carried on without trouble. About half a mile further on we found a traction engine of large size. By the maker's name-plate, deciphered with difficulty under a coat of grime, we learned that the engine was seventeen years old. All the gearing was exposed; part of the ash-pan was gone, and fire dropped on the road. There was a considerable leak between the saddle of the cylinder and the boiler, from which steam escaped in offending volumes. The safety-valve was leaking. The wheel rims were worn and patched. The dirt of the whole was indescribable. Behind the engine were two heavy covered vans. What they contained we are unable to say. The decrepit old engine was sorely beset to haul these wagons up a moderate hill. The noise of the exhaust resembled small-arm practice, and fire was flung freely from the chimney, in the side of which there was more than one hole. Everything down to the firing-tools appeared to be adrift more or less, and the clanking and banging were indescribable. The wheels slipped every now and then, to the great detriment of the road. It was not to be expected that horses could pass this engine and its load; nothing more abominable could be put on a highway in a civilised town. It was only necessary to compare the proceedings of the traction engine and the action of the road roller to understand why different views may be taken concerning the expediency of permitting steam to be used on our highways. It may be said that the case we have stated is exceptional; it is nothing of the kind. A tolerably extensive acquaintance with traction engine work suffices to convince us that it is not. Mr. Phillips, whose letter will be found in another place, does not exaggerate in the least concerning the abuse of steam on common roads. But let us ask ourselves why it is that engines so unutterably offensive should be used? Our answer is, that the law is mainly responsible. If, for example, nothing had been said about a red flag, and the traction engine owner had been made responsible for damage caused by his engine, he would long since have taken great care that it should be as little offensive as possible. Thus the whole of the machinery might have been placed between side frames under the barrel of the boiler, as in a railway locomotive. There would be a silencer on the exhaust, or else the engine could have compound cylinders, which greatly soften the blast. It is unnecessary to go into detail; everyone who is versed in steam road locomotives will understand what we mean. But such an engine would be a little more expensive to build, and a little more costly to work than the ordinary engine. Why should the extra expense be incurred, when a dirty red flag carried by a dirty little boy a hundred yards ahead of the engine entirely exonerates the owner? It has been much cheaper and less troublesome to comply with the Act of Parliament, than it would have been to make engines which would give little or no offence. In this way the nominally stringent and oppressive regulations of which our correspondents complain have been in the long run blessings in disguise, and not a few traction-engine builders have grasped the full significance of this fact, and acted accordingly. Let but a few rules as to working powers, &c., be complied with, and the design and condition of the engine may be whatever the maker and user please. If there is to be a change in the Highway Acts, our readers may rest assured that it must be preceded by evidence that a radical change—a return to old-time practice in many respects—will be made in the design of traction engines. Here then is a question for free discussion—What is the least offensive form that a common road locomotive available for heavy haulage can take?

Another most important question is the construction of the wheels. We do not allude to the old and time-worn question of spring wheels, a puzzle solved every year—for that year—and turning up always with the freshness of youth. We ask what kind of wheel is least likely to damage roads? The best wheel for traction on the highway ever produced was Thomson's, with an india-rubber tire. It was only necessary to see an engine fitted with these tires at work to know that nothing more mechanically perfect could be devised. But then those tires were exceedingly expensive. The cost was prohibitive. Can no substitute be found? What about the pit rope tires used fifteen or more years ago by Mr. Leonard Todd between Leith and Edinburgh? How does wood answer? Why is it that ribbed tires are used, unless it be that they are on the whole the worst things available.

We mention only two out of at least a dozen subjects which clamour for discussion. The National Traction Engine Owners' and Users' Association propose to hold a meeting during the Smithfield Club Show to discuss various questions of interest. We dare venture to say that every speaker will contemplate the use of the traction engine as it is, and deal with it as though existing designs were final. There is reason to believe, however, that the hands of the traction engine users will be forced, and that they will be driven to adopt such changes in design and construction of their engines as will disarm opposition. There is nothing very dreadful in this, we may add, for the changes need not be of a very radical character, at least as regards the engines made by some firms. In another page we reproduce a circular just issued by the Association, and a notice issued by the Great Western Railway Company. We commend them to the consideration of our readers. They are eminently suggestive.

### NEW RAILWAY PROJECTS.

THE notices of intention to apply for additional powers or for new Bills are this year very limited so far, so that it would seem that there will be only a scanty crop of projects to undergo the revision of the parliamentary committees. The North-Eastern Railway has one proposal for additional powers, which includes the making of a short railway from its main line near Cramlington to Newsham to facilitate the shipment of coal; another short line near to Normanby, to open out the passenger traffic there, and several widenings of the line in various points. The Lancashire and Yorkshire Railway desire powers to make new railways in Manchester, and a series of comparatively small works in the West Riding of Yorkshire—at Halifax, Bradford, and other points. The London and North-Western Railway has in view an addition to its works in the West Riding—at Heckmondwike, Batley, and neighbouring parts. But the works that are contemplated are by no means large in the aggregate; so that the projects that affect the North are limited. There are signs that Scotland will furnish some important projects over which there will in all probability be a strong parliamentary fight; and there will also be some proposals in regard to the South-West—Cornwall, Devon, and South Wales—that may also be keenly contested. But so far the area of the parliamentary proposals is one that is limited, and it would seem that there is for some cause a check to the pugnacity of the promoters. It may be that that check arises from the feeling that at the present time legislation presses hardly upon railways, both in enforcing the employment of a larger staff, the payment of continually-increasing sums for rates and taxes, and in other ways the putting of additional burdens upon them. It is evident that the growth of population will enlarge the traffic on the railways, both passenger and goods, and if the projects of new lines and works be kept limited, there will be of necessity a fuller bulk of traffic on the lines and a better return. It is the decision of capital, and it is one that is forced upon it, though it is one that must be regretted. It would have been interesting to trace the effect of the creation of new works on the yield of capital, but this is not now needed. The projects certainly seem to point to a diminished rate of expenditure of capital for many lines in the early future.

### TRADES UNION WAGES AND OLD AGE.

IN his monthly report to the United Society of Boilermakers and Iron Shipbuilders, the secretary, Mr. R. Knight, comments on the changed relationship of employer and employed. "We live," he says, "in a time of trade competition so severe that many of the best features in the old relationship of master and servant have been crushed out of sight, and old age and loss of service now count for nothing in the race for profit. In nine cases out of ten the approach of old age is the signal for dismissal, and grey hair or spectacles are often fatal objections. Thus the number of our superannuated is increased, and the number of paying members reduced." This is most unfortunate for the Society's funds, no doubt, but it is only what Mr. Knight and the members generally should expect; only, indeed, what a superannuated fund is meant to provide for. The slur, therefore, upon employers, which is implied in the secretary's remarks about "old age and long service" counting for nothing, may well be repudiated and resented by every employer in the kingdom. Allowing that grey hairs and spectacles are so positively the "signal for dismissal," as is here maintained, the blame—if blame there be—assuredly rests with the trades unions themselves, and the hard-and-fast lines which they lay down and enforce for the payment of their members. Employers maintain that it is impossible in these days of keen competition to pay the full rate of wages to old men who are unable to do the same day's work that they did when younger. Many employers, we know, would gladly keep on their old hands at slightly reduced rates of wages, and many men would gladly accept such terms, but the Union's officials or members step in and say "No! You must pay the full rates to all the men employed." No doubt the younger members do not regard with regret the discharge of older men, since that discharge gives employment to younger hands. Examples of how the inflexible wages rate operates are within the experience of almost every firm of employers. To instance one case will be enough. The employers in a large engineering works on the Clyde being desirous of retaining several old hands whose physical infirmities rendered them incapable of earning the full trades union rate of wages, kept them on at a reduced wage. The consequence was that the other men hearing of this, promptly threatened to put the works "on strike," unless the union rate were restored to the old men. As the amount involved was trifling, and the annoyance threatened serious, the employers gave in. Humanely enough, they did not retort by throwing their aged operatives out of work, and a burden, in consequence, upon the funds of the Union. All employers, however, have not got it in their power to act thus generously, and it is little to be wondered at, or even deplored, that the funds of the Society are more and more being drawn upon. If the younger and abler workmen, who are of course always the more numerous section, insist upon the maintenance, under all circumstances, of a hard-and-fast and irreducible rate of wages, they must make up their minds to bear, without grumbling, the cost of maintaining the aged and absolutely superannuated of their number. They must recognise, too, that when their own day of old age and physical decay comes, the prospect is that they will be denied work, which under a less inflexible system of wages might have been given them, and they must become a burden on the funds of the Union. It will thus be seen, and the sooner Mr. Knight and those for whom he acts as "guide, counsellor, and friend" recognise it the better, that the responsibility for crushing out of sight "the best features in the old relationship of master and servant" rests very largely with workmen themselves, and the rigid and inequitable rules by which they coerce employers.

### THE FUTURE OF COAL WORKING.

A FEATURE of the coal trade, which does not obtain the attention it deserves, is the rapid development of the coal country, concurrent with the diminished demand for the output. There has rarely been a time when so many coal enterprises have been in course of energetic initiation. Take Yorkshire as an example. There is within the memory of middle-aged men a most extensive tract of country, which was at one time entirely given over to pastoral pursuits, and which is now dotted here and there with colliery shafts, flying all day long what the Duke of Portland called "the black flags." A few farm hands may be seen labouring on the surface of the land, but they are as nothing to the thousands of men burrowing underneath for "the black diamond." To-day the colliery extensions are more important than ever. The trend of the new coal projects is towards the East. Immense fields have been opened in the wide district ranging from Mexbro' and Swinton towards Doncaster. The pleasant slopes opposite Conisbro' Castle, once sacred to lovers of "Ivanhoe," are no longer the favourite hunting grounds of students, who went there to muse in solitude over the days of Athelstane the Unready, and to revive in their imagination the struggles of the dead past. The Cadeby collieries, amongst the most extensive in England, now stand on the banks of the Don, opposite the grey old Keep, and, underneath, the ground is being worked for its precious deposit, which has been found in payable seams for many miles. All the district between there and Doncaster is believed to be a coalfield, and there is no telling how far further the mineral beds may extend. A similar remark applies to Derbyshire, Nottinghamshire, and other counties where boring operations have confirmed the expectations of mining engineers. All this enterprise suggests the question—Where are customers to be found for the vast quantities of coal which must, in a very short time, be brought daily to the surface? Although English fuel is preferred upon the Continent, there is a limit to the requirements of that market, and the tendency of scientific experiment, as well as the exigency of business experience, points to there being less use made of the raw material for heating purposes in the future than in the past. The position is simply this—that while the demand for coal as it comes from the pit is not sensibly increasing, the supply of the valuable material is advancing at an enormous rate. England is not again likely to resume her place as the workshop of the world, and other countries are more bent than ever upon developing their own resources. Each nation naturally aims at being "self-contained"—that is, being able to make for its people all her people need. Several of them, indeed, are not only able to supply their own inhabitants, but to compete with England in the open markets of the world, as well as at her own doors. Thus it is that British trade is attenuating, and we are face to face with the grave problem of British work decreasing while British workers increase. This is now being complicated by that other problem, which must soon demand solution—what to do with the surplus coal of which modern enterprise is robbing Mother Earth. Our export trade, important as it is, suggests a further question, and that is the wisdom or unwisdom of scooping out our national coal cellars for the advantage of our continental competitors. However that may be, the outlook at the present seems to point to the coming of a time when there will be more coal than customers, and that period is not only fraught with difficulty for colliery owners, but for all who make a livelihood by and through working in the mine.

## LITERATURE.

*The First Principles of Building.* Being a Practical Handbook for Technical Students. By ALEX BLACK, C.E., architect. London: Biggs and Co. 1894.

*Specifications for the Use of Surveyors, Architects, Engineers, and Builders.* By J. LEANING, F.S.I. London: Sampson Low, Marston, and Co. 1894.

*The Sanitary Arrangement of Dwelling Houses.* A Handbook for Householders and Owners of Houses. By A. J. WALIS-TAYLER, C.E. London: Crosby Lockwood and Co. 1894.

MR. BLACK's book is a small octavo volume of 329 pages. It is fairly well illustrated. It may be regarded as a species of enlarged dictionary of elementary architecture, the author describing briefly most of the materials and processes used in building. A great deal of information is thus supplied; but Mr. Black has not attempted to do too much, or to handle any one of his multifarious subjects exhaustively. The title describes the book very fairly. There is a good index.

Mr. Leaning tells us in his preface that these "Notes" were originally published in the *Building News* in 1893. They have been augmented and improved in the present little volume of 140 pages. The book contains instructions for drawing specifications, and each set of instructions is supplemented by specimen clauses. No doubt even the practical architect will find in its pages useful hints and suggestions which will refresh his memory.

We are not at all sure that the average householder can gain much useful information from a book such as Mr. Walis-Tayler's. It is neither better nor worse than a host of treatises on sanitary matters. It contains a great number of engravings, principally referring to the products of one sanitary engineering establishment. It is more calculated, perhaps, to satisfy curiosity as to the construction of traps, closets, &c., than anything else.

*The Water Supply of Towns and the Construction of Waterworks.* By W. K. BURTON. London: Crosby Lockwood and Son. 1894.

THE author is Professor of Sanitary Engineering in the Imperial University, Tokio, Japan, and consulting engineer to the Tokyo Waterworks, and he states that the volume is largely based upon his own practice, and the conclusions expressed therein are the result of careful study of the various questions dealt with. He hopes that the work may prove of special interest to Japanese students, but the matter which applies to Japan alone is relegated to foot-notes, so that the continuity of interest to the general reader is not interfered with. The work consists of some 280 pages, and is copiously illustrated.

The author states that from the time—nearly three centuries ago—that Tokio, the capital of Japan, was supplied with water by the Tamagawa Canal, supplemented by a complete system of ingenious wooden pipes of square section, till about the beginning of this century, it had a better supply of water than either London or Paris, or probably any town in Europe of which the natural supply was not exceptionally good. It must be remembered that wooden pipes for the distribution of water were used in London up to about 1820, and pieces of these pipes are constantly being dug up in the streets at the present day, most of them being trunks of trees bored out and fitted end to end with taper joints.

With regard to the requisite supply of water per head of population, the author alludes to the great difficulty of making exact calculations, and considers past practice the only trustworthy authority. It has been possible in some cases to reduce the mean consumption, even in water-closet towns in Europe, to as little as two cubic feet per head per day for domestic supply; while in the case of American towns the figures approximate occasionally to 20 cubic feet per head per day.

In the earlier chapters the author deals with the gauging of streams and rivers, and the estimation of storage capacity, and refers to actual works to illustrate his subject. In dealing with dams he refers to the use of concrete for the bulk of the dam, and cites the case of the Tytam Waterworks, Hong Kong. Mr. James Drage, the engineer, finding Chinese masons untrustworthy, or unable to do a style of work of the excellence necessary for masonry dams, constructed a considerable dam entirely of rubble concrete, with a cut stone facing. This has already been in existence several years, and has given satisfaction. The chapter upon the filtration of water is very complete, and the details of construction are well illustrated; the author states that beautiful sands for filtration are found in Japan. Two sands in particular, from Niijima and Shikene, in the district of Idzu, are the most perfect sands for the purpose which he has ever seen. These are pure white sands with occasional little black spots. When looked at with a magnifier, the white grains are seen to be as clear and transparent as glass, and the black spots consist of magnetic oxide of iron.

The report made on the "Filtration of River Waters for the Supply of Cities, as Practised in Europe," by James P. Kirkwood, is justly spoken of by the author, who says that since the date of this work most of the matter which has appeared in text books, &c., has been copied from it, usually without acknowledgment. At that date the English filters were considered deficient as regards any arrangement for regulating the precise flow from each, or the precise head of water on each filter while in action. In considering the question of obtaining fresh water by driving a tunnel through porous strata and parallel to the course of a river, the author points out that in most cases the water in the gallery is not obtained direct from the river except in very dry weather, but by the interception of underground streams flowing to the river. In Japan, however, where commonly the rivers have been embanked, so that in many cases the beds are above the surface of the surrounding land, this source of supply would not be available, and the river itself would probably be drawn upon.

At the end of the book is an appendix by Professor John Milne, F.R.S., entitled "Considerations Concerning the Probable Effects of Earthquakes on Waterworks, and the Special Precautions to be taken in Earthquake Countries." As applied to the dams of reservoirs, the investigations point to the advisability of using the English rather than the American plan; also there is a strong argument for the adoption of a dwarf wall as a "breakwater" along the top of an earthwork dam in an earthquake country, and it may be further advisable to pitch with stones the top and lower slope of the dam, as well as the upper slopes, to prevent the action of the water on the surface if earthquake waves were formed. The work should be especially valuable to civil engineers engaged in work in Japan, but the interest is by no means confined to that locality.

## THE ELECTRICAL ACCIDENT IN CANNON-STREET.

On Saturday, the 10th November, 1894, an electrical accident took place in Cannon-street, at the point where Budge-row and Walbrook branch off. This accident was of such a serious nature that a Board of Trade inquiry was held by Major Cardew at Winchester House, Old Broad-street. The proceedings were opened at 11 a.m. on Monday, the 19th inst. Mr. R. W. Wallace represented the City of London Electric Lighting Co. Mr. Baylis appeared for the City Commissioners of Sewers, and Mr. R. Griffiths for the Aldermen and City Commissioner of Police. In this inquiry the evidence of witnesses was taken, but not on oath. The witnesses were all allowed to be present while the inquiry was being held, which seems, in our opinion, to tend to a certain degree of similarity in the accounts which were given of the details of the case. Hall 174 does not appear very well adapted for the purpose of such an inquiry, as the noise caused by persons passing in the corridors somewhat interferes with the comfort of those occupied in the case.

Time would have been saved to a large extent, and a more accurate idea obtained of the evidence if a large, boldly-drawn plan of the site had been used, and the witnesses asked to point out the spots by means of a pointer. Without this aid it was often uncertain as to which side of the street was referred to by a witness, and the exact spot could not be ascertained within a few yards. As will be seen later on, it is very important to be able to determine with certainty where the particular occurrences took place.

The first witness was one George Clark, who stated that he was driving a brougham belonging to Mr. Boutland, and at about one p.m. on Saturday, November 10th, he was passing along Cannon-street in an eastward direction and turned into Budge-row. Hardly, however, had the horse turned the corner when it fell on its knees, and then on its side, bled at the nose, and after struggling for a few minutes, died. The witness jumped off the box and immediately received a shock which he described as like pins and needles. The site of the accident is shown in Fig. 1, and the position of the horse after falling is also shown. The carriage-way at this point is paved with wood, and there is no plate to be seen. It appears that the surface of the road was very wet at the time. The witness stated that he had not been able to work since the accident, but he did not see any smoke or hear any noise when the mare was killed. The position of the junction boxes is shown on the plan, and they are marked A, B, C, and D, and the mains belonging to the City of London Electric Lighting Company cross Cannon-street and Budge-row, connecting the boxes together. Box A is at the corner of Dowgate-hill, next to Cannon-street station; box B is at the corner of Budge-row and Cannon-street; box C is at the door of No. 20, Budge-row; and box D is at the corner of Walbrook, just outside a hosier's shop.

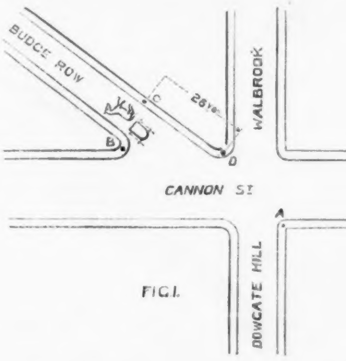

FIG. 1.

James Hutchings, warehouseman, employed at 21, Budge-row, was standing at the loophole looking into Cannon-street, and saw the horse fall. He went to try and assist and received a powerful electric shock when he approached the horse, and was brought to the ground. He has been under medical advice since. About ten minutes after he saw the horse fall he heard an explosion, and, on looking at the junction box outside No. 20, Budge-row, he saw the lid was blown about 2ft. into the air, and a blue flame escaping, with a good deal of black smoke. This witness stated that he heard a rumbling noise underground while the horse was lying in the street.

A postman stated that he was going along Cannon-street, and when he reached the corner of Budge-row he received a shock. This he explained occurred when he had one foot on the cover of the junction box B and one off. The shock did not cause him to fall. A few minutes after this he heard an explosion, and was struck by a piece of stone and was hurled across Walbrook. None of these witnesses had smelt any escape of gas before the explosion. It turned out in the course of the inquiry that after the death of the horse there were two separate explosions. One at box C, whence bluish flames were seen to issue, and thick black smoke, which lasted several minutes. The cover of the box did not appear to be injured. The other explosion occurred almost simultaneously at box D, and this caused much more danger, as four or five persons were standing either upon or close to it. Several witnesses were called who described the occurrence in the same way, and it appeared that two men were so injured that they were still unable to leave their homes at the date of the inquiry.

Mr. Haslett, a mining engineer, of 64, Cannon-street, said he received a smart shock when crossing the road, and he saw the explosion and heard three reports in close succession. He was taken to Guy's Hospital. Mr. Withers, at the hosier's shop at the corner of Walbrook, said: The explosion in box D broke the lid of the box into pieces, and forced the brickwork inwards, and the kerbstone outwards into the road, it also broke a window and a shop blind. One of his assistants had smelt a smell as of india-rubber burning in the basement of the shop about an hour before the explosion took place.

Various policemen were then called to give evidence as to previous explosions in the City of London. One stated that while he was on duty on October 14th, 1892, in Great Tower-street, at 8.55 p.m., he heard the noise of an explosion near 17, Great Tower-street, and when he went to the spot he saw a man apparently insensible. Two street junction box lids, about five yards apart, were displaced, and he saw the lid of one box at a height of about 20ft. in the air. Another policeman stated that on January 8th an explosion took place in a test box in front of No. 3, St. Paul's-churchyard, blowing the cover into the air. A report of a similar occurrence at Creed-lane was also given.

Mr. David Cook, chief engineer and manager to the City of London Electric Lighting Co., was then examined, and he produced a diagram showing all the mains affected by the accident. He said that the cause of the accident was the crossing of two high-pressure cables, which were being tested and put to work for the first time. One of these cables was for the supply of current to the Watling-street transformer station, and the other for the Milk-street transformer station. The Milk-street cable was by mistake put into the terminals for the Watling-street cable at the Bankside generating station, while the Watling-street cable was laid, so that its inner conductor touched the lead covering of a third cable. The cables were of the concentric type. For convenience current was switched on to the Watling-street cable from the transformer station. When the signal was given the attendant at the transformer station switched on, and as the inner conductor of the cable was against the lead covering of the other cables, therefore all the inner conductors of the high-pressure service were put to earth, thus throwing an unusual stress upon the insulation of the primary mains. The actual cause of the breakdown appeared to be the abrasion of the outside covering. When the attendant discovered the breakdown he switched out the cable, but before this was done the leak had developed into a short circuit, and this fired some gas which had collected in the box and caused the two explosions. Mr. Cook explained that since the explosion which occurred in St. Paul's-churchyard the company had had men constantly looking for leakages of gas. Four times since March last they had written to the gas company about leakages in Cannon-street within 100 yards of the spot where the explosion took place, and since January last they had written to the gas company eighty-eight times, calling attention to similar leakages all over the City. He stated, however, that the gas company had attended promptly to the communications sent to them. The gas leakages were so important that he intended to propose to his directors a system for ventilating the conduits which would cost about £2000; and he desired to draw the attention of the Board of Trade to the responsibility of the gas company in respect to these explosions.

Major Cardew said that as the electric light company had arrived after the gas company, it was the business of the former to see that gas did not leak into the electric light conduits.

The inquiry was continued last Tuesday, and Mr. Cook continued to give evidence. The cable which actually broke down was the one feeding the Benetfink sub-station, and this only broke down in the place already alluded to—that is, in box C, outside the offices of the Liberator Company in Budge-row.

Major Cardew remarked that if the only method of dealing with such accidents was by means of a fuse which might allow 2000-horse power to pass, then serious consequences might ensue. It appeared that there were about 46,000 lamps wired in the district supplied by this cable, and that 70 per cent. of these have been on at one time. Such accidents as the present one had taken place through arcs being formed, and Mr. Cook did not know of any means for cutting out the arc. It must be remembered that when the scheme of supply is completely carried out there will be a separate pair of primary mains from the generating station to each sub-station, and the system of interconnection of mains would not be continued. At present the sub-stations are connected together.

Orders have been given to cover all the parts of the cable between the ends of the pipes with copper strips securely fastened to the iron pipes. The present system is to run the high-pressure cables in iron pipes and the low-pressure mains in Callender conduits covered outside with sheet iron. The high-pressure cables are of the concentric type. The new cables are lead-covered, but not armoured. The boxes are constantly inspected to see that all is right. Mr. Cook said that far more persons were injured by slipping on orange-peel than were ever likely to be injured by accidents caused by electricity.

Much attention has been devoted to the question of the proper ventilation of the electric conduits, and, in reply to Major Cardew, Mr. Cook said that if the Commissioners of Sewers would give permission to erect ventilating standards, he had no doubt all the present difficulties could be got over. Mr. Cook's suggestion was that the guard posts at the corners of the streets should be used as inlets and outlets for air.

Mr. G. L. Foulger, distributing engineer to the Gas Light and Coke Company, then appeared, and stated that it was quite incorrect to say that the explosions were caused by the escape of gas, as he had had careful tests made in the locality immediately after the accident, and no traces of gas were found. His own suggestion as to the ventilation was that the arc lamp posts should be used as ventilating columns by placing, say, a 2in. iron pipe inside the post, connecting the pipe to the electric conduits below, and by means of a bend to an opening at, say, 10ft. above ground level, so that the mixed gases would pass out about 10ft. below the arc light, and therefore would pass away without danger. In order to prevent the gas lighting back, he would fill the lamp posts with earth or sawdust.

Although on the first day no witness had appeared who could say that he smelt gas at the time of the explosion, yet the Electric Lighting Company are so satisfied that gas alone was the cause that they employed Mr. Wagner, an analytical chemist, of Leadenhall-street, to make a chemical analysis of gases collected from the test-boxes, and this was done on the evening of the 19th. It must be remembered that the covers of these boxes consist of iron frames filled in with concrete, so that it was necessary to drill a hole through the cover of each box. Two samples were taken from one box, each sample being about 1½ pints, and one sample of about four pints from the other, all by means of an aspirator. These samples were tested to discover the presence of coal gas, and no trace could be found in box D at the corner of Wallbrook, while in the sample from the Dowgate-hill box A the presence of 12 per cent. of coal gas was detected.

It has been very generally thought that the accident to the horse was caused when its fore feet were placed on the exposed surface of a street junction box, while its hind feet were on the surface of the ordinary carriage way. But this does not appear to have been the case, as the driver distinctly asserted that the horse did not stand upon a junction box at all. The inspection or junction boxes are in the footway, so that another explanation must be sought for in the presence of a considerable difference of potential between two points on the surface of the carriage way, say about 4ft. apart. The much more serious effect of an electrical shock upon a horse than upon a man must be due, in the first place, to the far better contact which is made with the ground through horse-shoes than through boot soles, and also to the possibility of a greater difference of potential occurring between the fore and hind legs of a horse than between the two feet of a man. It is to be hoped that the Board of Trade will authorise further tests under varied conditions, as it is obvious that at present the dangers of the streets are increased by the use of buried conductors at high pressure.

## CANET GUNS AT YALU.

M. Canet has received a letter on the behaviour of his guns on board the Japanese fleet in the battle with the Chinese, from which we give the translation of an extract:—

> Tokio, Sept. 29th, 1894.
>
> With regard to the naval battle which took place in the Yellow Sea, the Chinese fleet consisted of fourteen ships, six torpedo-boats, and the Japanese fleet of eleven warships and a packet vessel converted into a cruiser, on board which was the Admiral Kabayama.
>
> The battle began at a quarter to one in the afternoon, and lasted till nightfall, when it became impossible to lay the guns. In this fleet were the Matsushima, carrying the flag of Vice-Admiral Ito, the commander-in-chief; the Itsukushima, and the Hashidate. Your three guns behaved well in the battle. After five hours of bloody fight, the enemy's fleet lost the Ping Yuen armoured ship, of 2830 tons, two cruisers of the class Ching Yuen, of 2300 tons, and the Tshao Young, of 1350 tons—that is to say, four ships. Three others were set on fire, which the crews were probably able to extinguish.
>
> Happily we have not lost a single ship. The Matsushima appeared to suffer the most, but the big Canet gun has escaped injury, except that a bursting shell has slightly injured the breech mechanism. One of the 12 cm. guns in the fore part of the ship has been bent by a shell. This is likely to be very trying, because the gun port must be injured.
>
> The Ping Yuen was crushed by the blow of a 32 c.m. projectile, which struck the water-line in the after part. The armoured deck was probably perforated, because it was observed that the ship began to sink stem first, and actually sank end on, a phenomenon which has never before been witnessed.
>
> To-day I am pressed with work, and cannot complete this letter until the next mail.

With regard to this extract, it may be noticed that the King Yuen, which was the vessel actually sunk, is mistaken for the Ping Yuen. She has in a former Japanese account been mistaken for the Lai Yuen. The fact is that these three ships are sisters, and were all present in the action. It may also be observed that the Japanese are stated to have ceased firing not from failure of ammunition, as we have hitherto assumed, but because the light became insufficient to lay the guns. At a long range doubtless this might be the case, but we still think it probable that failure of ammunition was the principal cause for terminating the action. The expenditure of shells seems to have been very great. The Chinese ships were struck in hundreds of places on their armour, and apparently peppered indiscriminately. Seeing that the fighting was on the move and at long ranges, this means also a very great quantity of ammunition thrown away. The Japanese officers may not like to admit it, but this fact, coupled with the circumstance, if it can be credited, that the Chinese endeavoured to follow the Japanese and continue the combat, points, we think, to the very natural conclusion that we drew, that the Japanese quick-firing guns had but little ammunition left. This in no way affects the fact that M Canet has every reason to be satisfied with the behaviour of his guns. The 32 cm. gun is abundantly able to perforate the belt of the King Yuen—which consists of 9½in. compound armour—with armour-piercing shell; indeed, common shell, if they are made of steel with pointed heads, might even do this, and these would be the most powerful projectiles for the attack of such a ship. The Japanese themselves, however, only know what they fired. Common shell of cast iron, or even of steel, with ordinary heads with fuse holes, would not perforate the belt, but might burst close to it and do great damage, while an armour-piercing shot without a bursting charge would hardly sink the vessel by simply perforating her belt.

The Laundry Exhibition.—In our report on the machinery at this Exhibition reference was made to Messrs. Joseph Evans and Sons' steam pump, which, by an error, was mentioned as a "Cornish" steam pump, with Tonkin's patent valves—tappet motion. This should have been "Cornish" steam pump, with Tonkin's patent valves, having *no* tappet motion.

Institution of Electrical Engineers.—At the sixth annual dinner of the Institution of Electrical Engineers was held on Wednesday evening last at the Freemasons' Tavern, the president, Mr. Alex. Siemens, in the chair, we heard a good deal about the "supremacy" of electricity and the wane of steam. This sounds pretty, but is at the same time a little irreconcileable with the statements made the same evening by Dr. H. E. Armstrong, president of the Chemical Society, one of which was that electricians were too much the slaves of the dynamo; in other words, of power. Among those present were Mr. Bryce, M.P., President of the Board of Trade; Sir John Pender, M.P., Sir Robert Rawlinson, Mr. W. H. Preece, General C. E. Webber, Professor W. G. Adams, Dr. John Hopkinson, Professor W. Crookes, Professor Hughes, Mr. C. Spagnoletti, Mr. W. H. M. Christie, Astronomer Royal; Professor A. B. W. Kennedy, Sir David Salomons, Bart., Mr. R. E. Crompton, and Professor J. Perry.

Boilers and Thermal Storage.—In the Cantor lectures delivered by Professor Unwin at the beginning of last year, before the Society of Arts, he described the system of "Thermal Storage," which had lately come under his notice. In our issues of the 20th and 27th of January, 1893, we also referred to this matter, and described its mode of operation. We have been informed lately that the first set of plant was put to work about a month ago; and, although this time is too short to arrive at the actual saving in fuel, it has afforded an opportunity of definitely demonstrating one of the advantages claimed by the system, viz., that the water is purified before being put into the boiler. In the instance to which we refer, the boilers were working for two months before thermal storage was put in—owing to delay in completion of the plant—and as the water available for feeding the boilers was exceedingly hard, an unusually large amount of deposit was found when the boilers were stopped for cleaning out. This deposit in the boilers has now ceased, the whole of the deposit being thrown down in the thermal storage vessel, out of which it is blown once a day, and where, of course, owing to the absence of the baking temperature existing in the boiler, it has not been able to harden. The evaporation without the thermal storage system was already very good; but even on the high duty obtained a considerable saving has been effected in fuel, although we are not in a position to give accurate figures at present.

# A REMARKABLE BOILER EXPLOSION

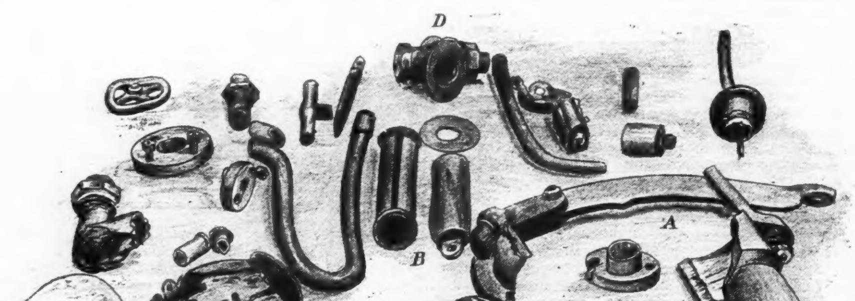
## A REMARKABLE BOILER EXPLOSION.

The accompanying engravings are reproduced from a Board of Trade report on a boiler explosion which took place at Woodside Ironworks, Dudley, on the 27th of July, 1894. It will be seen that the effect on the boiler was what might have been expected if a moderate charge of dynamite had been exploded inside it. It is by no means easy to account for this general smash up. It is extremely difficult to explain the successive explosions with great rapidity of nearly all the boilers in a battery of twenty which is said to have occurred recently at an ironworks in the United States.



"The Engineer" Fig. 3. Swain Eng.

The boiler, the remains of which we illustrate, was of the cylindrical vertical type, and was made throughout of iron. The shell was 4ft. 4in. in diameter and 8ft. 2in. in height, and was made up of two rings of plates with four plates ⅜in. thick in each ring. The top, which was flat, was made up of three plates, the outer portions of which were ½in. and the central portions ⅜in. thick. Its outer edge was attached to the shell by means of an angle-iron ring 3¼in. by 3¼in. by ½in., and its centre was secured to the uptake by an internal angle-iron ring 3¼in. by 3¼in. by ⅜in. The fire-box was 3ft. high and 3ft. 9¼in. in external diameter. Its sides were made up of two plates each ⅜in. thick. Its bottom was attached to the outer shell by means of a ring ⅜in. thick, the vertical flanges being 2½in. deep, and the horizontal portion 3in. in breadth. The uptake was 9¼in. in internal diameter and ⅜in. thick. Its vertical seam was welded, and its lower end was secured to the fire-box crown by means of an angle-iron ring. The boiler was single-riveted throughout by rivets ¾in. in diameter pitched 2in. apart.

The mountings consisted of one safety valve loaded by means of a lever and spring balance, one steam pressure gauge, one injector, one steam pipe, one glass water gauge with the usual fittings, two test cocks, one blow-off cock. There were one manhole door 16in. by 12in., and three mud holes. The boiler was broken into fragments, which were hurled great distances. The fracture commenced in the shell-plate near the firehole, and having spread, ran in various directions horizontally and vertically, dividing the shell into numerous pieces. One man was killed and several injured. The explosion was caused by over-pressure, the safety valve being inoperative at the time by reason of the nut of the spring balance having been screwed down so as to prevent the valve from lifting. The working pressure was 25 lb. only on the square inch.

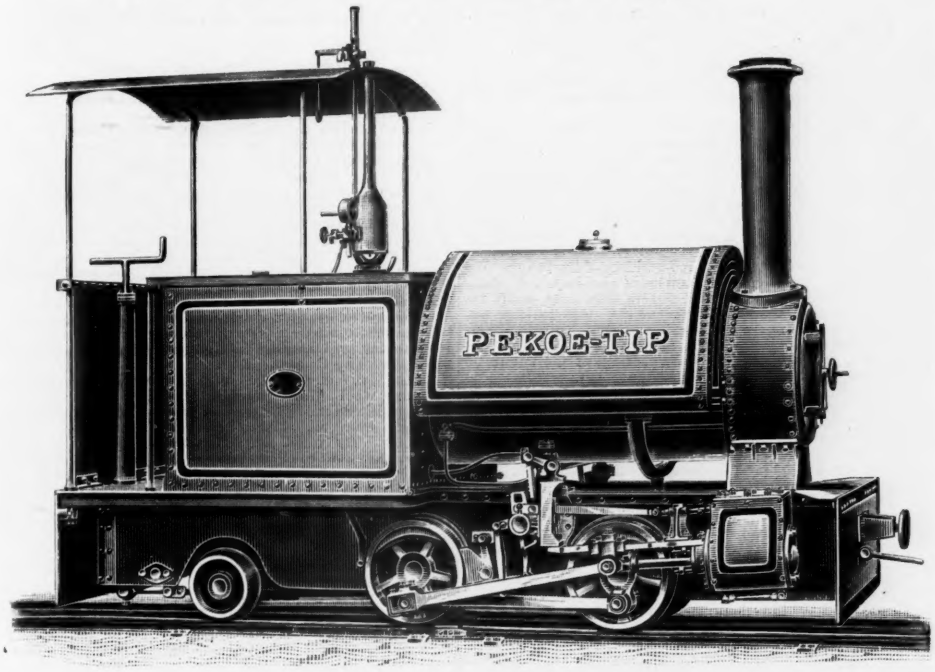
Fig. 1 is a view of the top of the shell after the explosion. This was hurled about 25 yards. Fig. 2 is a view of the fire-box. The main piece A remained in the position in which the boiler had stood. The pieces marked B, C, D, and E are portions broken from the side of the fire-box by the explosion. Fig. 3 shows the fragments of the boiler mountings as found after the explosion:—A, portions of the valve chest, the valve lever, and joint; B, the outer and inner case of the spring balance; C, remains of the steam gauge; $C_1$, remains of the steam gauge dial; D, the blow-off cock. Fig. 4 shows portions of the shell plates as they appeared after the explosion. The pieces marked with the large letters D were hurled about 69 yards; F was thrown about 40 yards. The small letters and the figures were marks used for identifying the various pieces when fitting them together after the explosion. The numbers 10 and 11, for instance, indicate that the vertical seams near which they are placed coincide with the positions in the top plate denoted by the same numbers.

---

THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—On the 15th inst. this Society visited the works of Messrs. Bullivant and Co., Isle of Dogs, where the processes of making steel wire cables and ropes, torpedo-catching nets, and wire-netting is carried on. The members of the Society were taken over the works by one of the partners. They were shown every detail of the manufactures, from the testing of the wires before they are made up into ropes to the testing of a finished heavy cable. The various machines in the cable shop were carefully explained as was also the process of galvanising the wires. The process of making the torpedo-catching nets was examined. The ingenious wire-net making machines were next examined, machines which had made many thousands of miles, sent to all parts of the world. The testing-house in which tests are made by special machines—designed by a member of the firm—of the finished cables was inspected, and a portion of a 4in. cable was tested to destruction. The machines for testing the wires before they are made into ropes were also in this house, the testing being both for tensile stress and torsion, and the method of conducting these was gone into. Many interesting details as to cables made and making were given.

## NARROW GAUGE LOCOMOTIVE

MESSRS. W. G. BAGNALL, STAFFORDSHIRE, ENGINEERS



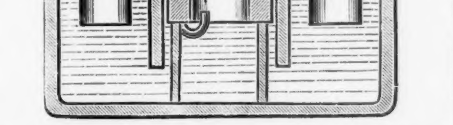
### NARROW GAUGE LOCOMOTIVES.

We illustrate above a little locomotive constructed by Messrs. W. G. Bagnall Limited, Stafford. The dimensions are as follows:—Cylinders—diameter, 5½in.; stroke, 9in.: wheels, four-coupled—diameter, 2ft.; centres, 3ft.; wheels, bogie, diameter, 1ft.; total wheel base, 6ft.; boiler, Siemens steel; fire-box, Siemens steel, circular; tubes, steel, 1½in. diameter; heating surface—tubes, 80 square feet; fire-box, 10 square feet; total, 90 square feet; grate area, 3·28 square feet; fuel capacity, 7 cubic feet; water capacity, 140 gallons. The engine is made for a 2ft. gauge, and is fitted with Baguley's patent valve gear.

### NEW GALVANIC ELEMENT.

At the first annual meeting of the German Electro Chemical Society, which was held at Berlin on the 6th of October last, a new form of galvanic element was brought forward by Dr. Borchers, of Duisburg, which is a notable advance in the direction of the conversion of the chemical energy of fuel into electricity without employing an intermediate thermal transformation. The method is based upon the absorptive power of an aqueous solution of cuprous chloride for carbon monoxide and oxygen, a well-known reaction which is utilised in the analysis of gases, and proceeds in the following manner:—

Carbon monoxide CO forms with cuprous chloride $Cu_2\ Cl_2$, the compound $Cu_2\ CO\ Cl_2$, which in the presence of water tends to split up into metallic copper, hydrochloric acid, and carbon dioxide. Thus



$$Cu_2\ CO\ Cl_2 + H_2O = 2\ Cu + 2\ HCl + CO_2.$$

On the other side, cuprous chloride in the presence of atmospheric oxygen and hydrochloric acid passes into cupric chloride and water, or

$$Cu_2\ Cl_2 + 2\ HCl + O = 2\ Cu\ Cl_2 + H_2O.$$

After the taking up of carbon monoxide on one side, and oxygen on the other, the reaction between cupric chloride and metallic copper comes into play. $Cu\ Cl_2 + 2\ Cu = Cu_2\ Cl_2$, whereby the electrolyte is regenerated. The only permanent change, therefore, is the conversion of carbon monoxide into dioxide, which is effected by atmospheric oxygen as in ordinary combustion, but with the difference that the combustion being a "cold" or wet one, as it is effected in a fluid, the surplus energy resulting from chemical action is converted not into heat but into electricity. The result is the same when mixed gases containing hydrocarbons and hydrogen are used instead of carbonic oxide, the products in this case being carbon dioxide in water.

The circumstance that only the gases, and not the metallic parts of the battery, are acted upon and dissolved in the electrolyte renders it possible to use electrodes of copper on the side that the gas is introduced, *i.e.*, the anodes in the electrolytic cell itself may be made of some metal serving as well as a conductor, the cathode being made of carbon or platinum. The experimental cell, with which Dr. Borchers has demonstrated the feasibility of making a battery based on the above principles is represented in the annexed figure.

A glass vessel of rectangular section is divided into three parts by glass plates reaching nearly down to the bottom. In each of the outer divisions a tubular copper bell passes down through an air-tight cover into the electrolyte and serves as an electrode as well as for the introduction of the gas into the solution which is brought in through the tube at the top. The cathode in the central division is a carbon bell into which air is introduced by the curved pipe at the bottom; the permanent gases, however, are taken off by the pipes through the covers on the anode sides. The electrolyte is a solution of cuprous chloride acidified with hydrochloric acid, which has been found to be preferable to the alkali solution used at first.

The first experiments were conducted with impure carbon monoxide containing a notable quantity of carbonic acid, when a current of 0·5 ampère was obtained with an interposed resistance for measuring. Subsequently, as a matter of convenience, coal-gas containing 7 per cent. of carbon monoxide was substituted, and the absorptive power of the outer cells was increased by filling them with copper turnings, when, with a low resistance, 0 64 ampère was obtained, which, by increasing the external resistance, became constant at a maximum potential of 0·56 volts, which as the theoretical tension—after allowing for all necessary reactions going on in the battery—corresponding to the reaction $CO + O = CO_2$ is 1·47 volts, represents a transformation of 38 per cent. of the fuel into electricity in the most favourable condition, while the energy of the lowest result was 26 per cent.

The experiments have extended to the substitution of coal in a powdered state for carbon gases in the battery, with results which, however, are not so good, the highest tension attained having been 0·3 volt, the theoretical yield of $C + 20 = CO_2$ being 2 volts, or a proportion of 15 per cent. As, however, the intensity of the current rapidly fell off in spite of the maintenance of energetic movement in the electrolytic fluid, the experiments in this direction have for the time been given up.

When, however, it is remembered that only about 12 per cent. of the total energy of coal can be realised by the agency of steam, and 20 per cent. by the gas engine, the figures realised by this rough experimental apparatus are sufficiently remarkable, and we may agree with an opinion expressed at the meeting that should it be found possible to construct this battery in a practical working form it is likely to effect a revolution in manufacturing industries at least of equal importance to that caused by the invention of the steam engine for the production of energy at a low cost, the new battery taking the place of the boiler, and the electromotor that of the steam engine.

In the paper sketches are given of two forms of the battery as it is proposed to construct it on the working scale. In these the anode cell is a V-shaped copper trough, partially filled with copper scrap and turnings, while the cathodes are contained in perforated stoneware cells filled with fragments of coke or gas carbon, the current being collected by a rectangular bar of carbon running along the bottom of the inner cell. The cells are intended to be arranged in series one above another, with the electrolytical fluid circulating by gravitation from above downward.

Two first-class Russian battleships, of 10,960 tons and 10,600-horse power, were launched last week on the Neva, where, had the events been delayed much longer, the ice would have blockaded the vessels for the winter. These ships have 15·8in. belts, and on each of their two principal turrets 10in. armour. Each turret has a couple of 12in. guns. There are four other turrets, each with 4·7in. armour and a pair of 8in. guns, and there are twenty-four smaller guns. The ships are named Poltava and Petropaulovsk. The expected maximum speed is 17·5 knots. The new German third-class battleship Odin, previously known as "V," was launched on the 3rd inst., by Count Haugroitz. She is similar to the Siegfried, Beowulf, Frittijof, Hagen, Heimdal, and Hildebrand, and to a vessel, "T," still unlaunched at Kiel. These ships were originally designed as coast defence vessels, but are now regarded as suitable for a wider sphere of action.

## LETTERS TO THE EDITOR.

(*Continued from page 447*)

### TRAIN SPEED.

Sir,—The question of train speed is always an interesting one; interesting to those specially engaged in working the vast traffic now daily carried upon our railways, and interesting to the general public to utilise the trains, and which may without exaggeration be said to include everybody. In countries outside Great Britain, the demand for high speed seems of late years to have been pushed forward with more than usual emphasis. Whereas so late as six years ago an average booked speed of fifty miles an hour was only to be found within the British Isles, we now find America, France, and Germany all claiming the right to be placed within the fifty miles an hour category. Indeed, I do not doubt that if severe gradients do not prove too great a hindrance, we shall before long be told that Japan claims a premier position with her "Flying Chinee" at fifty-five miles an hour.

Meanwhile, we in England look upon the progress made in the same period with somewhat doubtful eyes. Fifty-six miles an hour is still our maximum booked speed. Our Scotch expresses have no doubt greatly improved in one respect, namely, the reduction in the total time occupied from point to point; this has, however, been chiefly effected by cutting down stops. The heavy loads usually associated with these trains seem to preclude a higher average speed than fifty-three miles an hour. The Great Western during the past six years has increased its express mileage from 8000 to 9000; but the solid old Dutchman still tramps along at fifty-three miles an hour between Paddington and Swindon. In an article on this subject in your issue for October 26th, you referred to the great increase in the weight and dimensions of our express engines. We now find Caledonian, Midland, Lancashire and Yorkshire, and South-Western, all running 19in. cylinders; we have Greater Britains and Worsdell compounds weighing approximately 90 tons when fully equipped; and the Great Western now go one better with a cylinder 20in. in diameter.

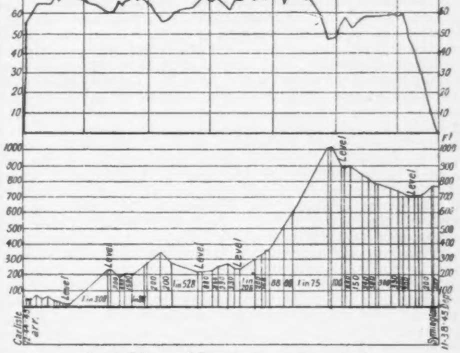
Now the questions which present themselves are: (*a*) Have trains so increased in weight as to necessitate these ponderous productions? (*b*) Are those engines capable of running at a higher speed than their predecessors?

Speaking generally, I may say without hesitation that the answer to the first question is in the affirmative. It is no doubt true that on some lines there is very little difference in the weight of trains now and ten years ago. On the Great Western, though the individual coaches are much heavier, so many more trains are now run that the actual weight is even less than it used to be. Expresses totalling up to 300 tons used to be quite a feature of the Great Western; now, as the table of train loads published by you, Sir, on November 2nd shows, the maximum may be taken as about 200 tons. On the London and North-Western loads have increased all round. Take the Scotch mail, which used to be the heaviest train. In 1864 it weighed 54 tons; in 1874, 75 tons; in 1884, 165 tons. Now, in 1894, the corridor train, which is probably the heaviest express in the Kingdom, is made up as follows:—

*W. C. J. S. Corridor Train.*

| | | Tons. | Cwts. |
|---|---|---|---|
| 1. | Eight-wheel brake van with two compartments .. .. | 22 | 10 |
| 2. | ,, third-class with lavatories .. .. .. .. | 22 | 10 |
| 3. | Twelve-wheel third-class dining car.. .. .. .. .. | 30 | 10 |
| 4. | ,, first-class dining and kitchen car .. .. | 33 | 10 |
| 5. | ,, ,, dining car .. .. .. .. .. .. | 30 | 10 |
| 6. | Eight-wheel first-class with lavatories .. .. .. .. | 22 | 10 |
| 7. | ,, composite ,, ,, .. .. .. .. | 22 | 10 |
| 8. | ,, third class and brake van .. .. .. .. | 22 | 10 |
| 9. | ,, composite with lavatories .. .. .. .. | 22 | 10 |
| 10. | ,, third-class and brake van .. .. .. .. | 22 | 10 |
| | Total .. .. .. .. .. .. .. .. .. .. | 257 | |

During the summer months this train has frequently totalled 300 tons. In fact, it may be safely said of all L. and N. W. expresses during the summer months, that they are loaded to their fullest capacity, and I think it very doubtful if the Precedents could successfully tackle the loads without a great deal of pilotage.



*Load-4 Bogies 3 Six-wheelers 1 Four-wheeler.*

On the Midland and Great Northern I likewise note a steady increase in the weight of the best trains. The 8 p.m. Great Northern Scotch express has, during the busy time, often to be run in three portions, and the 10 a.m. has been booked in duplicate —10 and 10-8—for the best part of the last six months. As for the East Coast Corridor train, the normal load is approximately: Two six-wheel brake vans, three six-wheel composites, one six-wheel kitchen car, and two eight-wheel bogie dining cars. Total weight about 136 tons. During the summer this train is run in duplicate as far as Newcastle. The train which ran into the buffer stops at St. Pancras station on August 12th last, may be taken as an average load for a Midland express. It was made up as follows:—One Pullman car, one N. B. third, one M. S. J. S. van, one N. B. composite, one Pullman sleeping car, two Midland composite, two M. S. J. S. composite, one Midland third, two vans twelve coaches; total weighing altogether 153 tons. From these figures it will be seen that individual coaches are steadily increasing in weight, though we are still a long way behind our American cousins, who deal in 80ft. cars weighing something like 50 tons. The following are the heaviest now run in Great Britain:—

| | Tons. |
|---|---|
| M. S. J. S. corridor dining 12-wheel bogie .. .. .. .. | 33½ |
| W. C. J. S. ,, ,, ,, ,, .. .. .. .. | 33½ |
| E. C. J. S. ,, ,, 8-wheel ,, .. .. .. .. | 25 |
| South-Eastern 12-wheel bogies .. .. .. .. .. .. .. | 26½ |
| Manchester, Sheffield, and Lincoln 12-wheel bogies .. .. | 25 |
| Great Western corridor 8-wheel bogies .. .. .. .. .. | 24 |
| London and South-Western 8-wheel bogies .. .. .. .. | 22 |

The difficulty of the whole matter lies in the fact that during three or four months in the year trains are about twice the weight of those run during the remaining eight. The engines, of course, must be constructed with a sufficient margin of power to efficiently work the heaviest possible traffic. The result is that very light trains have frequently to be run with an excess of engine power out of all proportion to the work required. I remember on one occasion recently travelling in a West and North Severn Tunnel express. From Bristol to Shrewsbury the gradients are very severe—1 in 80, 1 in 75, and 1 in 50. The train consisted of ten eight-wheel bogie coaches, weighing close upon 200 tons. The engine to Shrewsbury was an old one, having 17in. cylinders and 6ft. 6in. coupled wheels. From Shrewsbury, where the train was divided, a London and North-Western compound of the latest type, "John Hicks," took on four coaches over the comparatively easy road to Liverpool. In this case the power and weight of the engine was out of all proportion to the load, which probably did not weigh as much as the engine itself. But the 17in. engine had the aid of a pilot up the banks, a proceeding which might have been avoided had an engine as powerful as the "John Hicks" been employed.

Turning now to the second question—that of high speed. We know that years ago on the occasion of a special speed trial eighty miles an hour was obtained. Latterly, I believe, higher speeds have been noted in everyday work; I fancy Mr. Rous Marten could give us some interesting information on this point. Personally I have never noted with certainty a higher speed than 78½ miles an hour. We have Mr. Worsdell's authority for a speed of eighty-six miles an hour with one of his giant locomotives; and in America there seems positively to be no limit to the authenticated records. But whatever figure may represent the true maximum speed of the modern locomotive, there can be no doubt that it is capable of reaching that maximum with a much greater load than was possible to the earlier engines. Further, they are capable of tackling steep banks in a style quite beyond the powers of their predecessors; and the possibility of obtaining a high average speed is increased accordingly.

The race to Edinburgh in 1888, though decried by a good many people blessed with over sensitive nerves, taught us a great many valuable lessons. It showed us, first, that our lines are with absolute safety adapted to a speed greatly in excess of that hitherto imagined possible. A considerable variety in the type of engine employed gave us some idea of their respective merits. From Euston to Crewe the West Coast train was worked by an old engine of the Waverley class. The best performance on this run was:—Euston to Crewe, 158 miles in 166 minutes, giving an average speed of fifty-seven miles an hour. Had a modern engine been employed to work that section there is no doubt double the load—the West Coast train weighed 77 tons—might have been taken at an average speed of sixty miles an hour. The East Coast train, which weighed 120 tons, ran at an average speed of sixty miles an hour on at least three occasions, namely: King's Cross to Grantham, 105½ miles in 105 minutes; York to Newcastle, 80¼ miles, twice in eighty minutes. These trains were worked by modern engines.

In your issue for March 13th, 1891, you gave a diagram of the performance of Caledonian engine No. 123. This engine took the West Coast racing train from Carlisle to Edinburgh, 100¾ miles, in 102 minutes 33 seconds; an average speed of 58·9 miles per hour. I am now able to name another remarkable achievement by a Caledonian engine, and this run was accomplished not on a special occasion, such as the race to Edinburgh, but in ordinary everyday work. For some time past the West Coast Scotch express, which leaves Aberdeen at 6.50 a.m., has been timed to run from Symington to Carlisle—a distance of 66 miles 69 chains—in 74 minutes, or an average speed of 54·1 miles per hour. On the day in question this run was accomplished in exactly 66 minutes = 60·7 miles per hour. The train was made up as follows:—4 W.C.J.S. eight-wheel bogies, 77 tons; 3 six-wheelers, 45 tons; 1 four-wheeler, 12 tons; engine and tender, 80 tons; total, 214 tons. The engine was one of the latest type in use on the Caledonian, having cylinders 19in. by 26in. Driving wheels 6ft. 6in. four-coupled.

The gradient profile—which for convenience is placed beneath the speed diagram—shows graphically the features of the road. At first sight it would appear to be mostly downhill; but as a matter of fact 38¾ miles are downhill, 4½ are level, and the remaining 23½ uphill. Many of our main lines are much more favourable to fast running than the one in question. The East Coast route so far as Newcastle is considerably less hilly; or the Great Western main line from Swindon to London; so that it cannot be said the route was especially cut out for such work. One or two points of particular interest may be referred to.

The most extraordinary feature in the run is the fact that the maximum speed only reached seventy-two miles an hour. Here was a fine stretch of fourteen miles solid downhill, which includes six miles of 1 in 75; the engine was one of a most powerful type, and the weight of train certainly not excessive; yet withal this run, which gave an average speed of over sixty miles an hour, included nothing higher than the very moderate figure of seventy-two miles an hour. I would emphasise this fact very strongly, because it shows that if the weight of trains be only kept within reasonable limits, the average speed of our best trains might well be timed considerably higher than at present. Further, those timid people who, during the Scotch race, cautiously travelled by the sober-minded Midland—where, needless to say, seventy-two miles an hour is by no means the limit—may well take comfort from the fact, and learn that with modern engines excessive speed along the banks is quite an unnecessary feature. Here also, I think, will be found an answer to those people who denounce the ponderous locomotives of the day as incapable of giving any better results than their predecessors. An older class of engine, having cylinders 17in. diameter and 135 steam pressure, and weighing about 35 tons, would most certainly have been incapable of achieving such a high average speed. It may be also interesting to estimate what would have been the gain in time had a really high speed been maintained down the banks. From post 46 to 38, eight miles were covered in 6 minutes 53 seconds = 69·5 miles per hour. Had this piece been run at, say, 80 miles an hour, it would have required exactly 6 minutes to cover the 8 miles, a saving of but 53 seconds. Again, post 12 to post 7 might have been run at 80 miles an hour, and a further 40 seconds would have been saved; making a total difference on the run of 1 minute 33 seconds. A few of the best pieces may be detailed:—

| | | | | | |
|---|---|---|---|---|---|
| Mile post | 61 to 1 | = 60 miles in | 57 minutes | 18 seconds | = 62·8 M.P.H. |
| ,, ,, | 48 to 2 | = 46 ,, ,, | 42 ,, | 5 ,, | = 65·5 ,, |
| ,, ,, | 46 to 39 | = 7 ,, ,, | 6 ,, | 0 ,, | = 70 ,, |
| (Uphill) | 61 to 50 | = 11 ,, ,, | 11 ,, | 55 ,, | = 55 4 ,, |
| (Uphill) | 26 to 24 | = 2 ,, ,, | 2 ,, | 0 ,, | = 60 ,, |

Permanent Way.

London, November 19th.

### METALLIC PISTON-ROD PACKING.

Sir,—Our attention has been called to the letter upon the above subject which appeared in your issue of November 9th, and as makers of metallic piston-rod packings, we may perhaps be permitted to say a few words in reply.

The term "metallic packing" is about as comprehensive as a Socialist's programme. Every device for filling the stuffing-box with some arrangement consisting partly or wholly of metal is dignified with the name of "metallic packing," and the number of such devices patented since Edward Cartwright led the way in 1797 would astonish those not conversant with the facts. Many of these productions should be dubbed "semi-metallic packings," for they consist simply of the old fibrous substances--hemp, asbestos, &c.—with perhaps a metal core or binding. As the effect of these upon the rods will be very similar to that of ordinary "soft" packing, we presume your correspondent requires no information in regard to them.

Packings which are purely metallic may be divided into two classes, viz., "rigid" packings and "self-adjusting" or "floating" packings, which terms denote the general principles of design. The number of rigid packings is enormous, and it is astonishing and amusing with what steady persistency inventors continue to "protect" the ideas which occurred to those first in the field nearly a century ago.

The number of successful self-adjusting or floating packings, can almost be reckoned on the fingers. To this class belong the packings manufactured by us, and having, in conjunction with the parent company in the U.S.A., fitted nearly 60,000 on all types of engines and in all parts of the world, we can speak "from experience" without entering into details of construction. We may say that our packing is so designed that the rod comes in contact only with blocks or rings of the finest anti-friction metal, such parts also being arranged to "float" with the rod and so prevent any binding. Now this anti-friction metal, so far from having any corrosive or injurious effect upon the rod, acts in quite a different way. The surface of the rod is in a manner "tinned," and so presents a beautifully smooth and bright surface, equally pleasing to the engineer and the packing maker. The packings cannot of themselves injure the rod.

Even with metallic packing the rods do sometimes show marks of some corrosive agency, but these can readily be accounted for when the surrounding circumstances are inquired into. Bad lubricant and bad water are the two principal delinquents, but of course their failings should not be put down to the account of the packing. We have seen some sad instances of stuffing-boxes eaten away by tallow, and we have a vivid recollection of one "engine tenter" who regularly used a compound of tallow and emery to "polish the rod."

Metallic packings are the piston-rod packings of the future. We have witnessed the gradual extinction of the prejudice which existed against devices of this kind, and we take some credit for having, by our success, assisted in the process. Soft packing was long ago exiled from the piston head, and with increasing temperatures and pressures it ought soon to be exiled from the stuffing-box, and replaced by metallic packings of the automatic self-adjusting type.

In your issue of the 9th inst., when describing the engines of the Union Steamship Company's mail steamship Norman, you state that the high-pressure rods are packed with the "American" metallic packing.

As the makers of the packings referred to, we desire to make a statement which may possibly correct a misapprehension. This company consists entirely of English shareholders, and the packings are all made at Bradford, Yorks, by local labour. The parent company, of Philadelphia, though still maintaining friendly relations, has been for many years an entirely separate concern. Hence you will see that practically the only American connection of the company is the name.

We would particularly like this to be known in view of the fact that at the present time we have orders for a large number of packings to be fitted to various vessels of the British Navy and to stationary and locomotive engines under the War Department and Colonial Governments. Englishmen naturally think that articles for Government use should bear no other legend than "Made in England."

W. M. Kermode, Secretary.

The United States Metallic Packing Company,
Bradford, November 20th.

Sir,—In reply to "Gland's" inquiry in your issue of 9th inst., we beg to say that a purely metallic packing, such as the "Tripp," for example, does not in any way corrode the rod, but it is quite possible that a semi-metallic packing, *i.e.*, one made partly of metal and asbestos, would have that effect, and experience has taught us that there is no middle path between a fibrous and metallic packing, a combination of the two never leading to satisfactory results.

Green and Boulding.

London, November 17th.

### BICYCLE MECHANICAL ENGINEERING.

Sir,—Your remarks about the Boudard gear appear to be borne out in practice, judging by the results of the races held recently by the Boudard and Whitworth companies between Boudard and plain-geared machines.

But this subject of bicycle mechanical engineering reminds one of the great want in the trade, namely, the want of standard screw threads for bicycles. It is surprising in these days, when standards and interchangeability are receiving so much attention in nearly all branches of mechanical engineering, that this important subject should have been neglected by the cycle trade.

It is no common thing in a cycle repairing shop to make special taps for tapping one cone or nut, the only alternative being to make a complete new spindle or what-not.

Cannot some of the large cycle firms take up this subject? We have standard gas and hydraulic threads, and there is a talk about standard threads for watches, and surely, now that the cycle trade has reached its present proportions, it is time that some attention was given to this important matter.

C. K. Dumas.

New Swindon, November 19th.

### LABOUR AND LUXURIES.

Sir,—It appears that the head and front of my offending has lain in the assertion that political economy has nothing to do with ethics. Perhaps the following quotation from an address delivered by Lord Farrer on the 20th instant, before the members of the Royal Statistical Society, in Jermyn-street, will serve to convince "W. A. S. B.," and "R. J. B.," that I have not spoken without warrant. Lord Farrer said: "That political economy had been taken to be more than it was or claimed to be. At any rate, there had been a revolt against it. It seemed to him that, whatever might be said of sociology or social science, and however strong might be the links by which that science connected ethics and economics, yet, in the present state of our knowledge, ethics and economics were on a different plane, and could not conflict, because they never met. Ethics was a science of art and duty which taught men what they ought to do or to aim at. Economic science had nothing to do with duty, was not an art, nor was it a code or system of laws. It was the branch of human knowledge which treated of the manner in which material wealth was produced and distributed; it endeavoured to ascertain the laws and conditions under which production and distribution took place, and pointed out that a certain course of action would have such and such effects on production and distribution. It was within the province of economics to tell us that families and nations who were weak and lazy were likely to starve. It was for ethics to say that such starvation would serve them right. It was for political economy to tell us that good work was not to be expected without good wages. It was for ethics to say that it was the duty of the employer to give adequate remuneration to those in his employ. Ethics appealed to man's conscience, emotions, and affections, while the business of economic science was purely intellectual, and taught what would be the probable result on material wealth of any given set of external conditions, or of any particular course of human action." Bearing in mind that these and kindred statements were made before leading political economists, and that they were received with acclamation, I venture to hope that they will have due weight with your correspondents, not one of whom has advanced a single statement of fact as yet to controvert my propositions.

Y. X.

November 21st.

Sir,—By a strange chance the gold actually imported into England in the last four completed years amounted almost exactly to the sum which "Y. X." invited us to suppose added to the gold in this country. It is, therefore, open to us to examine the reality of what has happened instead of indulging in hypothesis piled upon hypothesis. The greater part, of course, was re-exported, but the enormous sum of £26,000,000 on balance was added to our stock, an addition by far greater than any I can find record of in a similar previous period, amounting, it may be, to 20 per cent. of our gold currency. Unhappily no such prosperity has come with it as should have on "Y. X.'s" theory, so I am not yet persuaded to revert to the almost forgotten opinions of the mercantilists, which were exploded by Adam Smith.

While on the subject of gold, I wonder if "X. X.," who eighteen months ago was perplexed at the temporary excess of imports into the United States, and who "knew they could not pay for it in specie," has observed how the year's figures worked out, and how by July, 1893, they had paid away specie to the tune of 105,000,000, dols., or 70,000,000 dols. more than the excess of merchandise imported in the twelve months?

W. A. S. B.

November 20th.

## LAUNCHES AND TRIAL TRIPS.

On the 15th inst. the s.s. Tokomaru, built by Messrs. C. S. Swan and Hunter, Wallsend, and purchased by Messrs. the Shaw, Savill, and Albion Company, London, for their New Zealand trade, and which has received extensive additions, and has been fitted with insulated holds by Messrs. C. S. Swan and Hunter for the New Zealand frozen meat trade, to carry about 100,000 frozen sheep, left the Tyne for her trial trip and afterwards proceeded to London, the trial trip having been satisfactory in every respect. The dimensions of the Tokomaru are; Length over all 440ft., breadth 53ft., and depth moulded 34ft., and her deadweight capacity is about 9000 tons. The main engines, built by Messrs. the Wallsend Slipway and Engineering Company, are 31in., 50in., 80in. diameter by 54in. stroke, with three large double-ended boilers, 160 lb. working pressure, fitted with Serve tubes. The refrigerating machinery has been supplied by the Haslam Foundry and Engineering Company, Derby.

On the 15th inst. was successfully launched from the East Yard of Messrs. C. S. Swan and Hunter, shipbuilders, Wallsend, a finely modelled steel screw steamer of the following dimensions:—Length over all, 445ft.; breadth, 49ft.; depth moulded, 32ft. 10in. The vessel, which has been built to the order of Messrs. the Shaw, Savill, and Albion Company, London, has been specially constructed for the Colonial frozen meat trade to the highest class at Lloyd's, under special survey, and contains insulated holds capable of carrying about 100,000 frozen sheep. She is built of the three-deck type, with full poop, bridge house 250ft. long, and a long topgallant forecastle, with cellular double bottom throughout, and she has six water-tight bulkheads. The deck machinery includes ten powerful steam winches, with derricks on each side of the ship on steel derrick posts. The engines have been built by the Central Marine Engine Works, West Hartlepool, the sizes of the cylinders being 30in., 47½in., and 80in. by 48in. stroke. The boilers will be worked with forced draught on Howden's principle, and the refrigerating machinery has been supplied by the Haslam Foundry and Engineering Company. The vessel and machinery have been superintended during construction by Captain McKirdy, marine superintendent, and Mr. C. T. Young, superintending engineer, and Captain Scotland, of the Shaw, Savill, and Albion, and was named the Aotea by Miss Scotland, daughter of Captain Scotland.

On Thursday, November 15th, Messrs. Furness, Whitby, and Company launched from their shipbuilding works at Hartlepool a large steel screw steamer, built to the order of Messrs. Lunn and Maccoy, Newcastle-on-Tyne. The vessel is a substantial type of a modern cargo boat, measuring over 320ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at Lloyd's. She is an exact duplicate of the s.s. Birdoswald, built by Messrs. Furness, Whitby, and Company for the same owners, and which has given such excellent results. Every care has been taken in designing this ship to construct her as strong as possible for the heavy deadweight trade. The vessel is built on the web frame system, with cellular double bottom all fore and aft, and subdivided at intervals, the after peak being also available as a tank. The main and fore holds are divided by iron water-tight bulkheads efficiently stiffened by an iron longitudinal division. The greater portion of the shell plating is in 24ft. lengths, which is efficiently backed up by strong sectional framing to the top of vessel all fore and aft, the topside plating being extra thick to withstand the heavy Atlantic trade. The bottom plating is also thicker in way of the ballast tanks to allow for the vessel lying aground whilst loading. The whole of the weather decks, tank tops, floor plates, &c., are also of extra thickness, and the hatchways are of extra size to take in the bulkiest cargo; large winches to hatches, patent steam steering gear amidships, with hand gear aft, steam windlass, large donkey boiler, and patent stockless anchors. The vessel will be rigged as a pole masted schooner, and to make her available for bridges and canal work, the topmasts are telescopic. The engines and boilers have been constructed by Messrs. T. Richardson and Sons, Hartlepool, and are of massive design, with every provision for economical working. The ship and engines have been constructed under the supervision of Mr. Maccoy. On leaving the ways the vessel was named Ailsawald by Miss Daisy Maccoy.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The iron trade shows no decline on the week.

In further reference to the position of the railway carriage and wagon building trade, Brown, Marshalls, and Co., inform me that they have in hand an order for ironwork and fittings for 105 carriages for the Assam-Bengal Railway Company for shipment to India. They have also secured a contract for thirty-four large bogie carriages for the London, Brighton, and South Coast Railway. They lately shared an order for fifty tramcars for the Glasgow Corporation with their neighbours, the Metropolitan Carriage Company. Brown, Marshalls, and Co. are also just now shipping two trains of first-class corridor carriages for the Egyptian Government railways. These trains consist of five carriages, each carriage having four compartments, and communicating with lavatories, &c. They are intended for the expresses running between Cairo, Alexandria, and Ismailia.

A question of interest to the engineering and iron and steel trades of this district, where the road transit of heavy loads has frequently to be undertaken, is just now before the Board of Trade. I refer to the application of the Great Western Railway Company to that Department for their approval of bye-laws relating to the railway company's bridges. The railway wishes to limit the heavy traffic to loads of five tons. The Birmingham Chamber of Commerce—at the instance of Messrs. Danks, of Smethwick, the well-known boiler and bridge making firm—have memorialised the Board of Trade to raise the limit to eight tons. The lower figure would seriously hamper the engineering trades of this neighbourhood.

Much satisfaction is expressed hereabouts with regard to the reduction of canal tolls on coals, secured by the Birmingham Canal Order Confirmation Act, 1894, which has recently received the Royal Assent. This Act, which was promoted by the Birmingham Coal Merchants' and Consumers' Association, shows a substantial reduction of the tolls upon coal brought into Birmingham from the Dudley and Cannock Chase districts. The toll into Bordesley and Upper Birmingham has been reduced from 1s. 3d. a ton to 9½d., and into Perry Barr and Aston from 1s. to 9d. These rates compare with from 3d. to 6d. per ton in the Winson Green and Smethwick district, and will be a considerable relief to manufacturers and other large consumers. It is estimated that the reduced tolls will benefit consumers in Birmingham to the extent of nearly £50,000 a year, and the Corporation will itself derive advantage of the value of some thousands of pounds annually.

Electrical engineers will be interested to note that new electric machinery and plant is likely soon to be wanted upon a portion of the system of the South Staffordshire Tramways Company. For some time the West Bromwich Corporation have been urging the company to adopt some alternative method upon its lines running from Darlaston to Handsworth and from Dudley to Handsworth. The licence for the use of steam expired on the 1st inst. The Corporation have, however, consented to the licence being extended until January next, the company in the meantime to make some definite arrangement. The Corporation favour cable traction, so that cars may run right through to Birmingham without changing at Handsworth as at present, but the initial expense would be heavy. The West Bromwich tradesmen object to the overhead electric system on account of the poles on the sides of the footpaths. The manager of the company—Mr. Dickenson—has, however, invented a pole upon which the present-street lamps could be fixed, and which could support the electric wires at the same time. The tramway company leans towards electricity, and points to its successful working upon its other lines.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The position throughout the engineering, iron, and coal trades of this district remains without material change or improvement. Here and there one comes across a rather more hopeful tone amongst engineers, but this would seem to be based rather on more or less vague anticipations as to the future than upon any really definite prospects of present improvement. The iron trade in all departments continues extremely quiet, but there is one feature in the present position, the excessive lowness of stocks, either in the hands of consumers or makers, or in the public stores, that should not be lost sight of in estimating possible eventualities in the future, as the slightest indication of general reviving activity would almost to a certainty very rapidly force up prices. The condition in the coal trade continues about as unsatisfactory as it could possibly be, and very gloomy anticipations as to the future prevail in many quarters.

A depressed tone continues throughout the Manchester iron market, and the Change Meeting on Tuesday was practically a repetition of the extremely quiet markets for the last month or so. In pig iron it is quite exceptional where business of any weight is being put through, users hanging back as long as possible before placing out further orders, and when they do buy it is only at some concession upon previous quoted rates. Lancashire makers still nominally quote on the basis of 39s. for forge, up to 42s. for foundry, less 2½, at the works, but these figures are altogether out of competition with district brands, and it is only where local makers have specially favourable rates of carriage that they are booking occasional orders with regular customers. With regard to district brands, forge Lincolnshire is becoming somewhat of a drug upon the market, owing partly to the very restricted requirements of consumers, and partly to the irregular working of some of the furnaces, which are just now turning out a considerably larger proportion of forge as compared with foundry numbers, and to get rid of surplus supplies of forge very low prices are occasionally quoted. Business has been done during the last few days at about 38s. net cash for forge Lincolnshire, delivered equal to Manchester, but there are sellers at under even this low figure. Foundry qualities are fairly steady at recent quotations, Lincolnshire averaging 39s. 6d. to 40s., and Derbyshire ranging according to brand from about 43s. to 45s. net cash, delivered here. Outside brands are about as last quoted, but it is exceptional where more than 44s. 4d. net cash is being got for good foundry Middlesbrough, delivered Manchester. For Scotch iron quotations average about 47s. 6d. for Eglinton, 48s. 6d. for Glengarnock, and 50s. for Gartsherrie, net prompt cash, delivered Lancashire ports.

Finished iron makers still report new business coming forward very slowly, and forges for the most part scarcely kept on more than about two-thirds their normal production. Delivered Manchester district, Lancashire bars average about £5 6s. 3d. to £5 7s. 6d., and Staffordshire £5 7s. 6d. to £5 10s., but as low as £5 5s. f.o.b. Liverpool has been taken by Lancashire makers on shipping orders. Lancashire and Staffordshire sheets remain at about £7 to £7 5s., and Lancashire hoops £5 17s. 6d. for random to £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Nut and bolt makers also report trade in a very unsatisfactory condition, with few orders of any moment stirring, but prices, which seem to have got to about their lowest point, remain stationary.

The steel trade continues generally in a very lifeless condition, with prices about as last quoted; good ordinary foundry hematites remain at about 52s. 6d., less 2½, with low-class billets obtainable at about £3 17s. 6d. to £4, and best billets quoted £4 7s. 6d. to £4 10s., net cash; steel bars average £6 to £6 2s. 6d., according to quality, and steel boiler plates £6 2s. 6d. to £6 5s. per ton, delivered in this district.

In the metal market business drags on from hand to mouth. There was a general expectation that some reduction in list rates for manufactured goods would be made during the past week; but so far they remain without alteration.

The condition of the engineering industries remains very much as I have reported for some time past. Stationary engine builders, as a rule, are fairly off for work, and some of the machinists are tolerably busy, whilst the leading machine tool makers are also tolerably well off for orders; but it is exceptional where establishments have any work far ahead. Generally the most that can be said is that they are just kept going, with not a few establishments extremely slack. This is especially the case with locomotive builders, whilst boilermakers report a considerable falling off in this branch of trade as compared with a few months back.

I hear of some friction which has arisen here and there between masters and their workmen in this district on the overtime question, with regard to which the men are endeavouring to impose further restrictions, whilst there is also an attempt to prevent a workman attending to more than one tool at the same time. So far, the action which the men have taken upon these matters has not rendered necessary any combined general movement on the part of the masters, but it is being strenuously resisted by individual employers, where attempts are being made to introduce these restrictions.

Messrs. Galloways Limited, of Knott Mill, are just now very busy on several large special orders, one of these including exceptionally powerful rolling-mill engines for a steel works in the United States, to which I may possibly make further reference later on, as a noticeable feature is that they are being completed in the space of not more than three or four months.

Messrs. Hulme and Lund, Pomona Works, Manchester, have recently completed a pair of horizontal pumping engines of the girder type, specially designed for colliery work, which contain several features of interest. The cylinders are 34in., the stroke being 30in., and the engines are to work in combination with quadruple-acting ram pumps, with 12in. by 30in. stroke, and having a capacity for raising 60,000 gallons per hour 480ft. One special point in these engines is that the connection with the pumps, which is by long distance pieces and coupling boxes, so that the pump rod does not enter the steam cylinders, can be readily removed to allow of a thorough examination of the piston, all that is necessary being to take out the nuts and bolts in the distance pieces, and remove the coupling-boxes, when the connection can be easily taken out without disturbing the engines or the pumps. Amongst other work, Messrs. Hulme and Lund have in hand the construction of a pair of horizontal pumping engines to force 900ft. high with 20in. cylinders, the pumps working behind, this being the third pair the firm have had on order from the same firm, who require them for colliery purposes, and they have recently sent out a set of 10in. quadruple vacuum pumps of special design, for cop-drying in cotton mills.

Extreme depression continues to be reported throughout the coal trade of this district, with pits only in exceptional cases working more than four days per week, and prices showing a persistent weakening tendency. The better qualities of round coal still meet with only a very poor demand for house-fire purposes, and although quoted list rates are unchanged, specially low figures are frequently quoted to clear away anything like quantities. The average current prices scarcely exceed 10s. 6d. to 11s. for best Wigan Arley, 9s. 6d. to 10s. for Pemberton four-feet and seconds Arley, with common house coals obtainable at from 7s. up to 8s. per ton. As regards the lower qualities for iron-making, steam, and general manufacturing purposes the position is equally unsatisfactory, owing to the restricted requirements of the principal coal-using industries. Supplies of steam and forge coal are largely in excess of the demand and prices excessively low, 6s. 6d. to 7s. being about the average figures at the pit mouth.

As an illustration of the exceptionally depressed condition of the coal trades not only in this, but in other districts, I may mention that a contract has just been settled for the supply of 60,000 tons of gas coal for Belfast. The Lancashire coalowners have usually had the supply, at any rate, of a considerable portion of this contract, and their quotations were about 13s. per ton for delivery at Belfast. The contract has, however, been secured by a Yorkshire firm at, it may be presumed, under even 13s. per ton, and a further not very pleasing feature for Lancashire owners is that the coal is being shipped *viâ* the Manchester Ship Canal at Partington, whilst the price at which the contract has been secured will probably scarcely leave more than 6s. per ton at the pit mouth in Yorkshire.

Engine classes of fuel continue a general drug upon the market, with sellers at all sorts of prices, where contracts can be made or orders of any weight secured. Good ordinary Lancashire slack has been sold as low as 3s. to 3s. 6d., with best qualities scarcely averaging more than 4s. 6d. to 5s. per ton at the pit mouth, and slack from other districts continues to come in here at prices which do not leave more than about 1s. 6d. per ton at the pit mouth.

The shipping trade continues very quiet, with low prices ruling, ordinary steam coal being obtainable at from 8s. to 8s. 6d., whilst better qualities are quoted at 8s. 9d. to 9s. per ton, delivered at the Garston Docks or the High Level, Liverpool.

*Barrow.*—The hematite market is still very much depressed, and orders are coming to hand slowly. On home account there is really less doing, and business with foreign countries is less than it has been for years. Prices are easy at 43s. 4½d. cash sellers, buyers 1d. less. Makers ask 44s. to 45s. for Nos. 1, 2, and 3, Bessemer iron. Stocks have again increased this week by 1500 tons, and now represent 166,227 tons, being an increase of 71,604 tons since the beginning of the year. One furnace has been blown out this week, and there are now only thirty-two in blast, compared with thirty-three at the same time last year. There are seventy-five furnaces in the district.

Iron ore is very quiet, and even local sales are on the wane. Prices are, however, steady at late rates, 8s. 6d. for ordinary and 13s. 6d. for best descriptions, net at mines.

Steel makers are short of orders, generally speaking. The demand for rails keeps very quiet, and makers have little in hand. The mills are worked only at intervals. The plate mills are busy on the new orders recently booked, and other work is expected. Tin-plate bars are a quiet trade. There is practically nothing doing in blooms, billets, slabs, hoops, or wire rods, but heavy steel castings are still in demand.

Shipbuilders and engineers are very busily employed and are likely to remain so. The Naval Construction and Armaments Company last week booked an order for a duplicate of the sand pump dredger Brancker, built by it for the Mersey Bar. The Brancker has proved such a satisfactory ship, and has done so much to improve the approaches to the Mersey, that the Dock and Harbour Board determined to have a duplicate ship, and this will be built at Barrow.

The coal and coke trades are very quiet, and the consumption is less. Prices, however, are very steady.

Shipping shows a slight improvement. The exports from West Coast ports during last week represented 11,950 tons of pig iron, and 6405 tons of steel. In the corresponding week of last year 2355 tons of pig iron and 4752 tons of steel were shipped, showing an increase of 9595 tons of pig iron and 1653 tons of steel. The aggregate shipments to date this year amount to 315,435 tons of pig iron and 353,251 tons of steel, comparing with 244,844 tons of pig iron and 421,382 tons of steel in the corresponding period of last year, an increase of 70,591 tons of pig iron and a decrease of 68,131 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

TRADE is again rather weaker in coal. The continued mild weather has kept down the demand for household sorts, which would soon be exceedingly active if a sharp frost were to set in for a few days. Coalowners report that there is literally no business doing. The coalfields in this district are nevertheless being energetically opened out, particularly in the direction tending towards Doncaster, and there is every probability that the present generation will live to see the headquarters of the South Yorkshire coal trade transferred to the Doncaster district. The winter quotations, with the advances usually imposed in October and November, have not been maintained. Silkstones are now at 9s. 6d. to 11s. per ton; Barnsley House, 8s. 3d. to 9s. 3d. per ton; second qualities from 7s. 9d. per ton. To the Humber ports a large weight of steam coal is sent, but as the output of this class of fuel is continually increasing the prices are weaker, and are not likely, at this period of the season, to advance. Barnsley hards are now supplied at 7s. 6d. to 8s. 3d. per ton, other qualities from 7s. 6d. Gas coal is being briskly delivered on account of contracts, but sales made in the open market are unusually light, the prices obtained in the latter instances being from 7s. to 8s. per ton. Manufacturing fuel is in diminishing request, with the result that stocks accumulate and values do not vary much from 3s. 6d. to 5s. 6d. per ton. For coke, 9s. to 11s. per ton is being obtained; business quiet.

The directors of the Roundwood Colliery Company have just issued their fifth annual report, which shows a loss on the year's working of £235 0s. 5d. Deducting the balance of £10 9s., brought forward from last year, the balance to carry forward to this year is £222 11s. 5d.

In the iron market there is no improvement to be noted. The low price of material prevails all round. The fall in hematites of 1s. per ton, which has been already noted, still continues. West Coast brands are now quoted at 52s.; North-east Coast brands at 50s. per ton, delivered in Sheffield. Lincolnshire iron, which is very depressed, stands at 38s.; Bessemer billets, £5 7s. 6d.; bar rods, £5 5s. per ton at manufacturers' works. A little improvement is reported in the demand for the shipbuilding yards. Freights are getting somewhat firmer, and if the stiffening tendency continues, there is certain to be some new ships given out. Marine specialities, such as boiler flues, &c., are again being actively called for by shipbuilders.

In the heavy steel departments there is a satisfactory amount of work doing, all the hammers and presses in the great establishments of Attercliffe and Brightside being now fully employed.

Orders for stores have been placed well during the last fortnight by several of our large railway companies. These are usually followed by more important contracts for railway material. As yet Birmingham has alone benefited by the development that is going on in India; but if it continues, as is expected, the Sheffield firms are certain to reap the advantage before long. The makers of wheels, tires, axles, springs, and buffers are doing fair work, with every expectation of increased pressure later on.

As the season progresses the trade in specialities for Christmas and the New Year gets increasingly brisker. All our leading establishments in the lighter staple trades are now working full time, and many of them extra time. The demand is mainly for the novelties which are most popular for presentations and friendly offerings. The wet season has told somewhat against business at the seaside and other watering-places, but this may be compensated for, in some extent, by the open winter, which, if continued, will encourage landlords of hotels and hydropathic institutions to replenish their stocks. A rather better order has been received from Ireland, the unfailing index of trade there being that while political questions, particularly *the* political question, which disturbs the country are to the front business gets weak, and while politics are little heard of it revives. The Scotch trade has been fairly good through the season, particularly in the West Coast and central districts.

A season trade of exceptional importance now is the manufacture of presentation cups, shields, trophies, vases, and all the other various forms in which prizes and competitions in cricket, football, golf, tennis, &c., are required. The steady drift of the silver trade to the Sheffield district has caused this department to receive exceptional attention of late, and many most artistic designs have been produced for these purposes. A considerable number of artists are now employed on these specialities, and the extraordinary popularity of football and golf has added quite an important branch to the silver, plating, and cutlery trades, chiefly to the former.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

MANUFACTURERS generally in this district speak very despondently about business. They are getting few orders to take the places of those they complete. and have no reason to look for any brisker state of affairs—at least, until the winter is over. They have, as a rule, reduced their prices in most departments until they yield no profits, and in many cases they do not cover cost of production; yet consumers are even loth to pay them, and seem to think that they will be still lower. They have, therefore, not enough confidence to buy for forward delivery, and confine their purchases to small lots for prompt delivery. It must be confessed that the tendency of prices is rather downward than upward for nearly all manufactured iron and steel products, and the pressure to sell is considerable, because producers have difficulty in finding anything like regular work for their men, and at most places a portion of the plant is laid off altogether.

Some of the steel manufacturers do not realise any profit on the steel they produce, and state that all the profit they do get is from the slag which they produce when making basic steel. This they can readily dispose of to those who crush it up and sell it for manurial purposes. A large quantity is shipped from this district to Germany, where it is used as a manure by the growers of beetroot. This utilisation of what was formerly a waste product enables the steel manufacturers to keep their establishments going without loss, where otherwise they would not be able to continue operations. This year over 58,000 tons of basic slag manure have been shipped over sea from the Tees, and the quantity consumed at home is increasing rapidly, as its peculiarities and suitability for various lands are becoming better understood.

Heavy steel rails are quoted as low as £3 12s. 6d. net per ton at works; but no very important orders are offered, and there is keen competition when quotations are asked. Ship plates can be bought at £4 15s., less 2½ f.o.t., and the buyer can have his choice whether he will have them of iron or steel, though the producer would prefer him to take the latter, because they cost less than the iron to manufacture. Some little business is said to have been done as low as £4 12s. 6d.. less 2½ f.o.t.; but even that does not meet the views of some consumers. Iron and steel angles are also about the same figure—£4 12s. 6d., less 2½ f.o.t.—and relatively a better price is obtained for them than for plates, as the cost of production is less; but the competition in this department is not so keen as it is in plates. Common iron bars continue at £4 17s. 6d., less 2½ f.o.t.

The exports of pig iron this month are unexpectedly heavy, but that does not in any way add to the strength of the market; indeed, it has failed to prevent a further fall in the price of No. 3. Usually in November the exports are greatly curtailed, as nominally the navigation season proper is over, but occasionally when the weather is favourable, as it is this month, large quantities are shipped, more especially after October has been a bad period for delivering iron abroad, and in one November upwards of 100,000 tons of pig iron were shipped from the Tees, almost the largest quantity ever reported in any month. This month's shipments up to Wednesday night from the Tees were 59,418 tons, as compared with 54,735 tons last month, and 46,021 tons in November last year to 21st. It is probable that under these circumstances the stocks, which have in every month since June shown an increase, will this month exhibit a decrease, just reversing what ought to be the experience. In Connal's warrant stores on Wednesday, 89,078 tons of Cleveland pig iron were held, or 447 tons increase this month.

Though such good pig iron shipments have been recorded, and they are chiefly of No. 3 Cleveland G.M.B., and though this quality is undoubtedly very scarce, yet lower prices have this week been accepted—35s. 7½d. per ton for prompt f.o.b. delivery, and 35s. 9d. for the first quarter of next year, some makers taking this as they think it unlikely that there will be a rise before the spring, seeing that the dullest period of the year will have to be passed through, and the prospects of the consuming industries are not encouraging. Cleveland warrants are quoted 35s. 5d. cash, but business in them, as in all other warrants, is lifeless, because speculators have not confidence enough to risk their money in them, and place it where it is safe, though bringing in next to no interest. No. 4 Cleveland pig iron is sold at 34s. 9d., and grey forge is readily got at 33s. 9d., and some business is reported at 33s. 7½d. Better prices will be secured for white iron if steel makers follow the example of Messrs. Dorman, Long, and Co.; at present very little white is made, and little is in stock, but if a demand for the quality arose, pig iron makers would specially burden some of their furnaces for it. The hematite pig iron trade is very unsatisfactory, as make continues in excess of consumption, and stocks increase, as they have been doing for some months, and yet no move is made to reduce the output. Producers complain of the low and unremunerative prices, but nothing more can be expected when there is an excess of iron turned out.

The situation for makers of hematite is not good, for while their selling price declines, their cost of production does not; in fact, foreign ore is dearer than it was last month, and most of the merchants are quoting 12s. 1½d. per ton delivered Tees for good Rubio over next quarter. Very large quantities have recently been received; in fact, on Monday over 15,000 tons arrived. Coke is no cheaper, the combination of coke manufacturers providing against this, and they have no difficulty in maintaining their rates when no reduction in the consumption is made. Mixed numbers of East Coast hematite pig iron have been sold this week regularly at 42s. 9d. per ton.

Cleveland long had the reputation of producing the cheapest pig iron in the world. A short time ago Mr: Jeremiah Head, who was on a professional visit to the United States, informed the ironmasters of the North of England that in Alabama pig iron was being made at a cost several shillings below the figures reported in Cleveland. It was costing 23s. to 24s. per ton, and was sold at works at from 26s. to 27s. per ton, whereas the selling price of Cleveland No. 3 was 36s. The British ironmasters were not inclined to believe this statement, but it has been fully confirmed by one of the managers in the district referred to, who offers to deliver his No. 3 at Pensacola, f.o.b., at 30s., and his grey forge at 29s. per ton. Pensacola is the nearest port to Birmingham, Ala., but is 260 miles away. It is stated that the ore only costs 3s. per ton delivered, and requires no lime, while it contains 38 per cent. of metallic iron. The coke costs 7s. 6d. per ton at the furnaces, and labour is cheap. The cost of materials is thus considerably below what it is in Cleveland. Mr. Bowron, the manager referred to remarks that they are prepared so far as pig iron is concerned, and also steam coal, to compete with English producers at any points where they can obtain equally favourable rates of freight for the use of marine tonnage. This condition of affairs is not due either to the existence of Free Trade or to its near approach, but is due to the favourable natural conditions pointed out by Sir Lowthian Bell twenty years ago, and carefully examined into by Mr. Bowron's father and Mr. Thomas Whitwell. Mr. Bowron is a native of Stockton-on-Tees, and was connected with the iron trade there before he went to Alabama twenty years ago.

The death took place last Friday of Mr. Tnomas Siddell, one of the oldest employés of the Consett Iron Co. He was 78 years of age. From an ordinary workman he rose to be manager of the puddling department when puddling was in the height of its prosperity, and since he has been manager of a portion of the establishment known as the Tin Mill Works. Mr. Siddell was one of the representatives of the Consett Iron Co. on the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trades of the North of England, and Mr. W. Whitwell, the president of that organisation, as well as several oi the employer and operative representatives, attended the funeral.

The quantity of ore exported from the Gellivara iron ore mines in Sweden this year has amounted to 523,000 tons, against 259,826 tons in 1893, and 138,943 tons in 1892. This ore is sent to Germany, Belgium, and the North of England. It is shipped from Lulea, and the shipping season lasts from May to the end of October.

It has been mentioned several times in these columns that the commercial men of Sunderland were agitating for better railway station accommodation. It was in June of last year that a deputation from the Town Council waited upon the directors of the North-Eastern Railway Company. Since then the subject has been frequently under the consideration of the directors, but the difficulties which would have to be encountered in making any material alterations in the arrangements at the station have prevented a satisfactory scheme being devised. A special committee of the directors has now been appointed to give further consideration to the question. The West Hartlepool Railway station is to be enlarged, and arrangements made so that the through traffic can be worked on an independent cut line.

A new railway is proposed through the dales of West Yorkshire; it is practically a resuscitation of the scheme promoted nine or ten years ago in an amended form. The line is intended to form a junction with the Midland at Hellifield, and will pass through Kettlewell, Middleham, Caverham, Leyburn, Richmond to Darlington, where a junction will be formed with the North-Eastern Railway. Powers are to be sought to utilise the Bank Top station there.

The patternmakers' strike which has existed in the North of England since last May still continues, the men claiming 3s. 6d. per week advance in wages. A conference of masters and men was held at Newcastle on Monday, but nothing was definitely settled.

A marine, electrical, and engineering exhibition was on Tuesday opened at Sunderland by the Mayor, and is to remain open for two months. There are over 300 exhibitors. Part of the proceeds of the Exhibition will be given to the Sunderland Infirmary.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been comparatively steady. Whatever changes occurred has been rather in an easier direction. The amount of business done has been limited. Little speculative feeling exists in the market at present. Scotch warrants have sold from 42s. 6½d. to 42s. 5d. cash, the demand being comparatively poor. Cleveland iron is quiet, warrants being worth about 35s. 6d. cash. Hematites are dull at 43s. 4d. for Cumberland, and 42s. 3d. for Middlesbrough warrants.

A fair demand exists for the special brands of maker's iron. The cheaper qualities have about maintained their value, but the principal brands are 6d. per ton cheaper. G.M.B. f.o.b. at Glasgow, No. 1, is quoted 44s. per ton; No. 3, 42s. 6d.; Monkland, No. 1, 45s. 6d.; No. 3, 42s. 6d.; Carnbroe, No. 1, 47s.; No. 3, 44s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie and Calder, No. 1, 52s.; No. 3, 48s.; Summerlee, No. 1, 53s.; No. 3, 48s.; Coltness, No. 1, 55s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 52s.; No. 3, 48s.; Eglinton, No. 1, 48s.; No. 3, 45s. 6d.; Dalmellington at Ayr, No. 1, 48s.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 56s.; No. 3, 50s. 6d.

There are 46 furnaces producing ordinary and 20 hematite pig iron, the total of 66, comparing with 54 at this time last year. Two furnaces have been transformed from ordinary to hematite, the latter being in better demand for steel making purposes. The manufacture of basic iron is still suspended.

The shipments of pig iron from Scottish ports in the past week have been 7712 tons, compared with 5606 tons in the corresponding week of last year. There was sent to the United States 110 tons; South America, 245; India, 550; Australia, 580; Italy, 525; Germany, 320; Holland, 550; Belgium, 50; Spain, 66; China and Japan, 268; other countries, 685; the coastwise shipments being 3793 tons against 1166 tons in the same week of 1893. The foreign demand is small; but the season of the year is unfavourable for an expansion of the export business.

The finished iron and steel trades are without material alteration. Business in manufactured iron has been improving slowly, and the demand for steel is also on the increase, but prices in both cases are deemed unsatisfactory.

The shipbuilding trade is fairly employed. A number of fresh orders are reported, among these being two steamships of about 4500 tons each, to be built for a Spanish firm by Messrs. Charles Connel and Company, Whiteinch. The vessels will be fitted with triple-expansion engines, the order for which has been placed with Messrs. Dunsmuir and Jackson, Govan. Two swift steamers are also to be built for the Caledonian service on the Firth of Clyde, to be ready for next tourist season.

The exports of manufactured iron and steel from Glasgow in the past week embraced sewing machines worth £1183, locomotives £545, other machinery £31,750, steel goods £12,100, and general iron manufactures £24,360.

There is a rather easier feeling in the coal trade. The demand has now been fully overtaken by the output of the collieries, with the result that prices have been easing off. The coal shipments in the past week amounted 147,970 tons, compared with 151,397 in the preceding week. There was a large falling off at Grangemouth. The demand for the Baltic is now practically ceased for the season. A little more business is being done with Ireland. Household coals move off slowly for home consumption.

The miners' delegates are endeavouring to get up a fresh agitation in favour of an advance. At a conference in Glasgow a few days ago they adopted a resolution in support of 6d. per day advance, and deputations are now being sent to employers to make this demand. The men can have little hope of success, especially as prices are rather going back at present.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE weather has continued to tell adversely against the coal trade, for if a fine day or two is experienced, allowing tonnage to come in, and sidings relieved, it has been followed by gales that have again caused prices to droop. On the whole there is a firmer tone in prices of best steam coal than existed last week. Prices, which appeared to be settling down into 11s. for best, have gone up 3d. to 6d., and the latest quotations for this week are 11s. to 11s. 6d for best, with a slight improvement in all kinds. Thus, midweek, at Cardiff, seconds were quoted at 10s. 3d. to 10s. 6d., best Monmouthshire the same; best small, 5s. to 5s. 3d.

For best house coal prices are firm and demand improving. Cardiff prices this week are:—Best house, 10s. 9d. to 11s.; No. 3 Rhondda, 10s.; brush. 8s. 3d.; small, 6s. 6d.; No. 2 Rhondda, 8s. 3d.; through, 6s. 3d.; small, 4s. 3d. to 4s. 6d.

Similarly at Swansea and other ports, the weather has produced a great change in the prosperous condition of things. The total import and export trade of Swansea last week was only 39,851 tons, as compared with 42,104 tons the previous week, and 52,927 tons the corresponding week last year. A few items will show the falling-off. In coal, for instance, the export was limited to 21,651 tons; patent fuel, which has touched 10,000 tons and even more, 890 tons; and tin-plates and general goods, 6911 tons. The shipments of tin-plates alone were 47,382 boxes, while there was received from works nearly double—83,739 boxes.

Two good points may be noted in Swansea Harbour trade. Thus 5000 tons of Spanish ore came in last week, and for this and next week seven sailing ships will go out with anthracite coal to San Francisco. Total tonnage, 12,825 tons.

Competitive works in the North of England and Scotland continue to send into Wales large quantities of pig iron. Middlesbrough, Barrow, and Millom, figure amongst the largest.

Patent fuel shares the fortunes of coal, and is only in moderate demand, 10s. 6d. to 11s. Cardiff, and 10s. to 11s. Swansea. Coke prices remain the same Swansea and Cardiff, and not much improvement is expected until the iron and steel trades improve. Of this the signs are very faint. Quotations, Swansea Exchange, mid-week, are little altered from those of last week. Glasgow pig warrants are at 42s. 6½d.; Middlesbrough, No. 3, 35s. 6d. prompt. Welsh bars, £5 2s. 6d. Rails, heavy, from £3 15s.; light, from £4 7s. 6d. Sheet was £6 to £6 10s. Steel sheets, £6 5s. to £6 10s. Bessemer steel bars, £4 to £4 2s. 6d. Siemens, £4 to £4 2s. 6d., all delivered in district; cash less 2½. Rail prices 2s. 6d. easier at Cardiff.

Tin-plate remains in only moderate demand at last prices. Bessemer cokes are quoted at 10s. to 10s. 3d.; Siemens coke finish, 10s. 3d. to 10s. 6d.; ternes per double box, 28 by 20 c., 20s. to 24s.; best charcoal, 11s. 6d. to 12s. 6d., according to finish of brand; wasters, 6d. to 1s. less than primes; odd sizes, usual extras.

Copper and block tin are receding in price.

Pitwood commands, perhaps, the most notice of the week. In part owing to the stormy weather and the limited quantity on hand at Spanish and French ports, the great accumulations in Cardiff have been nearly cleared off, and for some days there was quite a timber famine, and prices advanced from 15s. to 22s. per ton. Midweek things are getting easier, and with the arrival of cargoes the late quotations of fifteen shillings will, I believe, be resumed.

It is much to be feared that a crisis of no ordinary magnitude is approaching in the tin-plate industry of Wales. So far action is disjointed, and if ominous news comes from one district tidings of better import reaches from another. Still, the fear is that as we near the end of the year, to the close of which amicable arrangement in a few quarters extend, the great body of the plate workmen may be brought into accord, and a wage conflict ensue, which, unless a great change takes place in the condition of things, can have but one ending, and that a disastrous one.

This week a conference of owners and men was arranged at Llanelly, and the attendance was a large one, but when it was announced by two leading representatives of the men that no reduction of wages would be allowed, the employers at once arose and left the meeting. The forecast is a gloomy one.

Abercarn Tin-plate Works will be brought to the hammer this week consequent upon the death of Mr. Whitehouse, J.P.

I see that the new form Siemens' steel ingot heating furnaces has been adopted by the Cwmpelin Tin-plate Company, which has two, and the Copper Miners' Tin-plate Company has two, and now the Albion Steel Company at Briton Ferry is building two on the same plan. In the Newport district I must also note that J. J. Cordes and Co., of Newport, and the firm of Tinn and Co., of Pontnewynydd, are building furnaces of this new type for heating and welding iron piles.

In the Cyfarthfa district the new industry, the brick-making, is assuming large proportions, and the coke ovens will soon, to all appearances, enable the able manager to meet the fullest demands, for I hope to announce, the requirements of a large bar trade. There is a steady make at present, and the circle of buyers appears to be widening.

I referred last week to the certainty of important Bills from Wales being brought forward for next session, and am now enabled to confirm it.

Rhymney will apply for powers to construct a railway from Ystrad Mynach Station to Gellygaer Common. Also for power to abandon the construction of railways authorised by the Rhymney Act of 1888. Parliament also will be asked to sanction the creation and issue, in substitution of the ordinary stock of the company, other stock of such nominal amounts as the company think fit or the Act may prescribe. A large majority of the shareholders, I learn, are in favour of the division of stock.

The Barry Company notify its intention to apply for powers to construct a line from Pontypridd, along the Taff Valley, and into the Rhymney Valley, where it is proposed to form a junction with the Rhymney Railway near Bargoed Station. A branch will connect the line with the Brecon and Merthyr Railway, near Gilfach. In the event of the Barry securing powers, it will give connection with the North-Western, Great Western, and Brecon and Merthyr systems. The same company also applies for power to make a short line from the existing Barry line up the Rhondda Valley as far as the Cymmer Colliery.

Notices have been issued by the Great Western, Taff Vale, Rhymney, and other railways, of opposition to the Bute Docks Bill. The present arrangement is that the railways in question are under obligation to convey traffic over the Bute lines to the staiths and sidings, for which it is stated they receive no payment. The Bill now being prepared by the opposition aims to secure relief from this by the payment for services, the same to be settled by arbitration.

The Vale of Glamorgan Railway Company will apply for powers to make certain deviations and to extend the time for compulsory purchase of land, &c.

The Rhondda and Swansey Bay will seek powers to construct certain short railways at Swansea, Neath, and Briton Ferry, &c. Altogether a busy time is forecast and a keen contest is almost assured.

I regret to announce the death of Mr. E. H. Watts, of Newport. He was a member of the firm of Watts, Ward, and Co., and one of the largest coal-exporting firms in the country, having branches at London, Cardiff, Newport, Newcastle-on-Tyne, Blyth, and several foreign stations. He was a member of the Newport County Council, and also a prominent figure in the social and intellectual life of Newport.

Pontypool is preparing to apply to the Board of Works for a provisional order to supply the electric light in the district.

The Cardiff electric lighting is now in operation, and extensions poration.

Rumours of a great colliery undertaking are rife in Cardiff, and are supposed to refer to the amalgamation of existing companies, but particulars are kept scrupulously private. A local authority, referring to the rumour, states that they do not refer to Locketts, which has been taken over by a syndicate at £200,000, or to the rumoured amalgamation of the Albion—Colfynydd—and the Universal, now being sunk at Aber, near Caerphilly, an adjoining coal property.

I shall refer next week to the Bute Dock Bill, which contains many interesting and important clauses. One clause is the enforcement of the use of the electric light upon all vessels coming in or going out, and in view of the periodic explosions on coal vessels, this is an excellent suggestion for legal enactment.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

IRON business is reported all round rather bad in this country. Only in exceptional cases are establishments at all busy, and this mainly upon work of a special character. A general holding back from placing out further orders has been noticeable in all branches, which is partly due to a prevalent expectation of a still further reduction in prices, and very little business has consequently been doing upon the week.

In Silesia a quiet or rather lifeless tone characterises the iron trade. The blast furnace works are on the whole poorly employed, and very little pig iron has been sold of late, so that an increase in stocks is reported from several parts. Demand for the different sorts of malleable iron is also but small. Buyers do not come forward with their orders until at the very last moment, and then only purchase what is actually required. Under these circumstances business in iron and steel cannot be otherwise than extremely unsatisfactory for both producers and consumers. Whether the proposed Silesian rolling mill convention will be formed remains to be seen; for the present the parties concerned have not come to an agreement. Prices are reported to have not altered, but are in fact anything but firm.

Austro-Hungarian iron business, though not particularly brisk, has, on the whole, been quite satisfactory, the different branches of the iron and steel trade remaining in sufficient employment. Pig iron is still scarce, and large lots come in from foreign markets. Manufactured iron shows a firm tendency, bars and plates being rather briskly called for, and even girders have been in somewhat better request, owing to a fair activity that is still to be perceived in the building line. The railway and engineering department is poorly employed generally. There is a good retail business doing in hardware, and an increase is noticeable against last year. Although the state of the iron industry in France is rather unsettled for the present, there is, nevertheless, a very confident tone prevailing among ironmasters in general. A good activity is noticeable at the works, but, as stocks are still rather large, an improvement in prices cannot, as yet, be ventured upon, and in a number of cases makers even had to go down a few francs, especially for bars and sectional iron. The proposed forming of a syndicate for plates has made no further progress, as some of the larger mill owners cannot make up their minds to join the convention.

Though a little more life is undoubtedly manifested in most branches of the Belgian iron trade generally, the improvement is progressing but slowly, and there are still some departments where orders are very scarce and activity insufficient. Prices have been tolerably well maintained in most instances, although, of course, makers are still in the habit of under quoting each other whereever a contract of some weight is offering. Finished iron makers, especially, have to submit to reductions pretty frequently. The price which Belgian works realised at a late tendering for rails was 119·90f. p.t. Import in pig iron to Belgium has this year been uncommonly brisk, Germany, Luxemburg, and North France having thrown large quantities of iron on the Belgian market. During the first nine months of the year import in pig iron was:—

| | 1894.<br>Kilos. | 1893.<br>Kilos. | 1892.<br>Kilos. |
|---|---|---|---|
| | 170,482,460 | 99,471,928 | 108,815,094 |
| From Germany | 32,328,921 | 26,175,634 | 28,329,815 |
| „ Luxemburg | 42,965,610 | 3,478,660 | 979 |
| „ France | 54,875,437 | 34,356,965 | 38,228,065 |

The aspect which the Rhenish-Westphalian iron industry continues to present is unfavourable in the extreme. As makers are not the least anxious to buy for forward delivery, and hold back with their orders as much as possible, the iron market is in a state of stagnation almost, the hand-to-mouth sort of business that is done being insufficient to keep the works in constant employment; while competition prevents a rising in quotations. In pig iron a fair amount of orders has been secured by the Siegerland blast furnace works, and pretty large lots are sent abroad. All sorts of malleable iron remain in very quiet demand, as home consumption is extremely limited, while there is next to no inquiry experienced on foreign account. Girders and also bars are to be bought at prices considerably below list rates, whereas hoops remain in fairly satisfactory demand, consumers being ready enough to buy at the low prices which are ruling at present. Orders for sheets continue to come in very scantily. All sorts of wire and wire nails as well as rivets are depressed. A poor activity is reported at the foundries and machine factories, while the locomotive shops are tolerably well employed, and hope to remain so for the next months, as there are orders for 340 locomotives and 1000 freight cars to be given out by the Government. The Erfurt Railway Administration recently invited tenders for the supply of fish-plates, and the prices asked ranged between M. 110, M. 125, and M. 135·50 p.t. at works.

It has been statistically stated that during the first three quarters of 1894 output of pit coal in Prussia was 52,008,870 t., against 49,668,001 t. in the year before; consumption was 50,281,751 t., against 47,867,922 t. for the same period last year. The number of men employed was 266,348, against 257,128 in the previous year. The production of brown coal during the first three quarters of present year amounted to 16,626,905 t., against 12,721,529 t. in 1893, while consumption was 9,993,619 t., against 10,315,469 t. for the corresponding period of last year; the number of mem employed was 28,576 this year, against 29,519 in last year. Total output of coal in the Ruhr district was, for the first ten months of present year, 28,496,250 t., against 26,716,220 t. for the same period the year before; in the Saar district production was 4,262,310 t., against 3,747,160 t. last year, and in Upper Silesia 9,869,270 t., against 9,801,190 t. in the preceding year. In the three districts together 42,627,830 t. were produced within the first ten months of present year, against 40,264,570 t. for the same period last year, which shows for the Rhenish-Westphalian district an increase of 1,780,030 t. or 6·7 p.c., for the Saar district 515,150 t. or 13·7 p.c., for Upper Silesia 69,080 t. or 0·7 p.c., and for the three districts together an increase of 2,364,260 t. or 5·6 p.c. against the corresponding period in 1893.

## AMERICAN NOTES.

NEW YORK, Nov. 16th, 1894.

THE American iron markets are quiet, and very little inquiry is made concerning winter deliveries. Production is sufficiently heavy in all branches to insure a continuance of present quotations. Girder rails are in good request at 23 dols. to 25 dols.; standard rails at 24 dols. Large orders for 100 lb. rails will soon be placed in the Pennsylvania Rail Mills. Pig iron is quiet. Southern is freely offered here at 10 dols. to 10·25 dols. Bessemer is dull. Steel billets are quiet. Merchant bar mills are short of orders in Eastern Pennysivania, but the Pittsburgh district is well supplied with orders for all kinds of material except steel rails. Prospects are more favourable for large winter delivery orders, especially for billets, skelp, bars, rods, and track supplies. The crushing condemnation of the economic policy of the present Administration has imparted a buoyancy to the trade that will soon be felt in better markets.

THE new Russian ironclads Rostislav and Rossia, building respectively at Nicolaieff and at the Baltic Yard on the Neva, are to be supplied with furnaces suitable for the combustion of petroleum. If experiments with them be successful, similar furnaces will be supplied to other new vessels.

21,452. Electric Fire-alarms, P. R. J. Willis.—(*L A. and C. L. Werner, United States.*)
21,453. Reflectors for Pianos, L. Kilner, London.
21,454. Construction of Clamps, H. de Haven and J. E. McMurray, London.
21,455. Shields for Steam Water Gauges, R. T. Preston, London.
21,456. Heating and Purifying Water, W. H. Blackeney, London.
21,457. Device for Ladies' Muffs, W. Hazlitt, London.
21,458. Doublet Lenses, C. P. Goerz and E. von Höegh, London.
21,459. Coulters, W. H. Sleep and R. H. Sleep, London.
21,460. Wheels, S. E. Saunders, London.
21,461. Electric Motors, C. Riordon, London.
21,462. Mounting Bicycle Wheels, P. Amjörn, London.

*8th November*, 1894.

21,463. Emptying Vessels Containing Treacle, J. S. Green, F. R. Syms, and W. Adams, London.
21,464. Lighting Hydrocarbon Lamps, R. H. Cotter, Co. Limerick.
21,465. Leverage Gearing, G. P. Bartlett, London.
21.466. Adjustable Watch Keys, J. Vale, Birmingham.
21,467. Stop-cock with Draining Outlet, J. F. Whiteside, Lancashire.
21,468. Blacking Bottle and Applier, G. C. Lake, Leamington Spa.
21,469. Combined Lawn Mower, &c , W. J. Stephenson-Peach, Derby.
21,470. Oil Lamps, J. Paul, Glasgow.
21 471. Securing Nuts to Screwed Bolts, W. Harrington, Kidderminster.
21,472. Construction of Portmanteaus, &c., W. P. Cochrane, Newcastle-on-Tyne.
21,473. Key-board of Type-writer, F. and A. Besson, London.
21,474. Support for Infants' Cribs, M. L. Barlow, London.
21,475. Golf Clubs, R. Simpson, Dundee.
21,476. Means of Sanitation, M. E. Melsom, London.
21,477. Acid-resisting Lining for Metallic Vessels, R. Preston and T. Thornley, Manchester.
21,478. Seats of Tramcars, S. Newton, Manchester.
21,479. Milk Measurer and Tester, T. Bevington, Bristol.
21,480. Postcard Advertising Box, T. G. Scott, Liverpool.
21,481. Printing Colours, W. I. Iliffe, J. J. H. Sturmey, and J. Ward, Leicester.
21,482. Apparatus for Ships' Telegraphs, E. Fletcher, Liverpool.
21,483. Lubricant, J. W. Glover and T. Bagnall, Kidderminster.
21,484. Warning Apparatus for Cycles, J. Speir, Glasgow.
21,485. Shuttle Guards, D. and J. H. Pilkington, Rochdale.
21,486. Pearl Button with Inlaid Small Glass Mirrors, W. Frese, Berlin.
21,487. Tires for Road Vehicles, F. B. Biddiscombe, Manchester.
21,488. Bicycles, C. E. Bell, Manchester.
21,489. Railway Track System, E. Deming, Manchester.
21,490. Boots and Shoes, J. Dick, Glasgow.
21,491. Looms for Weaving, The Anderston Foundry Company, Ld., and J. Reeves, Glasgow.
21,492. Cans, R. Read, A. Read, and W. A. Read, Liverpool.
21,493. Cutting the Teeth of Bevel Wheels, J. H. Gibson, Liverpool.
21,494. Joint for Drain and other Purposes, T. E. Coleman, Hampshire.
21,495. Fire-proof Lath for Building Purposes, T. E. Coleman, Hampshire.
21,496. Portiere Rods for Curtains, E. Ward, Southampton.
21,497. Cycle Saddle Elevator, H. Larkings, Warwick.
21,498. Signalling Apparatus, S. R. Kirby and G. W. England, York.
21,499. Making Fishing-rods, E. Perks, Birmingham.
21,500. Draw-bar Attachment, W. Graham, Whitehaven.
21,501. Hair-curling Tongs, L. Myers, Birmingham.
21.502. Manufacture of Churns, H. W. Ludlow, Birmingham.
21,503. Axle Box with Rollers, W. G. H. Sedwell, London.
21,504. Construction of Drums, A. Grey, London.
21,505. Water Bottle, A. E. Wardroper, London.
21,506. Metallic Ends of Lathes, W. Walmsley, London.
21,507. Seamless Steel Tubes, R. Wootton, Birmingham.
21,508. Construction of Ellipsographs, T. Moy, London.
21,509. Apparatus for Ice-making, A. Glasson, London.
21,510. Fog-signalling on Railways, H. A. L. Barry, London.
21,511. Adjustable Wire Gauge, H. V. James, Manchester.
21 512. Grates, E. Scanlan, F. W. Keifel, jun., and J. Zipp, London.
21,513. Dealing with Smoke, F. W. Stevenson, London.
21,514. Draught Excluder for Doors, H. C. Evans, London.
21,515. Files for Letters, C. Durey, London.
21 516. Loom Shuttle Checking Apparatus, J. Woods, London.
21,517. Projectiles, A. Reynolds, London.
21,518. Scaffolds for Buildings, H. Drimer, London.
21,519. Treatment of Wastes, T. H. Cobley and D Scott, London.
21,520. Waste for Papier-mache, T. H. Cobley and D. Scott, London.
21,521. Filtering Appliance for Tobacco Pipes, A. G. Goodes, London.
21,522. Boxes for Storing Parasols, T. H. Simmonds, London.
21,523. Pneumatic Tires, J. Dring, London.
21,524. Thrust Block, S. Pethers, London.
21,525. Paving and Flooring Block, T. H Lewis, London.
21,526. Shelling Eggs, H. Owen, London.
21,527. Apparatus for Cooling Acids, F. W. Berk, London.
21,528. Feed Gear for Ratchet Braces, E. O. Seale, London.
21,529. Production of Vinegar, E. Andreoli, London.
21,530. Doors, A. Sinclair, London.
21,531. Electric Sash Balance, W. C. Hodgkins, London.
21,532. Converting Reciprocating in Rotary Motion, T. Beach, London.
21,533. Production of Curved Printing Plates, A Sauvée, Liverpool.
21,534. Forging Wrought Metal, W. P. Thompson.—(*J. B. West, United States*)
21,535. Aprons, A. W. Hancock and J. Leighton, London.
21,536. Roller Bearings, The Steel Forging and Ball Bearing Company and P. Holyoake, London.
21,537. Mechanical Kneeding Troughs, C. Somasco, London.
21,538. Bottle-cleaning Machines, T. Prioux, London.
21,539. Adjusting Sheets of Paper, H. H. Lake.—(*T. C. Dexter and J. C. Willett, United States*)
21,540. Mechanical Milking Cans, C. G. P. D. Laval, London.
21,541. Ships, S. H. M. Killik and A. Elgar, London.
21,542. Steam Generator, Simpson, Strickland and Co. and F. Strickland, London.
21,543. Water-closets, E. E. Lefevre, London.
21,544. Rotary Paper-cutting Machines, G. Heerbrandt, London.
21,545. Pneumatic Tire, W. Mackintosh, London.
21,546. A Puzzle, B. A. Spaull, London.
21,547. Machine for Bevelling, W. Bridgewater, Leicester.
21,548. Supports for Club Carriers, J. W. Price, London.
21,549. Electrically Heated Robes, H. G. O'Neil and E. Jewell, London.
21,550. Tanning, J. Y. Johnson.—(*F. Kornacher and Diesel and Weise, Germany.*)
21,551. Combined Type-writing Case and Table, F. C. Wood, Philadelphia.
21,522. Water-pressure Feeder, T. B. Smith, Philadelphia.

*9th November*, 1894.

21,553. Cycle Clips, The Roulette Cycle Company and H. Cook, Coventry.
21,554. Velocipedes, F. Ellis, London.
21,555. Secondary Batteries, I. A. Timmis, London.
21,556. Mooring Pipes, J. W. Sampson and T. L. Mitchelmore, Southampton.
21,557. Purifying Chemical Bye-products, A. Walker, Blackburn.
21,558. Adding Machines, G. Browning, Manchester.
21,559. Attachment to Saucers, M. Goffey, Liverpool.
21,560. Laundry Gloves, J. A. Fox and G. J. Moulton, Manchester.
21,561. Tool Holder for Lathes, T. W. Haddon, Birmingham.
21,562. Cheque Value Indicator, W. Triggs, Preston.
21,563. Billiard Marking Board, E. Kaltenach, Wigan.
21,564. Loom Shuttles, J. Riley, Bradford.
21,565. Cast Metallic Chain, E. F. H. Barnsley, Birmingham.
21,566. Valve or Clack Seating for Pumps, B. E. Goddard, Newcastle, Staffs.
21,567. Tire Covers, W. H. Cresswell, H. E. Cohen, and A. W. Latimer, Cheshire.
21,568. Round Tin Frame, J. Harvey, Cornwall.
21,569. Address Cards, E. H. Godbold and F. Westwood, Birmingham.
21,570. Washers for Bolts, W. E. Heys.—(*C. Bristow, New Zealand.*)
21,571. Steam Traps, W. Geipel, London.
21,572. Pneumatic Cycle Tires, A. T. Andrews, Birmingham.
21,573. Photographic Dark Slides, E. A. Whitby, London.
21,574. Gas Burners, C. B. Voisey, E. W. T. Richmond, and Richmond and Co., Liverpool.
21,575. An Automatic Arithmometer, O. A. Elias, London.
21,576. Heeling Machinery, W. H. Dorman, Stafford.
21,577. Washing Printers' Blanketing, W. Hadfield, J. J. Sumner, and H. Hadfield, Manchester.
21,578. Flexible Tubing or Hose, F. Reddaway, Manchester.
21,579. Safety Pins or Hooks, C. Crowther, Manchester.
21,580. Fixing Watertight Sheets, H. D. and J. A. Hope, London.
21,581. Starting of Gas Engines, E. A. Cunningham, Nailsworth, Glos.
21,582. Gas Globe Holder, S. H. Keeling and H. M. Picken, Birmingham.
21,583. Link Belting, J. D. Walton, Glasgow.
21,584. Engine Governors, J. Buchan, Glasgow.
21,585. Watch Guard, D. Fulton and J. Robertson, Lanarkshire.
21,586. Manufacture of Asphalt Blocks, M. Williams, Liverpool.
21,587. Hanging Window Sashes, H. Champness, Bishop's Stortford.
21,588. Sewing Thimbles, T. S. Greenway, Wolverhampton.
21,589. Pills, T. Tildesley, London.
21,590. Fencing, T. S. Greenway, Wolverhampton.
21,591. Mounting of Tinted Photographs, A. Findlow, London.
21,592. Printing Waterproof Fabrics, T. Birnbaum, London.
21,593. Bicycle Driving Apparatus, T. W. Stockhill, Hull.
21,594. Paper Coating Apparatus, A. W. Loveland, London.
21,595. Portiere Rods, G. H. Brown, Birmingham.
21,596. Cycle Lock, F. Hofmanrichter, London.
21,597. Clip for Composite Collars, E. B. Styring, Poole.
21,598. Apparatus for Shipping Coal, &c., J. P. Roe, London.
21,599. Appliances for Conveying Coal, J. P. Roe, London.
21,600. Almanac, G. Siller, London.
21,601. Ship Manœuvring Apparatus, W. S. Simpson, London.
21,602. Making Fishing Lines with Floats, F. P. Dobell, Isle of Wight.
21,603. Bread Tins, W. Hammill, W. A. Servant, A. J. Fish, and C. Mould, London.
21 604. Boxes for Tobacco and Snuff, G. H. Williamson, London.
21,605. Lamps for Burning Oil or Spirit, A. Kiesow, London.
21,606. Locking Nuts, T. C. Roussel, London.
21,607. Printing Textile Material, S. H. Sharp, London.
21,608. Construction of Wheels for Vehicles, R. Storey, London.
21,609. Portable Folding Game Tables, D. S. Grant, London.
21,610. Frames for Holding Pictures, H. C. Vinicombe, London.
21,611. Windows, T. M. Houghton, Glasgow.
21,612. Lacing Eye for Boots and Shoes, W. Brown, London.
21,613. Telephones, E. C. Parker, London.
21,614. Manufacture of Carpets, &c., J. S. Baxter, London.
21,615. Construction of Thermometers, J. B. Lee, London.
21,616. Boot Sewing Machines, J. Y. Johnson.—(*The Deutsch-Amerikanische Maschinen-Gesellschaft, Germany*)
21,617. Brake Blocks, G. T. Mackley, London.
21,618. Opening and Closing Joints, W. McCowan, Reading.
21,619. Ball Bearing, J. W. Howard, London.
21,620. Tooth-brush with Movable Back, L. Ehrlich, Berlin.
21,621. Lamp Chimneys, C. Günther, Berlin.
21,622 Fire Blower, R. W. McGregor and G. A. McDowall, London.
21,623. Stamps, H. Bernert, London.
21,624. Musical Apparatus, A. V. Tims and J. H. Holmes, London.
21,625. Appliances for Signalling at Sea, W. H. Owen, London.
21,626. Construction of Studs, &c., A J. B. Church, London.
21,627. Storm Lanterns, E. Sommerfeld, London.
21,628. Regenerative Gas Burner, J. Haeussler, London.
21,629. Electric Railways, L. Hanisch and the Hoerder Bergwerks and Hütten-Verein, London.
21,630. Electric Meters, H Leupold.—(*H. Leupold, Italy.*)
21,631. Drying Kilns, E. Orval, London.
21,632. Cycle Handle Bars and Forks, E. Verschave fils, London.
21,633. Evaporating Apparatus, H. H. Lake.—(*H. See, United States.*)
21,634. Clothes Washing Machine, F. G. Sherer, London.
21,635. Sewage Precipitation, W. E. Adeney and W. K. Parry, London.
21,636 Carriages for Lawn Mowers, W. P. Green, London.
21,637. Clip for Holding Papers, &c., B. F. Bryant, London.
21.638. Trawling Nets, A. Johnson and C. A. Nielsen, London.
21,639. Knitting Machines, W. F. Fair, London.
21,640. Electric Switches, G. J. Gurl, London.
21,641. Gear Cases for Velocipedes, P. Hunaeu London.
21,642. Mud Guards for Velocipedes, P. Hunaeus, London.
21,643. Corrugated Strip, C. J. Smart and F. Gwynne, London.
21,644. Corrugating Cardboard Strips, C. J. Smart, London.
21,645. Steam Engines, H. Cambridge, London.
21,646. Attaching Purses to Wrists, L. Edwards, London.

*10th November*, 1894.

21,647. Umbrella Identifying Device, J. S. Martin, London.
21,648. Bread, W. Adair, Waterford.
21,649. Bread, W. Adair, Waterford.
21,650. Bakers' Ovens and Apparatus, W. Adair, Waterford.
21,651. Adjusting Governors, J. Hughes and C. Hill, London.
21,652. Fly-wheel Governor, J. Hughes and C. Hill, London.
21,653. Tobacco Pipe, W. B. Wallace, Woolwich.
21,654. Syphon Flushing Cistern, W. Wheeler, Langley.
21,655. Gas Producers, E. J. Duff, Manchester.
21,656. Placing Detonators on Railways, A. Flory, Knowle.
21,657. Hat Fastener, M. Martin and G. Gregg Nottingham.
21,658. Treating Brewers' Spent Hops, J. J. Adkins, London.
21,659. Toasting Fork Handles, &c., G. A Savile, Harrogate.
21,660. Atmospheric Gas Heaters, F. W. Zimer, London.
21.661. Dress Suspenders, A. G. Horne and J. Samuel, Glasgow.
21,662. Collapsible Boxes, D. Y. Annan, Dundee.
21,663. Spring Floor, T. Freeman, J. H. Shaw, and W. A. McCrum, Dublin.
21,664. Boot, W. J. Nash, Dublin.
21,665. Sugar Boilers' Rock Chopper, H. Cooper, Rhondda Valley.
21,666. Parts of the Wheels of Vehicles, H. W. James, Birmingham.
21,667. Carrying Tanks, J. McL. McMurtrie and Lucal, Glasgow.
21,668. Conveyors for Coal Dross, &c., T. Thomson, Glasgow.
21,669. Drilling Machines, W. A. Smith, P. Rottenburg, and W. C. Fischer, Glasgow.
21,670. Padlocks, T. C. Dowd, Wednesfield.
21,671. Rear-driving Geared Bicycles, E. Jackson, Prescot.
21,672. Crochet and Knitting Needle, J. A. Burton, Nottingham.
21,673. Securing Pneumatic Tires, S. J. Cockbain, Halifax.
21 674. Manufacture of Boots and Shoes, H. Tilley, Leicester.
21,675. Wheel Rims, S. Morgan and F. T. Jackson, Leicester.
21,676. Latches for Doors and the like, C. Showell, Birmingham.
21,677. Hair Curlers, H. W. Tonks, Birmingham.
21,678. Hame Tackle or Fittings, T. W. Mills, Birmingham.
21,679. Gas Fittings, J. Grubb and W. Robinson, Birmingham.
21,680. Perrymeters, J. P. O'Donnell.—(*L. F. Johnson, United States.*)
21,681. Filtering Boiler Feed-water, R. Risk, Glasgow.
21,682. Water-closet, J. Shanks, Glasgow.
21,683. Corliss Valves, J. H. Hargreaves and J. G. Hudson, Glasgow.
21,684. Indicator, H. Dando.—(*H. A. Dando, New Zealand.*)
21,685. Anti-syphon Pipes for Water-closets, W. Tate, London.
21,686. Gear for Swings, E. Williams and G. F. Pennington, Castleford.
21,687. Reel, Needle, and Thimble Holder, W. R. Manders, Hoylake.
21,688. Accordion Valves, T. R. Shillito.—(*O Spaethe, Germany.*)
21,689. Vices, B. Mountain, Leeds.
21,690. Friction Clutches and the like, B. Mountain, Leeds.
21,691. Portable Letter Copying Presses, J. Marshall, Glasgow.
21,692. Crest Tiles, R. N. Allen, Birmingham.
21,693. Knife-cleaning Machine, E. E. and A. W. Boothby and G. J. A. Comont, London.
21,694. Legging Fasteners, H. A. Wickham and S. Edwards, London.
21,695 Re-squaring Plates, W. Williams and W. G. Morris, London.
21,696. Washing and Wringing Machine, J. Miles, London.
21,697. Gas Stoves, T. Hadfield, London.
21,698. Gas-fired Steam Boilers, G. H. Taylor, London.
21,699. Filling Bottles, W. P. Thompson.—(*J. C. Gelly, Australia*)
21,700. Typewriters, J. S. Foley, London.
21,701. Cycle Fittings, H. Lucas, London.
21,702. Funnels, F. Rudd, London.
21,703. Tobacco Pipe Cleaner, W. Simon, London.
21,704. Floors for Billiard-rooms, W. W. Burnett, London.
21,705. Cycle Saddles, R. S. Lovelace, London.
21,706. Velocipedes, G. L. Morris, London.
21,707. Electric Conductors, A. Slater.—(*J. Platt, United States.*)
21,708. Starch and Starchy Substances, C H. Meyer, London.
21,709. Showing Signals All Round, G. Blakeley, Bournemouth.
21,710. Cheese, C. F. Hope, Weymouth.
21,711. Exhibiting Device, H. H. Leigh.—(*The Celluloid Company, United States*)
21,712. Liquid Meters, C. S. Brough and W. Brough, London.
21,713. Wire Chains, F. W. Smith.—(*The Smith and Egge Manufacturing Company, United States.*)
21,714. Sewer and Surface Box Covers, E. J. Preston, London.
21,715. Washing Machine, P. K. J. Willis.—(*A. A. Wright, United States.*)
21,716. Continuous Rolling Process, &c., O. Klatte, London.
21,717. Blind Pulleys, T. W. and F. C. Tidmarsh, London.
21,718. Fashion Plates, P. M. Justice.—(*D. A. Morse, United States*)
21,719. Treadle or Crank Movement, L. S. Manning, London.
21,720. Vertical Rolls for Grooved Rails, G. Trasenster, London.
21,721. Rolling Grooved Rails, &c., G. Trasenster, London.
21,722. Finger Plates and Panels, J. C. Woolstone, London.
21,723. Freezing Machines, W. G. Scott, London.
21,724. Advertising, A. F. E. de St. Dalmas, London.
21,725. Stands, A. F. E and W. H. E. de St. Dalmas and A. F. Cholerton, London.
21,726. Boots and Shoes, E. J. Hammond, London.
21,727. Knitting Machine, L. N. D. Williams and R. W. Scott, London.
21,728. Type Matrices, J. Y. Johnson.—(*A. S. Capehart, United States.*)
21,729. Manufacture of Nitro-cellulose, J. W. Swan, London.
21,730. Perfumes, B. Willcox.—(*M. Otto and A. Verdi, France.*)
21,731. Arc Lamps, C. A. Day.—(*G. J. Schoeffel, United States.*)
21,732. Alkali Cyanides, H. Y. Castner, London.
21,733. Writing Pad, C. E. Gunn, London.
21,734. Stone Cements, E. Weckwarth and M. Hoeft, London.
21,735. Lime Mixtures, E. Weckwarth and M. Hoeft, London.
21,736. Groynes, H. E. Stilgoe, London.
21,737. Machines for Printing Linoleum, C. H. Scott, London.
21,738. Packing Matches, C. J. Bolinder, O. L. Borg, and M. Kjellberg, London.
21,739. Balling Yarns, Threads, &c., E. P. Alderson, London.
21,740. Locking Devices for Cones, G. Gibson, Newcastle-on-Tyne.
21,741. Motive Power Engines, J. G. L. McLachlan, Glasgow.
21,742. Whips, M. Müller, Cologne.
21,743. Typewriting Machines, E. Fitch, London.
21,744. Metallic Strapping for Boxes, H. de Haven, London.
21,745. Surveying Instruments, &c., D. Arámburn, London.
21,746. Milk Cans, H. Fearncombe and Co. and A. Evans, London.
21,747. Receptacles for Holding Labels, W. Jones, London.
21,748. Steering Lock, F. Maly and G. Valencsak, London.
21,749. Combination Corn Sacks, M. F. Rimington, London.
21,750. Arc Lamps, J. W. Rogers, London.
21,751. Spoons, J. Earle, London.

*12th November*, 1894.

21,752. Device for Holding Watches, A. D. Blaxland, London.
21,753. Retaining Hats on the Head, M. H. Jackson, London.
21,754. Button-hole, M. H. Jackson, London.
21,755. Suspenders for Miners' Lamps, T. L. James, Pontypool.
21,756. Coin-freed Mechanism, G. S. Smith, G. Haydon, and F. H. Urry, London.
21,757. Velocipedes, F. Westwood, Birmingham.
21,758. Looms, R. Wilkinson, Manchester.
21,759. Stereophotorama, W. Ashton, Southport.
21,760. Metallic Fittings of Waistbelts, W. M. Harris, Birmingham.
21,761. Bedsteads, W. E. Nichols and R. Pitt, Birmingham.
21,762. Holders for Twine, Cord, or Tape, A. Cole, Dublin.
21,763. Portable Water-container for Birds, H. Edge, Longport.
21,764. Tramway Vehicles, J. Darling, A. R. Harvey, and R. C. Lyness, Glasgow.
21,765. Pneumatic Tires and Covers, J. Hague, Manchester.
21,766. Sad Irons, W. J. Fox, Manchester.
21,767. Vertical Grand Pianos, F. Schimmel and S. F. Nelson, Manchester.
21,768. Hair Curlers, G. H. Twigg, Birmingham.
21,769. Safety Pins, H. W. Tonks, Birmingham.
21,770. Velocipede, J. B. Johnston, Manchester.
21,771. Device for Printing Machines, J. S. Howden, Liverpool.
21,772. Aerial Navigation Apparatus, A. J. Lehmann, Liverpool.
21,773. Tubes for Velocipedes, R. Howarth, Wolverhampton.
21,774. Production of Caustic Soda, M. N. d'Andria, Stretford.
21,775. Drilling Boiler Shells, A. Muir, Manchester.
21,776. Letter-boxes, E. Miles, Swansea.
21,777. Paper Tubes for Cartridges, G. Kynoch and Co. and E. Jones, London.
21,778. Concentration of Sulphuric Acid, I. S. McDougall, London.
21,779. Adjustable Bearings, R. Wallwork, Manchester.
21,780. Apparatus for Testing Drain Pipes, &c., A. Harkess, Edinburgh.
21,781. Oil or Gas Heating Apparatus, G. Quadling, East Dereham.
21,782. Automatic Electrical Rheostats, T. Caink, Worcester.
21,783. Moulding for Framing Cards, J. Fallas, Wakefield.
21,784. Non-slipping Pneumatic Tires, T. P. Hennessy, Dublin.
21,785. Handles for Children's Carriages, G. J. Smith, Birmingham.
21,786. Colouring Matters, A. G. Green and R. Jansen, Manchester.
21,787. Colouring Matters, A. G. Green and F. Jansen, Manchester.
21,788. Colouring Matters, A. G. Green and R. Jansen, Manchester.
21,789. Music Leaf-turners, S. Stephenson and C. Wilson, Sheffield.
21,790. Firelighters, S. Vint, London.
21,791. Key-ring, H. A. Long, London.
21,792. Doors and Gates, J. T. Lane and F. Albon, London.
21,793. Shooting Swivel Tube, W. Brookes, Cardiff.
21,794. Boots and Shoes, J. W. Ellis and W. J. Burrows, Leeds.
21,795. Picker Presses, J. Muir, Glasgow.
21,796. Shafts for Bassinettes, W. S. Dove, Glasgow.

21,797. Window Fastener, E. L. Godfrey and W. C. Butlin, Stonehouse.
21,798. Converting Reciprocating Motion, E. Rollason, Birmingham.
21,799. Measure-graph, H. J. H. Graves, Devonport.
21,800. Final, A. Jeffery, Bradford-on-Avon.
21,801. Ladders, C. A. Sabow, London.
21,802. Speed-changing Gear Trains, J. Thomson, London.
21,803. Shoal Indicators for Bridge Alarms, S. H. James, London.
21,804. Money Holder, W. A. Torge, London.
21,805. Pickers and Picker Staves, J. Rubirola, London.
21,806. Determining Altitudes, O. Eckenstein and L. A. Legros, London.
21,807. Affixing Taps or Valves, F. P. Munro, London.
21,808. Observing the Aspect of the Heavens, R. A. Gregory, London.
21,809. Fish-plates, &c., for Railways, R. Meusel, London.
21,810. Beating Fibrous Substances, T. Burrows and D. Radclyffe, London.
21,811. Spinning Fibrous Substances, T. Burrows and D. Radclyffe, London.
21,812. Vehicle Wheels, J. Bonn, London.
21,813. Locks, A. T. Tucker, London.
21,814. Electric Arc Lamps, J. Torge, London.
21,815. Making Parasite Tincture, A. B. F. Wegemund, London.
21,816. Heating Furnaces with Coal Dust, F. de Camp, London.
21,817. Tobacco Pipe, C. Hyatt-Woolf and A. E. Hayman, London.
21,818. Improved Pneumatic Inkstand, J. Stibor, London.
21,819. Heating Apparatus, R. E. Roberts, Essex.
21,820. Armour Plates, A. H. Smith, London.
21,821. Electro-motors, T. Parker, Ld., and T. Parker, London.
21,822. Alloying of Metals, J. C. Mewburn.—(*The Firm of F. Hornig and W. Borchers, Germany.*)
21,823. Safety Bolt Stirrup, T. H. Duncombe, London.
21,824. Belts, W. B. Fosdick, London.
21,825. An Improved Claw Hammer, W. H. Burgess, London.
21,826. Taps for Steam, &c., Liquids, J. Rombach, London.
21,827. Exciting Dynamo-electric Generators, J. Imbray.—(*La Société Anonyme pour la transmission de la force par L'électricité, France.*)
21,828. Moulding Tees, J. Osmond, London.
21,829. Working Gas Engines, C. D. Abel.—(*The Gasmotoren Fabrik Deutz, Germany.*)
21,830. Milk Separators, C. D. Abel.—(*Messrs. Drosse and Ludloff, Germany.*)
21,831. Buttons, E. J. Stonier, London.
21,832. Manufacture of Boots, J. Robinson and G. Wilson, London.
21,833. Grinding Machine, G. Heerbrandt, London.
21,834. Cash-registering Apparatus, H. H. Lake.—(*The Victor Cash Register Company, United States.*)
21,835. Safety Roller-brake, A. Bradford, London.
21,836. Surveying Instruments, M. H. P. R. Sankey.—(*F. W. Moffitt, India.*)
21,837. Apparatus for Boiling Sugar, T. Moore, J. A. Sanders and W. H. Percy, London.
21,838. Electrolysing Chemical Combinations, W. Bein, London.
21,839. Dumping Wagons, D. Young.—(*W. R. Bell, South Africa.*)
21,840. Bolts, W. M. Levering, London.
21,841. Combined Cushion and Syringe, P. R. J. Willis.—(*Joseph La Londe, Canada.*)
21,842. Device for Taking of Pills, A. Bowles, London.
21,843. Photographic Cameras, A. J. Boult.—(*A. Lefebure, France.*)
21,844. Devices for Holding Tools, W. Chandler, London.
21,845. Dry Batteries, R. Myers, London.
21,846. Spooling Machines, J. Wales, London.
21,847. Cryptograph, W. P. Thompson.—(*G. Strömdal and J. von Ditten, Norway.*)
21,848. Fixing Adhesive Labels, F. Meyer, London.
21,849. Roundabouts, J. W. Radford and H. Hallam, London.
21,850. Inducing Custom in Shops, M. M. Dessau, London.
21,851. Rolls for Grooved Rails, G. Trasenster, London.
21,852. Gripping Device, F. Harrington, London.
21,853. Fabric Receiver, P. Dunn, Birmingham.

13th *November*, 1894

21,854. Venetian Blind, T. Brown, Essex.
21,855. Tools for Trueing-up, W. P. Adams and R. E. B. Crompton, London.
21,856. Automatic Railway Engine, T. Pearson, Middlesbrough.
21,857. Abacus, J. H. Towers, Southsea.
21,858. Cycles with Springs, C. Hassel, Manchester.
21,859. Appliance for Boiling Water, G. H. McKay, Glasgow.
21,860. Endless Bands, J. T. Southworth and C. Macintosh and Co., Manchester.
21,861. Damping Warps, A. Sutcliffe, Blackburn.
21,862. Draught Excluders, A. Gregson, Manchester.
21,863. Cycle Lamp Bracket, J. E. Meredith, Birmingham.
21,864. Making Buckets or Pails, D. Potts, Liverpool.
21,865. Cycle Tires, R. A. Vogt and L. P. Vogt, Glasgow.
21,866. Fencing Wire Fixings, W. T. Eades and H. W. Henley, Birmingham.
21,867. Speaking Tubes, H. A. Cutmore, London.
21,868. Wheel Tires, J. Andrew, Glasgow.
21,869. Boat-launching Arrangement, J. B. Forster, Newcastle-on-Tyne.
21,870. Culinary Utensils, C. E. Challis, London.
21,871. Securing Taps in Casks, H. Edwards and E. S. Smith, Bristol.
21,872. Vulcanising India-rubber, J. T. Southworth and C. Macintosh and Co., Ld., Manchester.
21,873. Driving Gear for Cycles, W. G. Harris, Bristol.
21 874. Wind-resisting Match-box Case, W. H. Salmon, Kent.
21,875. Sheep-shearing Machine, C. W. Pitman, London.
21,876. Bolts for Fastening Doors, J. Whitehead, Birmingham.
21,877. Steel Band and Wire Clip, W. Chivers, Bristol.
21,878. Displaying Advertisements, R. D. Bailey, London.
21,879. Electro-fusion of Metals, B. H. Thwaite and H. Allen, London.
21,880. Rocking and other Chairs, W. S. McLennan, Glasgow.
21 881. Wheels for Cycles, &c., F. Day and J. Jones, Dudley.
21,882. Revolving Theatrical Bed, T. B. Stuart, Salford.
21,883. Bottle Stoppers, J. G. Liversidge and W. Snowdon, Leeds.
21,884. Roller Brake, J. Drew and R. McVittie, Edinburgh.
21,885. Brake for Pneumatic Wheels, J. Ayliffe and W. H. Davies, Cardiff.
21,886. Velocipedes, E. Immer, Manchester.
21,887. Drinking Glass Stands, J. H. F. Kickhefel, Glasgow.
21,888. Driving Chains, S. T. Richardson, A. Smallwood, and R. Price, Birmingham.
21,889. Gear Cases, S. T. Richardson, A. Smallwood, and R. Price, Birmingham.
21,890. Cycle Cranks and Connections, F. E. Jones, Birmingham.
21,891. Top Boot and Shoe for Horses, &c., T. Clegg, Leeds.
21,892. Envelopes and Post-cards, W. H. Schwartz, London.
21,893. Autographic Telegraphs, J. O'Neil, London.
21,894. Garment Stretcher, L. Mallory, London.
21,895. Button Fastener, C. A. Allison.—(*I. J. Saunders, United States.*)
21,896. Target Facings, A. J. Altman, London.
21,897. Fire Escapes, W. Threlfall, London.
21,898. Slate Cleaner, J. E. Phillips, London.
21,899. Weft-fork Holders for Looms, J. and J. Nutter, London.
21,900. Loom Checking Appliances, T. Fielden and D. Askham, London.
21,901. Dolls' Houses, H. F. Robinson, London.
21,902. Steering of Vessels, A. J. Boult.—(*H. Demnitz, Germany.*)
21,903. Pianos, W. P. Thompson.—(*M. H. McChesney and J. G. Kunze, United States.*)
21,904. Gates, S. J. Smith, London.
21,905. Metallic Keys for Railways, P. Colombier, Liverpool.
21,906. Passenger Vessels, W. F. Hart.—(*A. McDougall, United States.*)
21,907. Fastening Driving Belts, D. Michie, London.
21,908. Burner for Essences or Perfumes, H. Krey, London.
21,909. Sectional Neckties, D. Sanguinette, London.
21,910. Brushes, W. Wallach, London.
21,911. Locomotive Draught Apparatus, R. Weatherburn, London.
21,912. Quoins for Printers' Formes, T. Ashford, London.
21,913. Treatment of Locust Beans, C. D. Ekman and C. Christian, London.
21,914. Feed-water for Steam Boilers, T. Wigley, London.
21,915. Lamp Brackets, J. Nelson and C. H. Edmed, London.
21,916. Lamp Shade Carrier, J. Nelson and C. H. Edmed, London.
21,917. Looking-glass and Writing-desk, J. Weeks, London.
21,918. Shifting Wrenches or Spanners, J. Brown, London.
21,919. Chinebrite, M. Borgenicht, London.
21,920. Washing Casks, C. Pontifex and A. Pontifex, London.
21,921. Destroying Refuse, W. Smethurst and J. Van der Crab, London.
21,922. Pianoforte Actions, G. Hermann, London.
21,923. Steam Whistles, R. Haddan.—(*J. G. Hermes, United States.*)
21,924. Brake Gear of Velocipedes, M. Macer, London.
21,925. Apparatus for Rolling Ink, J. E. Y. Hindle, Wolverton.
21,926. Tobacco Pipes and the like, H. W. C. Harvey, London.
21,927. Apparatus for Recording Music, A. Rivoire, London.
21,928. Heeling Boots and Shoes, H. B. Corney, London.
21,929. Electric Current Regulators, H. V. Keeson, London.
21,930. Card Receptacles, W. Fullerton.—(*H. G. Klenze, United States.*)
21,931. Method of Washing, &c., Ores, C. F. Pike, London.
21,932. Cowl for Railway Carriages, E. Buchholz, London.
21,933. Bookbinding, W. Wilson, London.
21,934. Cask-making Machines, H. H. Lake.—(*W. Ritter, Germany.*)
21,935. Cask-making Machines, H. H. Lake.—(*C. W. O. Erichson, Germany.*)
21,936. Water Meters, J. E. A. Bel, London.
21,937. Ventilating Drains and Sewers, J. Barber, London.
21,938. Connecting Horses to Carts, T. H. Brigg, London.
21,939. Fountain Pens, J. P. Bayly.—(*A. Horstmann, South Africa.*)
21,940. Cycle Driving Gear, A. J. Boult.—(*H. Steudel, Germany.*)
21,941. Hollow Walls, H. Shepherd, London.
21,942. Hydraulic Drawing Press, L. Schuler, London.
21,943. Making Roofing Tiles, G. Krebs and A. Wiel, London.
21,944. Crankshafts and Bearings, A. A. Pope, London.
21,945. Decomposing Apparatus, W. Thomson and P. J. Worsley, London.
21,946. Furnaces, W. Thomson and P. J. Worsley, London.
21,947. Drying Textile Fabrics, J. B. Jackson and G. Bentley, London.
21,948. Electric Lamp Holders, J. Y. Johnson.—(*A. Swan, United States.*)
21,949. Case for Advertising Medium, J. T. Lawrence, London.
21,950. The Ball-bearing Castors, F. A. S. Foale, London.
21,951. Lamps and Bells for Cycles, J. P. Rees, London.
21,952. Construction of Ships, R. and L. Roper, London.

14th *November*, 1894.

21,953. Riding Breeches, F. Heafield, London.
21,954. Boxes, E. H. Durnford, Dartford.
21,955. Locking Drawers, Cabinets, &c., F. Ransom, London.
21,956. Waste Preventer for Taps, F. W. Ventris, London.
21,957. Photographic Lenses, G. Prescott, Dublin.
21,958. Remedy for Sea-sickness, W. G. Waldron.—(*H. Brown, England.*)
21,959. Cycles, T. H. Collingbourne and W. H. McLauchlan, Coventry.
21,960. Nap-raising Machines, W. Holland, Manchester.
21,961. Sick-room Indicator, W. G. Webb, Lichfield.
21,962. Making Ferric Sulphate, W. Wyld and J. H. Cox, Bradford.
21,963. Making Ferric Sulphate, W. Wyld and J. H. Cox, Bradford.
21,964. Tires, E. H. Seddon, Manchester.
21,965. Apparatus for Games, W. D. Bellasis, Birmingham.
21,966. Hook-and-eye Tape for Dresses, W. Lumb, Leeds.
21,967. Music Leaf Holders, J. Dighton, Manchester.
21,968. Photographic Cameras, C. C. Vevers, Leeds.
21,969. Levelling Rollers, C. E. Roberts, W. T. Kirkman, and H. Doughty, Liverpool.
21,970. Gully Dish and Grate, F. Thackeray, Darwen.
21,971. Fireplaces and Stoves, E. H. Shorland, Manchester.
21,972. Vehicle Jack, R. H. Foster, Hebburn-on-Tyne.
21,973. Supporting Vessels on Globes, F. H. and H. Barwell, and H. P. Kimberley, Birmingham.
21,974. Securing Glass Founts, F. H. and H. Barwell, H. P. Kimberley, and J. F. Smith, Birmingham.
21,975. Wrapping Card Fillets, F. G. Dransfield, Manchester.
21,976. Drawing and Measuring, T. F. Johanson and H. R. Kerr, Glasgow.
21,977. Axle-box Caps for Vehicles, J. Latham, Sheffield.
21,978. Pocket Knives, J. Wingfield, Sheffield.
21,979. Extracting Metals, H. Blackwell, jun., A. Schimmel, and G. A. Warburton, London.
21,980. Frames for Baking Purposes, T. Fletcher, London.
21,981. Dough-kneading Machinery, T. Fletcher, London.
21,982. Candle Holder, J. P. Croft and J. C. Phillips, London.
21,983. Cycle Fittings, J. M. and W. Starley, London.
21,984. Centrifugal Churns, S. Cheeld, Bucks.
21,985. Cushion-tired Skates, &c., F. Jones, London.
21,986. Storage Chambers, A. Smith, London.
21,987. A Book for Tracing Music, J. M. Bell, Glasgow.
21,988. Potato Raising Machine, H. Hope and R. Paxton, Glasgow.
21,989. Set Collar for Shafting, &c., G. R. Phipps, London.
21,990. Saddles for Cycles, &c., W. Brampton, Birmingham.
21,991. Electric Tramways and Vehicles, H. Edmunds, London.
21,992. Coal Mines, G. Pickhardt, London.
21,993. Boots and Shoes, D. Tuley, London.
21,994. Refrigerators for Liquids, B. Böggild, London.
21,995. Measuring Substances, T. Christy.—(*K. Tschanter, Germany.*)
21,996. Extractors for Drawing Beer, S. F. Cousins, London.
21,997. Game, W. B. Bust, London.
21,998. Toasting Fork, H. Fairbrother, London.
21,999. Roller and other Wheel Skates, C. Holt, London.
22,000. Fog-signalling Apparatus, F. Fish, London.
22,001. Fireproof Construction, &c., W. Youlten, London.
22,002. Armour-plates, A. J. Boult.—(*P. R. de F. D'Humy, United States.*)
22,003. Ventilating Ships' Cabins, S. V. Walters, Liverpool.
22,004. Finishing Textile Fabrics, T. R. Hanmer, Manchester.
22,005. Safety Lamps, R. Hay, H. Toal, and T. Lowther, London.
22,006. Hats, P. Garton, Liverpool.
22,007. Valves, Pipe Couplings, &c., C. H. Gray, London.
22,008. Kilns, C. D., A. D., and S. D. d'Enghien, London.
22,009. Injectors, L. Gunn, London.
22,010. Toy, L. A. L. and A. L. Delatour, London.
22,011. Utilising the Flow of Tidal Waters, J. E. Liardet, London.
22 012. Fire-grates, H. Hunt, London.
22,013. Developing Photographic Plates, C. E. Hearson, London.
22,014. Preparing Objects for the Microscope, C. E. Hearson, London.
22,015. Saw-horses, E. T. Hughes.—(*C. D. Snell, United States.*)
22 016. Links for Securing Traces, &c., A. Wood, London.
22,017. Tires, G. J. Stevens, London.
22,018. Making Margarine, J. H. Theberath and A. de Kunwald, London.
22,019. Making Nitro-cellulose, F. Greening, jun., London.
22,020. Preserving Ships' Bottoms, A. Tolhurst, London.
22,021. Cycles, G. B. H. Austin, London.
22,022. Machinery for Propelling Vehicles, H. Lane, London.
22,023. Manufacture of Alloys, &c., H. Moissan, London.
22,024. Joints of Earthenware Pipes, J. Farler, London.
22,025. Velocipede Pedals and Boots, J. Keen, London.
22,026. Spinning-mules, P. Jensen.—(*A. Kremer, Luxemburg.*)
22,027. Lanterns, J. Guiraud, London.
22,028. Manufacture of Humic Acid, L. Gautreau, E. Charbonnier, and E. Serrant, London.
22,029. Fans, J. H. Pickup and J. H. Hindle, London.
22,030. Electrically Propelled Carriages, F. King, London.
22,031. Envelopes or Wrappers, &c., G. Porter, London.
22,032. Gravity Motors, L. Gunn and M. G. E. Cuddon, London.

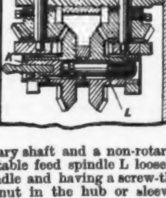
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**525,385.** Pipe-drilling Device, *J. E. Feeling, Malden, Mass.—Filed May 16th*, 1894.

*Claim.*—The herein-described pipe-drilling device consisting of a frame having journalled therein a drill rotary shaft C and a drill feed shaft D combined with a rotary and longitudinally adjustable drill spindle K arranged within the sleeve or hub of a gear actuated by the drill rotary shaft and a non-rotary and longitudinally adjustable feed spindle L loosely connected to the drill spindle and having a screw-threaded end working in a nut in the hub or sleeve of a gear actuated by the feed shaft substantially as and for the purpose set forth.

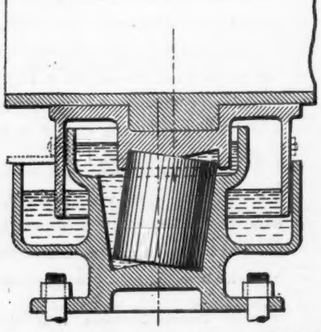
525,383



**525,411.** Sealing, Lubricating, and Bearing Support for Gyrating Screens, &c., *P. W. Gates, Chicago, Ill.—Filed November 10th*, 1893.

*Claim.*—(1) The combination of one or more connecting and supporting plates, each having a dust sealing flange, and an upper seat for a gyrating bearing, a base portion constructed with a chamber for holding a sealing fluid, and a lubricant holding and bearing chamber having a lower seat for a gyrating bearing, substantially as and for the purpose set forth. (2) The combination of the upwardly flared bearing chamber having a seat for a gyrating bearing, and an enlarging upward extension, with a plate having an upper seat for a gyrating bearing, said seat being formed in a downwardly extended projection which is laterally enclosed or surrounded by the upper extension of the bearing chamber, substantially as described. (3) The combination of a gyrating screening device attached to supporting and sealing plates forming upper seats for gyrating bearings, base-supporting portions forming lower seats for the gyrating bearings, and a bearing and oil bath-lubricating chamber, substantially as described.

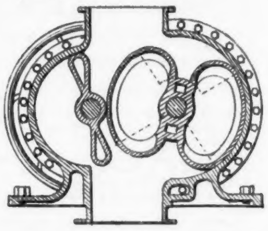
525,411.



**525,532.** Rotary Motor, *A. Clement, San Francisco, Cal.—Filed May 22nd*, 1893.

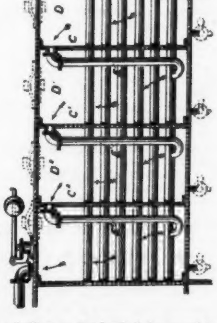
*Claim.*—An improved rotary motor consisting of a shell or case consisting of opposing segments of different radius and curvature with an inlet passage at its upper end and an outlet passage opposite to it at its lower end, a piston mounted in the smaller segment of the case and composed of oppositely radiating wings, each of which is convex near the point, concave in the base, and convex again in the hub; a drum revoluble in the larger segment, having recesses on diametrically opposite sides provided with convex walls to coincide with the ends of the piston wings which are curved to make a rolling contact there with when they pass, while the intermediate connecting curved surfaces of the piston are adapted to conform to the convex portions of the drum with a continuous rolling contact.

525,532



**525,551.** Feed-water Heater, *H. G. Kreasbey, Ambler, Pa.—Filed January 18th*, 1894.

*Claim.*—A feed-water heater and purifier consisting of the shell A, having flues therein, one extremity of said flues terminating in a chamber at one end of said shell, said chamber being provided with a stack G, the other end of said shell being in communication with the flues of a boiler, and adapted to receive the products of combustion therefrom, portions C, C′, and C² in said shell-forming water chambers D, D′, and D², &c., and pipes, E, E′, and E² leading from the top of one water chamber to the bottom of another, a water supply pipe leading into the water chamber adjacent to the stack, and an outlet pipe leading from the water chamber nearest the inlet end of said flues, said parts being combined substantially as described.

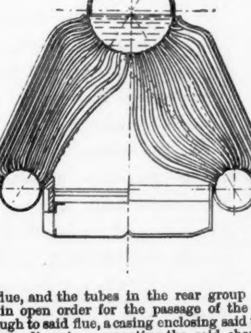


525,551

**525,614.** Steam Boiler, *A. Normand, Havre, France.—Filed March 15th*, 1894.

*Claim.*—In a steam generator, the combination with an upper chamber and lower chambers, of two or more groups of curved pipes of small diameter connecting said chambers and arranged in the form of an arch, the innermost and outermost tubes of the group over the grate being arranged in close juxtaposition to form a return flue, and the tubes in the rear group being arranged in open order for the passage of the gases therethrough to said flue, a casing enclosing said tubes, flues of large diameter connecting the said chambers outside of the casing, a smoke flue communicating with the return flue near the front of the generator, a smoke box connecting the return flue and the combustion chamber, and an inverted bridge M for diverting a portion of the products of combustion into said smoke box, substantially as described.

525,614



Throat Irritation and Cough.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. In contact with the glands at the moment they are excited by the act of sucking, the Glycerine in these agreeable confections becomes actively healing. Sold only in boxes, 7½d.; tins, 1s. 1½d., labelled, "James Epps and Co., Homœopathic Chemists, London."

## ENGLISH AND FRENCH QUICK-FIRE ARMAMENTS.

Public attention has been called to the fact that the French have succeeded in equipping their fleet with quick-fire guns with great rapidity. It has further been stated that the French fleet is now far ahead of us in this class of equipment in the Mediterranean, and it is hinted that although matters are better if we consider the Channel fleet, we are now behind them, and that they have reversed the relative position in which our fleet stood in this matter. It may be interesting to our readers to see how this question stands, as shown by "Brassey's Annual" of the present year.

First, as to actual numbers. We have taken ships "building," as well as those completed, but have excluded ships only "projected" and not commenced. This gives us the following figures:—British ships, total number armoured, 80; unarmoured, 208. French armoured, 63; unarmoured 99. The quick-fire guns for these are,

*British Armoured.*

If these quick-fire guns be considered irrespective of their calibre, it will be seen that the average number per armoured ship is, for England 15·5, against 10·3 for France; and for unarmoured 7·5 for England, as compared with 6·9 for France; but it may be seen that in the armoured ships France has a great prepondrance of heavier and more powerful quick-fire pieces, having in fact 258, against 213 of the English, and those of heavier metal, for we have included the 12-pounder among the English pieces. This gives 2·66 for heavy quick-fire guns per English armoured ship, and 4·1 per French armoured ship. On the other hand, England is stronger in her unarmoured vessel armaments, these having 617 heavier quick-fire pieces, as compared with 279 French, which makes 2·96 per English unarmoured ship, and 2·81 per French unarmoured ship. Thus France has an absolute advantage in one respect, that is in heavy quick-fire guns in the equipment of her armoured ships, while she is inferior in the total number of quick-fire guns of all calibres per ship in her armoured fleet, and in her unarmoured fleet she is slightly inferior both in the heavier quick-fire pieces and in total numbers. When we take into account the fact that we have to deal with 288 ships of all kinds, France with only 162, involving a total of 2802 pieces as compared with 1339, it will be seen that it could not with any justice be said that France is in advance of us in the work of supply if bare numbers only be considered. A mere statement of numbers may, however, be misleading. We have included many ships which are small and obsolete, which would only receive quick-fire guns under special circumstances, and, on the other hand, ships under construction. Both these may affect the results unfairly. The obsolete ships, which naturally have not been well supplied, may pull down the average, and the nation that builds its ships more slowly therefore has more in hand in proportion to her rate of turn out, benefits unfairly by reckoning ships building, yet it seems desirable to take some total number that has been arrived at without reference to our immediate object and on good authority, in order to be clear of bias. It must be understood, however, that our vessels going into action would naturally be so far selected that they would have a much larger number of guns than this average. To pass on next to the character of the pieces. Our own heavier guns are of the Elswick types, with light Hotchkiss 6 and 3-pounders and Nordenfeldt 6-pounders. The French pieces consist in a great measure of converted guns, the remainder being new pieces, chiefly those of Canet. The French converted guns have certain distinct disadvantages, both in being of older type and inferior power to the new pieces, and also in power of quick-fire. The Canet guns are excellent, but there is no justification for the recent attack made on our Elswick pieces in the press. We have brought quick-fire guns to conform to the conditions of service before our neighbours. If a lower rate of fire is claimed for our guns, we believe it will generally be found to be due to the fact that our guns performing at sea under service conditions are compared with continental guns firing on a practice ground.

It may be instructive to compare the case of sample vessels of about the same displacement and date. The Centurion, of 10,500 tons, completed in 1893, carries ten 4·7in., eight 6-pounder, and twelve 3-pounder guns. The Brennus, of 11,000 tons, launched in 1891, carries ten 16 cm., four 6·5 cm., and eight 4·7 cm. guns. The French ship with rather more displacement has a decided advantage in weight of metal, but fewer light pieces. The Royal Sovereign, of 14,260 tons, completed in 1892, carries ten 6in., sixteen 6-pounder, and twelve 3-pounder quick-fire guns. As there is but little difference between the 16 c.m. and 6in. guns, this equipment is decidedly more formidable than that of the Brennus; but the vessel is much larger.

The Charles Martel—building—11,882 tons, is to carry eight 14 c.m., four 6·5 c.m., twelve 4·7 c.m., and eight 3·7 c.m. guns. She is therefore less powerful in weight of metal than the Brennus, but has more light guns. Her quick-fire is decidedly inferior to that of the Royal Sovereign. Let us now turn to useful vessels of obsolete type. Our Dreadnought, 10,820 tons, completed in 1875, carries only six 6-pounder and twelve 3-pounder quick-fire guns. The French Duperré, 10,487 tons, launched in 1879, carries eleven quick-fire guns of unregistered calibre—probably light and not yet supplied, and not included in our tables above. Probably these will be of heavier metal than the Dreadnought's 6 and 3-pounders; but it is hardly fair to say much of guns not yet supplied, as we cannot but suppose that the Dreadnought may receive heavier quick-fire guns bye-and-bye. The French Devastation, 9639 tons, launched in 1879, carries only two quick-fire guns, calibre not given. Our own Devastation, 9330 tons, completed in 1873, carries six 6-pounder and eight 3-pounder quick-fire guns. In this instance our vessel, much older and smaller than the Frenchman, is the better equipped.

Passing to unarmoured ships, the Thames, 4050 tons, completed in 1885, carries three 6-pounder and eight 3-pounder quick-fire guns. The Sybille, 3400 tons, completed in 1890, carries six 4·7in., eight 6-pounder, and one 3-pounder quick-fire gun. These are the vessels most nearly comparable perhaps with the French Cecile, 5766 tons, launched in 1888, which carries six 4·7 c.m. quick-fire guns only. Our first-class cruisers of 9000 tons are too large to compare with the French, our second-class too small. The Brilliant may be taken as a representative modern second-class cruiser, 3600 tons, launched in 1891. She carries two 6in., six 4·7in., eight six-pounder, one three-pounder quick-fire guns. It will be seen, then, that our unarmoured ships more than hold their own well; they are superior to the French in quick fire.

On the whole our readers will probably concur with us in concluding from the foregoing figures, that France has by no means overtaken us yet in the matter of quick-fire equipments; nevertheless we think that good work has been done in calling attention to the rapid strides that she has made, enabling her to compare as well as she does with us, seeing what a start we had of her.

## WIND PRESSURE.

There can be but little doubt that it was owing to the deplorable disaster which resulted in the collapse of a portion of the Tay Bridge, with its attendant lamentable consequences, that engineers felt themselves obliged to examine theoretically and practically, and more closely than they had previously done, the phenomena associated with the action of the wind. It is not that the force, the violence, the impactive and the concussive effect of winds varying both in velocity and pressure upon bridges, roofs, chimneys, and, in fact, all engineering and architectural structures exposed to its fury, were not previously recognised by scientific and technical writers, and even some allowance made for them by their designers; but the whole question, which is exceedingly important, had certainly not received that attention and consideration which it unquestionably both deserves and demands. Engineers were accustomed to regard its effects in the light of perhaps possible but barely probable contingencies, which in the majority of instances were too remote and uncertain to be included as a factor in the calculations. It must be admitted that at that time there was a great paucity of real information; that is, of information of a character which would permit of trustworthy deductions being made, and upon which could be based mathematical analyses and investigations resulting in tangible and workable conclusions. At the present time, notwithstanding the value of the evidence afforded by the construction of the Forth Bridge, there is a great deficiency in the experimental data connected with the subject; although now sad experience has amply demonstrated that what were formerly considered as possible, or extremely improbable occurrences, have passed into the category of those which have actually happened. For years past most valuable and interesting meteorological observations have been undertaken and accurately recorded, both in our own and other countries, which constitute a mass of highly useful data. From these, in conjunction with other known facts, the relation between the velocity and pressure of the wind has been ascertained with a precision and fidelity which does not admit of controversy. But while establishing this generally received relation, the exact values of the coefficients are left undetermined. As a proof of the large amount of uncertainty which even now besets the calculations attending the pressure of the wind upon a surface obstructing its motion, let us notice the terms employed. In the first place, selecting a roof for example, the wind is "assumed" to blow horizontally. By another assumption, which neglects one of the components—which, though undoubtedly very small, yet exists—into which the horizontal pressure is resolved, a supposed normal pressure is produced upon the surface of the roof. If the amount of the horizontal pressure could be accurately ascertained for each separate instance, the problem would be very fairly solved, at any rate so far as practical requirements were concerned. But this is exactly where the necessary data are incomplete and indeterminate, so that another assumption has to be made, which may vary between the somewhat wide limits of 9 lb. and 93 lb. per square foot.

The complete immunity which the Menai tubular bridge—a form of structure opposing the maximum amount of resistance to the force of the wind—enjoyed both during its construction and erection, when it was in a condition of obvious unpreparedness, and when it was completed, probably led to the pressure of the wind being underrated. The introduction of the open web or lattice girders about this time, which gave their *congé* to the tubular system for ever, and also to the solid-sided girder for future large spans, conduced to accentuate the same idea of false security. It was fairly, and not illogically, argued something after this fashion: Experience has shown—recent experience—that a hollow wrought iron box, into the interior of which—and this is a feature to which we shall subsequently draw attention—the wind cannot find access, has withstood with perfect impunity, and without the presence of any especial precautions, the whole force and violence of the wind-currents, gusts, eddies, and storms which proverbially sweep through Straits of the contracted dimensions characterising the channel separating the island of Anglesey from the main land. Such being the facts of the case, the erection of open-sided girders in similar, and even in more exposed situations, should be attended with a still greater margin risk, on the supposition that any risk was admitted by the engineer of the bridge alluded to. As a matter now of professional history, Stephenson attached little or no importance to the action of the wind on his great tubes, and there is no doubt that he has been fully justified in the opinions he entertained. It is not so much the application of a single sudden impactive force upon a structure that is to be feared, as the isochronous repetition of it; and the observations which the engineer made while building his bridge, caused him to arrive at the conclusion that there was no evidence of isochronism in the erratic and fitful blasts that at one time threatened his great design. During one of the heaviest gales which had ever been known, while one of the tubes was supported solely on some loose balks, at an elevation of over 100ft. above sea level, the lateral deviation scarcely exceeded one inch, although, so long as the storm prevailed, it was impossible for any one of the workmen to maintain himself on the top of the tube without holding on. The pressure of a hurricane, at the period when the Menai tubular bridge was erected, was estimated at about 46 lb. to the square foot, which would amount in the aggregate to 280 tons on each tube. It is worth noticing that the *vis inertia*, or the insistent weight of the tube itself before it became united to its fellows, was calculated to be adequate to resist this force of impact, and the result confirmed the truth of the calculations. It is clear that the oscillations of a tubular, or of any other type of girder, would depend first of all upon whether the action of the wind currents was isochronously repeated, and secondly, whether they would coincide with the structural vibrations set up. In the latter event the result might be very serious, and if unchecked, would probably entail the downfall of the bridge. Fortunately there is no good evidence to support this supposition, that the two antagonistic forces might act in combination, so that all apprehension of danger from this source may be put aside. This coincidence in the separate and distinct vibrations being avoided, it is satisfactory to know that with respect to the Britannia tubes, "the heaviest gales do not produce so much motion as ten men."

When a wind wave encounters an obstacle in its course there is more than one mode of action open to it. It may sweep the impediment bodily away, literally annihilate it, as is the manner of hurricanes, and then pursue its tempestuous career in search of another victim. It may push it with more or less violence out of its path, as occurs when it urges on the swelling canvas of the ship, or turns the sails of the windmill. Again, should the obstacle prove too strong to yield to either of these attacks, the wave of air will be broken up into two or more currents, and—according to the nature of the obstruction—will pass over, under, through, or around it, until it finds one or more avenues of discharge. Before, however, the wave is able to adapt itself to perhaps the only avenue or path for escape available, it may be caused to deflect or to rebound from the surface exposed to it, although eventually it must get free. When the wind impinges against a long high wall, which it is powerless to remove, it is in the first instance made to recoil or rebound from the surface exposed to it, split up into numberless eddies, currents, fitful blasts and gusts, which drive here, there, and everywhere, until rising upwards—for they cannot go downwards—they mingle with the upper strata and regain their original conformation, impetus, and direction. That wind waves are thus deflected and diverted from their original course by the resistance of exposed surfaces is evident from what occurred at the Britannia Bridge, where a heavy gale was diverted from its horizontal course, and descending in an oblique direction, ploughed up the surface of the water below in clouds of spray for some distance from the tubes. It is impossible, with the incomplete and limited amount of data at our command, to arrive at any sound solution of many of the difficult and complicated questions regarding the actual pressure of the wind on railway bridges and other structures. Under what circumstances the maximum pressure would obtain depends upon so many conditions, so varied in character, that even an approximate answer cannot be put forward with any amount of confidence. The manner in which the wind wave is affected by the surface against which it strikes exercises a considerable influence upon its future force and behaviour. Sir Benjamin Baker remarks as follows, with respect to some of the valuable and interesting experiments carried out by him during the construction of the Forth Bridge:—"As a matter of fact, so far as my experiments extend, it would seem that the eddies caused by the front surface extend to a great distance in all directions, and in a complex structure the innumerable and conflicting eddies would almost appear to neutralise each other as regards some of the sheltered surfaces." It would be unwise to make any allowance practically for this neutralisation, as frequently the very contrary action takes place. The separate and distinct currents formed by the interposition of an immovable surface to the natural path of a wind wave, in their attempts to find an outlet, very often re-combine, and aided by continuous reinforcements, ultimately assume a condition analogous to that of an accumulated head of water. It is well known that tremendous local pressures are produced from this cause, and it is possible that the unknown maximum may be yet found under these conditions, though they are fortunately more exceptional than general.

There is another point in connection with the subject of our article which is also enveloped in the same mystery and uncertainty surrounding the whole question. What is the law, if any, which determines the relation between the pressures and the altitude of the wind—for it is certain that no one pressure is constant for all degrees of altitude? The authority we have quoted assigns a different value to the wind pressure at the high level of the lattice top member, and at the level of the bottom tubes of the Forth Bridge. Assuming the rule of the Board of Trade, that a pressure of 56 lb. per square inch must be allowed by engineers in designing their bridges, it may be asked, Is this pressure calculated as being the most appropriate and exact for any particular height above sea-level or ground line, or other selected datum; is it to be regarded as a kind of general average, or the absolute permissible minimum for all elevations? If this limit be correct for an altitude of between 150ft. and 200ft., the equivalent pressure at the level of an ordinary road bridge would barely amount to 20 lb. per same unit of surface, an item too insignificant to be taken into calculation. This established standard, arbitrary as it is, of the wind pressure, while no doubt, similar to all the rules of the same authority, framed for the safety of the general public, is frequently adopted by local authorities, and insisted upon in instances where a dispensation, or what might be fairly termed a suspension of the standing orders, would be freely accorded. In The Engineer of November 3rd of last year we drew attention, in commenting upon an open competition for a bridge over a navigable canal, to the manifest incongruity of specifying in the list of instructions to competitors that a wind pressure was to be allowed for of exactly the same amount as was adopted in the design of the Forth Bridge. In other words, the pressure of the wind was assumed to be identical at the summit of the Inch Garvie pier and at the level of a bridge at a height of a few feet over mean sea level. We have noticed the same preposterous stipulations stringently enforced in the case of small road and street bridges, and in other examples, where the structure is situated literally *à fleur de terre* or *à d'eau*, as the location might assign. Some more discrimination should be observed in apportioning, not only this excessive unit pressure, but also as regards other barely possible exceptional concentrated loads. It would not be a matter of surprise to us if competitive designs were invited for a bridge, to be erected in a mine some thousand feet deep, to find that a wind pressure of 56 lb. per square foot was rigorously insisted upon.

We have not space to do more than allude to one or two other interesting features respecting wind waves. In a "through" bridge of the open web type, with an open platform, it was, until recently, not unreasonably assumed that the windward girder bore the whole brunt of the wind force, and that but very little, if any, took effect upon the girder to leeward. It is evident that in the case of a plate girder, if the platform be solid, the conditions approach more nearly to those characterising the tubular system. The report of the "Wind Committee" was to the effect that a front plate girder gave complete shelter to its fellow to leeward. This conclusion is not borne out by actual experience unless the two girders are very close together—much closer than obtains in ordinary bridges. The degree of protection or shelter afforded by the front girder to the other will depend, *cæteris paribus*, upon the description of bridge, whether open or solid sided, the depth of the girders, their distance apart—and this is a very important detail—and the nature and position of the platform. The idea once entertained, that one bar in the web of a lattice girder would shelter its neighbour in the rear, has been renounced as untenable. Wind or air is a perfect fluid, and essentially a live or moving force, and from the earliest days of the application of cast and wrought iron to railway bridges, the efficacy of opposing deadweight to the *vis viva* or impactive violence of moving loads has been recognised too universally to admit of dispute. Without for an instant advocating the employment—as was by no means uncommon in the days just referred to—of factitious dead loading, yet there is no doubt whatever that the security and stability of a railway bridge, or, in fact, of any structure subjected to the action of violent live loads, is in the ratio, though not necessarily direct, which exists between the insistent or dead and the live or moving load. Paradoxical as it may appear, the dead load kills the live.

## HARBOURS AND WATERWAYS.

*The Mersey.*—The Marine Committee of the Mersey Docks and Harbour Board have advised that tenders be asked for the construction of a second dredger of similar capacity to the Brancker, and capable of holding 3000 tons. The chairman, in bringing this matter before the Board, stated that the quantity of sand removed from the bar up to the present time was 8½ million tons, of which the Brancker had removed 4¾ millions. The depth attained over the whole length of the bar, and over a width of 1600ft., is on an average 23ft. at low water spring tides. There are, however, places where the depth is only 20ft., and this at present constitutes the navigable depth. It is considered that a depth has now been reached when the two smaller dredgers which have been acting with the Brancker can no longer work advantageously. Latterly the progress of removal has been at a slower rate than it was formerly. This is due to the fact that the particles of the sand now raised are much finer, and the material also being of a more mixed quality takes longer to settle in the hoppers. At the depth of 20ft. the Brancker could raise 3000 tons in forty-five minutes, whereas at the present time it takes from two and a-half to three hours to load the same quantity. The cost of removing the sand by the Brancker is only about half that by the smaller dredgers. In point of economy, therefore, it is advantageous to work only with large dredgers and to withdraw the smaller ones. It is estimated that within twelve months after the proposed second large dredger is procured a minimum depth of 26ft. will be attained over a width of 2000ft. It is the general opinion that the expenditure of the £58,000 which the Brancker cost has been fully justified by the results obtained, and that with the aid of a second dredger such a depth throughout the entrance and channel of the Mersey will be permanently secured as will allow the largest American liners to navigate the river at all states of the tide. It is also proposed to spend £400,000 in carrying out an extensive system of lairages for the landing and reception of foreign cattle on land northward of the Alfred Dock at Seacombe, including slaughter-houses, chill-room, and a floating landing stage 1000ft. in length. The present lairages can accommodate 3200 animals, those proposed will be arranged to hold 18,500 head of cattle in addition to reception lairs for 2500 others. While thus cattle are to receive the most extensive and luxurious accommodation, it is hard that no provision is proposed for the comfort and convenience of passengers using the large American and colonial liners. Embarking from Liverpool involves the discomfort of being conveyed in a tender, or else enduring nearly an hour's ride in a cab from the railway station to the docks, over perhaps the roughest pavement to be found in any town in England, and then a delay of about the same time while the steamer is warped round the numerous turnings and locks which have to be encountered from her berth to the Mersey. On coming home the unfortunate passenger has, perhaps in a pouring rain, to get from the steamer on to a small tender where saloon and steerage passengers are all mixed together, and to wait patiently while the luggage is transferred from the steamer to the tender, an operation which consumes a considerable amount of time; then there is the transfer of passengers and luggage to Prince's landing stage, and the removal thence to the Custom House. It ought not to be a work of very great difficulty to provide a deep water berth alongside the landing stage, and to bring the train on to this, as is the case at Southampton and Dover. If something is not done to provide better accommodation for passengers, Liverpool may certainly expect to find Southampton become the favourite port of embarkation.

*The Tyne.*—The new deep-water entrance to the Tyne Dock has been completed and opened for traffic. This work was undertaken by the North-Eastern Railway Company, the owners of the dock, about three years ago, after a vigorous agitation by the shipowners and merchants using the dock, its progress having been delayed longer than was anticipated owing to unforeseen difficulties. For several years it has been necessary for large vessels loading in the Tyne Dock to take in only so much coal as would enable them to get over the sill and complete their cargoes in the river, entailing loss of time and expense. The new entrance removes this drawback to the usefulness of the dock, and there is now sufficient water over the sill to float out large vessels at neap tides. With the recent addition of the Dunston coal staiths and the new deep-water entrance to the Tyne Dock, the Tyne can now claim to afford adequate facilities for the loading of coal, which will enable the district to maintain its hold upon the trade which has so long been connected with the Tyne ports. The Tyne Dock was constructed for the North-Eastern Company, under the direction of the late Mr. T. E. Harrison, their engineer, and was opened for traffic in 1859. It is 55 acres in extent, and has boasted of being the largest coal shipping dock in the world. The shipments of coal and coke from this dock have risen from about 1½ million tons in 1860 to over 6 millions last year. The sailing vessels which formed a large part of the coal fleet in former days are now almost entirely superseded by steamers, and, while the total number of vessels has decreased, the tonnage and size of each vessel has considerably increased. The provision of improved facilities for landing coal commenced five years ago, when a contract was let to Mr. John Jackson for the erection of staiths for eight additional coal spouts, making in all thirty-eight spouts. The new staiths are fixed 10ft. higher than those already in use. The railway sidings were at the same time considerably extended. The sum expended on these works amounted to £70,000. Following on this, and acting under the advice of Mr. Wolfe Barry, a deeper entrance has been made, and the dock and approaches deepened by dredging. This work has been carried out by Messrs. Lucas and Aird. The new entrance is 70ft. wide, and has 27ft. of water at neap tides and 32ft at springs. There are now three entrances—the new lock on the west; the old central lock having a width of 80ft., but with only 22ft. on the sill at springs; and the eastern lock 60ft. wide, and capable of locking a vessel 300ft. long. The gates of the new lock are worked by the direct action of a hydraulic ram, chains being dispensed with. Although coal forms the chief shipment, there are other trades carried on in this dock, the imports consisting of iron ore from Bilbao, and grain, for the storage of which two large warehouses have been erected.

*The Humber.*—As already referred to in previous notices, the condition of the Humber has recently excited considerable attention. The alleged shoaling which is said to have taken place appears to have affected the local newspapers and landsmen more than the Conservators, the pilots, and the captains of the boats using the river. However, the agitation has been sufficient to attract the attention of the Corporation of Hull, who passed a resolution calling on a committee to ask the Conservancy to put into force the powers vested in them by the Ouse Lower Improvement Act of 1884 for the protection of the river. The powers here referred to relate to the improvements carried out by the Aire and Calder Navigation Company in training the river from Goole downwards, by which a very great improvement in the navigation of the river has been effected. There is, however, a clause in the Ouse Improvement Act to the effect that if as the result of these works any damage or impediment should arise to the navigation of the Humber, the Humber Conservators are authorised to require the undertakers to removes the damage and restore the river to its normal state, the question as to whether any such damage had occurred being left to the determination of the Board of Trade. From the proceedings at the meeting of the Corporation, and also at a subsequent meeting of the Pilotage Commissioners, it would appear that an entirely false alarm had been raised. It was stated on the authority of Captain Perry, of her Majesty's surveying ship Triton, which is engaged in a new survey of the river, that the navigable channels were never in a better condition than at the present time. There is a permanent depth of 35ft. in Hull Roads over a sufficient width for vessels to swing. Captain Hume, the chief conservator of the river, also confirmed this, and said the channels were as deep as they were fifty years ago. The general opinion of the pilots appears to be that the river has improved during the last few years, and that the water is now deeper than formerly, a statement borne out by the fact that the steamers going to and from Goole never attempted formerly to come down the river drawing more than 12ft., but that now they load down to 16ft. The scare originated by the removal of H.M.S. Edinburgh, which has been lying in the same berth near the Middle Sand for several years. Owing to some alterations in these sands, it was found that there was not sufficient room for her to swing safely, and she was moved to another berth. Rumour says that she and the previous ships which have occupied this berth for a great number of years have caused the shoaling by the cinders, beef bones, and rubbish thrown overboard. The salvors of the steamer which was wrecked in the Ouse about three months ago do not appear to have been very successful in their endeavours to remove her, as she still lies in the same position as when run on the training wall. They are now blowing her to pieces with dynamite.

*The Bristol Channel ports.*—It is stated that an agreement has been settled between the Harbour Trust Committee of the Cardiff Corporation and Sir William Lewis for the acquisition of the Bute Docks on behalf of the proposed Cardiff Harbour Trust. The amount required, which includes the purchase of the Bute Docks and Glamorganshire Canal, also extensive royalties belonging to the Marquis of Bute, is £6,000,000. From this it would seem that the Cardiff Harbour Trust, if ever carried out, will be a very extensive undertaking, as it is proposed also to include both the Taff and Barry undertakings.

At Bristol the long-expected report of Mr. McCurrich, the dock engineer, has been made public. Mr. McCurrich does not consider that the same facilities for the large American liners can be given at Avonmouth as now exist at Southampton, as the construction of a low water pier, capable of taking vessels at all states of the tides, cannot be carried out at a reasonable cost. That it is practicable to construct works at Avonmouth to give facilities equal in character to those at Liverpool; that such facilities could be afforded by the construction of a lock and dock at a cost of £1,070,000. If a breakwater be added the cost would be £30,000 more; that it is practicable to dockise the river, and that the best scheme for this purpose would be by constructing an entrance lock on the Gloucester side of the river, a dam from this to the other side, with sluices at its extremity. The cost of these and other attendant works is estimated at £1,520,000, or, if a breakwater be added, £30,000 more. To this has also to be added £700,000 for additional accommodation at Bristol, and for sewage works and for floods, making the total cost of dockising 2¼ millions. Even if this scheme be carried out, provision would still have to be made for vessels of the largest class at Avonmouth. Although very guarded in his remarks, it is evident that Mr. McCurrich does not favour the scheme of dockisation. He admits that although practicable from an engineering point of view, the works would be very difficult to carry out and very costly; they would take much longer to execute than the other scheme; and that it would be a more difficult matter to get from Parliament the necessary powers. With regard to the effect of excluding the large volume of tidal water which now flows up the Avon on the deep-water channel at King Road, although he thinks that this would not lead to injury of the channel, he expresses the opinion that it would be a very difficult matter to convince the Admiralty that such would not be the case, and that very considerable opposition, backed by the opinion of engineers of eminence, would have to be encountered.

*The Thames.*—There is a very large export of chalk from the quarries at the lower part of the river, and this trade has recently considerably increased, especially the shipments to America. About four years ago the quarries at Northfleet, near Gravesend, which, with the adjacent land cover a considerable area, were purchased by Mr. Arthur Tolhurst. To meet the increasing size of the vessels which come for the chalk, he has recently constructed a deep-water pier which extends 240ft. into the river, and has a T-head 230ft. long and 32ft. wide. The railway lines laid down in the quarries are continued to the end of the pier, where the trucks discharge the chalk through shoots into the holds of the vessels. The front piles are 80ft. in length and 18in. square. The shorter piles are 12in. square, and all have been driven from 16ft. to 18ft. into the chalk, of which the river bed is composed, the approximate force required to drive them being about 50 tons. At the face of the pier the depth of water is 25ft. at low-water springs and 45ft. at high-water. The cost of the pier has been £10,000. Vessels of 5000 tons burden have been loaded at the pier since its completion.

Extensive alterations are about to be made at the Surrey Commercial Docks, principally for the purpose of meeting the increased requirements of the timber trade. This system includes sixteen different water areas, the docks covering 84½ acres, and ponds 71½ acres. There are four entrances from the Thames. About thirty years ago the Surrey Docks and Canal Company was united with the Commercial Docks, and for the purpose of improving the connection between the two systems the Canada Dock was constructed in 1876. Formerly the timber trade, of which the docks on the south side of the Thames have practically a monopoly, and which constitutes about 75 per cent. of the whole imports into these docks, was carried on in sailing vessels of small tonnage, but for the last twenty years these have been gradually giving place to steamers requiring a much greater depth of water. These timber steamers have to pass through the Surrey Lock, which is 250ft. long, 50ft. wide, with 28ft. on the sill at H.W.S.T. The South Lock, which is 220ft. long, 48ft. wide, with 28ft. on the sill, is principally used for ships carrying grain. The Greenland and Lavender Locks have only 18½ft. on the sills. The former, which was rebuilt in 1808, it is now proposed to reconstruct with a wider outlet to the Thames, and also to make a new canal lock to complete the junctions of the two systems commenced by the construction of the Canada Dock. Powers to carry out these works were obtained in the last session of Parliament, the amount authorised to be raised being £220,000. The plans for the alterations have been made by Mr. M'Connochie, the company's engineer.

The deepening of the Sault Ste. Marie Canal, on the Canadian side, is to be proceeded with, under a new loan of £500,000 just secured in England by Mr. Geo. E. Foster, the Canadian Minister of Finance.

## DE RECHTER'S RADIAL SUSPENSION FOR RAILWAY CARRIAGES AND TRAMCARS.

We illustrate above part of the under frame of a railway carriage exhibited at the Antwerp Exhibition by the Administration of the Belgian State Railways. The extreme length of the frame is 39ft. 9in., and the width 7ft. 4in. It is carried on three pairs of wheels, of which the axles of the outer pairs are articulated, on the system invented by Mr. F. De Rechter. In this system, which is applicable to vehicles with two or more pairs of wheels, the radial displacement of the end axles is obtained by means of separate frames or trucks, which carry the horn plates, and are supported by the suspension springs, which they serve to brace together. The latter, which are fixed to the oil boxes, carry the main frame of the carriage, just as in ordinary rolling stock.

The principle on which this new system of suspension is based, is founded on the fact that a heavy body suspended by two pairs of jointed rods will turn round an imaginary point, if a force is working on it, in a direction at right angles to the axis of the figure, formed by joining the points of suspension of these rods. Thus, the block L M N O—Fig. 1—suspended by the rods $a\ a^1$, $a\ a^1$, $b\ b^1$, $b\ b^1$, which are arranged symmetrically to the axis X Y, and of which each pair are of equal length, will turn round the point $c$, if a force F working at right angles to the axis X Y is applied at P. The position of this point $c$ is more or less that of the point K, which can be found by setting out the lines K $a$, K $b$, in which the distances K $a$, K $b$ are proportional to the lengths of the rods $a\ a^1\ b\ b^1$. And the heavier the block L M N O is, the more nearly will the two points coincide. It is evident that the number of suspension rods need not be limited to four, if only they all have lengths which are in proportion to the distances that separate them from the point K.

If, instead of applying the force F to the body L M N O itself, it is applied at $P^1$—see Fig. 2—the point where the two lines $a^1\,b^1$ intersect, and if we suppose L M N O to be immovable, but weighing on the rods, it is clear that the figure $a^1\,a^1\,b^1\,b^1$ will turn round the point $C^1$, whose position with regard to the four rods is similar to that of C, as described in Fig. 1. Now the above represents what takes place in a railway carriage, when it passes from a straight line to a curve. The heavy body L M N O represents the frame and upper part of the vehicle, the swing links of the springs are represented by the rods $a\,a^1$ and $b\,b^1$, whilst the figure $a^1\,a^1\,b^1\,b^1$ represents the whole rolling apparatus, *i.e.*, the pair of wheels, with axle, springs, &c.

When the vehicle passes from a straight line to a curve, it has always a tendency to take a tangential direction; whilst the wheel, coming against the edge of the outer rail, is driven back at right angles to this direction, towards the centre of the curve, and this is what constitutes the force F. We see, therefore, that to oblige the axle to take of its own accord a suitable position, when going round a curve, it is sufficient to make the links of unequal lengths, and of dimensions so proportioned that they shall cause the axle to pivot round a point suitably chosen on the longitudinal axis of the vehicle. This point should evidently not be too far from the axle, so that the end of the vehicle should not go too far outside the curve, and so that the axle should always be in a radial position to the curvature of the line, whatever this might happen to be. When the vehicle leaves the curve, to enter the straight part of the line, the force F will disappear, and the weight of the carriage will be sufficient to cause the axle to return to its normal position.

The springs are connected at one end to the main frame by vertical bridles, which terminate at the supports of the fixed links, and at the other by movable curved supports, which can roll on the gusset plates. The fixed supports are at the ends nearest to the gudgeons, whilst the curved movable supports, or "sectors," are at the other end. The gudgeons, as in the Bissel bogie, are in the longitudinal axis of the main frame. The draw-bars are hinged at a point near each gudgeon, so as to allow of horizontal angular displacement. They pass through mortices in the cross pieces of the truck frame, and follow all the movements of the latter with regard to the main frame. The brake apparatus is so arranged that the blocks move sideways with the wheels, the point of application of the brake power for each truck being close to the pivot of that truck. Thus the angular movement of the wheel axles is not hampered by the action of the brakes.

The bridles of the links which join the fixed supports to the ends of the suspension springs turn on rollers, as also do the bridles which are connected with the sectors, and which correspond to the ends of the springs the furthest removed from the gudgeons. The gusset plates have ribs on them to guide the sectors, and these ribs are placed at right angles to the line joining the centre of the gudgeon with the centre of the eye of the spring—see dotted line on plan, Fig. 4. These gussets also serve to connect the intermediary cross-pieces with the longitudinals of the main frame. The curve of the sectors is struck from a centre situated below that of the bolt, which passes through the the roller of the suspension bridle. This excentricity will, by the weight of the carriage itself, tend to bring back the springs, and consequently the truck frames, into their normal positions. The inclination which the bridles of the fixed supports take, when going round a curve, will also have the same tendency. Stops are placed on the sides of the sectors; these enter slots on the ribs which are on the gusset plates, and prevent the sectors from going over too far on either side. Fig. 3 shows the elevation of one end of the carriage frame, and Fig. 4 is the plan of the same. Fig. 5 is a half end elevation, and Fig. 6 a half section, taken through the axle. Fig. 7 is a section through the main frame outside the truck, and showing the pivoting arrangement.

When the truck needs repairing, it is only necessary to remove the gudgeon, disconnect the end of the draw-bar, and unbolt the gusset plates; when the main frame can be lifted from the trucks, so that they can be repaired, or replaced by others in good order. If it is merely requisite to take out the wheels, it is sufficient to take off the lower caps and to lift the main frame, the same as with any ordinary railway carriage. The trucks would remain attached to the main frame, and the pair of wheels with their axle would be left on the rails.

Another exhibit at Antwerp is a platform car, which is also fitted with De Rechter's radial suspension. It is shown by Messrs. Ragheno and Co., of Mechlin. The length of the platform is 34ft., and the width 8ft. It stands on two bogie trucks, and has steel tubes, instead of girders or channel irons, for the side frames. It is loaded with bricks, which, according to a certificate signed by the engineer of the machinery hall, weigh forty tons. In several points of detail this car differs from the one shown by the Administration of the Belgian State Railways: but the long and short link, as shown on Fig. 3, and the rest of the pivoting arrangements are similar.

When used for tramcars, or narrow gauge railways, the system has to be modified. On a main line railway, where the radius of the curves is usually not less than 220 yards, and where the floor of the carriage is sufficiently high above the rails, there is nothing to prevent the links being made of suitable lengths. But with narrow gauge railway carriages, or tramcars, the wheels being of small diameter, brings the platform nearer to the rails, and the curves being usually much sharper than on main lines, it would not be possible to make the links of the proportions that would be required. For this reason, Messrs. Botey and Moreau, of Brussels, who exhibit the under frame of a metre gauge carriage, have introduced the modifications shown in Figs. 8, 9, and 10. Instead of the large links, curved rubbing pieces—P, Figs. 8 and 10—have been substituted and have the same effect. The suspension springs thus form part of a movable frame, which carries the horn-plates, and is connected with the main frame on the one side by the two short links, and on the other side by the rubbing pieces, which take the place of the long links. The truck frame also carries the draw-bar and pivots round a vertical gudgeon fixed to the main frame at the imaginary point of rotation, as described above. This gudgeon is shown at C, and the short links at M, whilst Q represents the frame of the truck.

We are indebted for the drawing, from which Figs. 3 to 7 have been prepared, and for most of the information given in the above description, to M. Léon Bika, M. Inst. M.E., general inspector and chief engineer of the Belgian State Railways.

## PEKING.

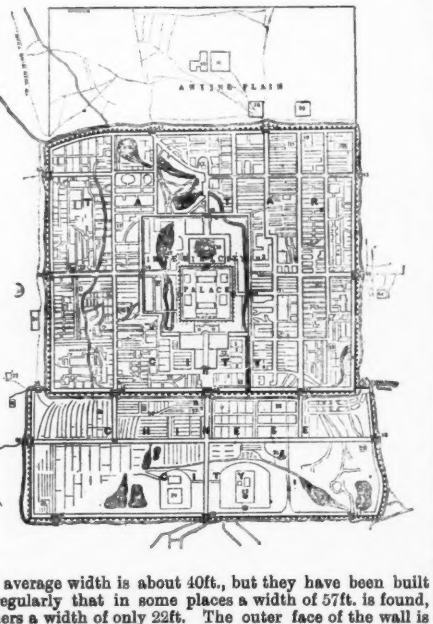
INASMUCH as the capital city of China will probably play an important part in the very near future, some information concerning it will be acceptable, we think, to our readers.

By far the most striking approach to the capital of China is that by the Tung-chow paved way. A fine high road of some hundred yards in width extends for two miles outside the city walls, its sides lined with respectable-looking shops, and in a state of cleanliness which contrasts favourably with most of the roads in the neighbourhood. Peking is situated in a sandy plain about thirteen miles N.W. of the river Peiho, and 110 miles W.N.W. from its mouth. A canal called the Yun-liang-ho runs from under the city walls to Tung-chow, where it enters the Peiho.

The city formerly existing on the site of the southern portion of Peking was the capital of the Kingdom of Yen, about 222 B.C. This kingdom was overthrown by the Tsin dynasty, and the seat of government was removed elsewhere. The court was restored to Peking by the fourth sovereign of the Kin dynasty in 1151, and named the celestial residence. In 1215 it was captured by Genghis Khan. In 1264 Kublai Khan fixed his residence there, the city being transferred one mile to the north of its former site. Thus the old portion became what is now known as the "Chinese city," and the terms "northern" and "southern" city, or more commonly nei-ching—within the walls—and wai-ching—without the walls—came into use. Under the native emperors who succeeded the Mongol dynasty, the court was removed to Nanking, which was considered the chief city of the empire, until, in 1421, Yung Lo, the third emperor of the Ming dynasty, again removed the seat of government to Peking, since which date it has remained the capital of China. Under the Mongols the city was called Khanpalik—corrupted into Cambalu: hence the name given to it by Marco Polo and early writers. The Tartars call it Pei-King-Cheng—northern, royal, residence, but generally omit the "Pei."

Peking was at first surrounded by a single wall pierced with nine gates. A part of the southern portion was subsequently enclosed, and the city now consists of two portions—the northern or Tartar city, and the southern or Chinese. The former contains about twelve square miles of ground, and in it are situated the palace, the Government buildings and barracks for the troops. The southern city is inhabited almost exclusively by Chinese. At the time of the Manchu conquest, all their officers were billeted in good houses within the inner city, but the wily Mongols have, in the course of time, got possession of them again, and Northern Peking is now largely tenanted by them.

The walls of the Tartar city are of an average height of 50ft., but portions of the north wall reach the height of 61ft. Their average width is about 40ft., but they have been built so irregularly that in some places a width of 57ft. is found, in others a width of only 22ft. The outer face of the wall is perpendicular, whilst its inner face slopes, in some places very considerably. Parapets are erected on both inner and outer faces of the wall, that on the latter being loopholed and crenellated. At intervals of about fifty or sixty yards are large buttresses, every sixth being of much larger size than the others; the smaller ones are about 15ft. to 20ft. square. Part of the inner brick lining having fallen away from the north wall, an opportunity was afforded of observing its construction. Near the gates the walls are occasionally faced with stone, but in other parts by immense bricks which bear a strong resemblance to stone. The space between the facings is filled up, first by a solid foundation of concrete of some 10ft. in depth, then by a layer of well-rammed earth, another layer of concrete, and another of earth succeed, the latter being paved with large blocks of granite, which form the *terre-plein*. The earth to fill in the wall was taken from the ditch which surrounds the city. The concrete resisted all the efforts of our sappers to form a trench on the *terre-plein* during the last war. Each of the gates has a buttress on either side connected by a semicircular wall, which thus forms an *enceinte*. That of the central south gate is larger than any of the others, and is the only one with three entrances—the central gate being for the use of the Emperor or his family alone. The arches of the gateways are well built.



The wall surrounding the Chinese city, and joining the other at the eastern and western extremities of its south face, is about 30ft. in height, 25ft. thick at the base, and, owing to the great slope inwards, only about 15ft. wide at the *terre-plein*; it is parapeted and buttressed.

The Tartar city wall is $14\frac{1}{2}$ miles in circumference. From east to west its total length is $4\frac{1}{3}$ miles, and from north to south $3\frac{2}{3}$ miles. The circumference of the wall surrounding the Chinese city is nearly 14 miles, or 10 miles from its points of junction at the east and west ends of the Tartar city wall. The total girth of the two cities is therefore 20 miles. The Tartar city appears to be composed of three squares, one within the other. The innermost of these is the area containing the palace, called the "Nei-kung," and known as the "Prohibited City." The walls surrounding the palace grounds, which enclose a space of about a square mile, are built of red brick, and crenellated. The terraces and glacis are also of brick, while the walks within the enclosure are stone paved. The gate forming the outer barrier of the palace is situated in the south wall of the Imperial city. It is a low ugly building with three doors, so constructed as to be in accordance with the usual Chinese custom, that interior magnificence should in no way be indicated outside.

Further on is the Meridian Gate, which is the southern entrance of the prohibited city, and the second from the palace itself. Before this gate on the east is a solar, and on the west a lunar, dial. In the tower above it, called the Teng-wen-ku, is a large gong, which is said to have been used in the time of the Ming dynasty—in the same manner as the drums to be found at the entrances of magistrates' Ya-meens at the present day—by would-be petitioners who, having failed to obtain justice through the ordinary channels, were permitted, by striking it, to draw the attention of the Emperor himself to their grievances; death, however, being the penalty of a needless or frivolous appeal. At the present day it is struck when the Emperor passes through the gate.

Inside is a courtyard, through which runs a small canal, crossed by five bridges with carved balustrades, lions, &c., all in fine marble. Enclosed is a building called the Tai-ho-Tien, which has five avenues of fine marble like the bridges. It is upon a basement 20ft. high, and rises to a total elevation of 110ft. The ascent is by five flights of forty-two steps each, with balustrades, ornamented with tripods and other figures in bronze. The central avenue is very broad, and is used by the Emperor alone.

At the back of the Tai-ho-Tien is the gate leading to the palace proper, which consists of four large and two smaller buildings, the latter of which are allotted to the Dowager-Empress and suite. According to native descriptions, the palace used as the actual residence of the Emperor has its floors painted of a vermilion colour, disposed in a square pattern. The centres of the rooms are covered with native yellow velvet carpet, and in most of them the furniture is constructed of the best southern wood, which takes a high polish. They assert, however, that the Emperor's own room contains sofas, &c., of which the frames consist of solid gold. The official reception-room has a carpeting of rough velvet worked with yellow dragons, and it contains no seats, except the throne itself—none, however, high his rank, being permitted to assume any other than a kneeling position while in the presence of the sovereign. The throne itself is placed on an elevated dais 90ft. high, and ascended from behind by staircases. Beneath, and supporting it, is a large gilt copper dragon, with five claws. On either side of the hall is a music gallery. It was in this palace that Kanghi celebrated a singular festival in 1722, for all the men in the empire over sixty years old, that being the sixtieth year of his reign. His grandson, Kien-Lung, in 1785, in his fiftieth year of reigning, repeated the same ceremony, on which occasion the number of guests was about 3000. Beyond the Emperor's palace, stands the palace of "Earth's Repose," where the Empress, or "heaven's consort," rules her miniature court in the Imperial harem, and between which and the northern wall of the forbidden city is the Imperial flower garden. The gardens are adorned with pavilions, temples, and groves, and interspersed with canals, fountains, pools, and flower beds. Two groves, rising from the bosoms of small lakes, and another crowning the summit of an artificial mountain, add to the beauty of the scene.

In the eastern part of the prohibited city are the offices of the Cabinet and of the Imperial Treasury. To the north is the "Hall of Intense Thought," where sacrifices are presented to Confucius and other sages. Not far from this stands the Hall of the "Literary Abyss," or the library, the catalogue of whose contents is published from time to time, forming an admirable synopsis of Chinese literature. North of the Imperial Palace enclosure is a square walled space more than a mile and a-half in circuit. This contains the King-Shan, an artificial mountain, composed of coal brought long ago from the mines at Ping-Yang to the northward of the province. This remarkable mound is about 150ft. high, and is covered with earth, in which a number of trees are planted, which line the paths to the summit and border the base. The top, crowned with pavilions, presents a splendid view, whilst animals and birds in great numbers occupy and enliven the enclosure. The earth and stone to complete this mountain were taken from the ditches and pools dug in and around the city, and near the base are picturesque tanks, surrounded with trees and flowers, from which materials were also excavated.

The western part of the prohibited city is chiefly occupied by a park, in and around which are found some of the most beautiful objects and spots in Peking. An artificial lake, shown on the engraved plan, more than a mile long, and averaging a furlong in breadth, occupies the centre. It is supplied by the Tung-Hwui river, and its waters are adorned with the splendid lotus. A marble bridge of nine arches crosses it, and its banks are shaded with trees, beneath which are paved walks. Artificial hills of rockwork, and summer-houses on marble bridges in the midst of lovely gardens, are seen everywhere.

The next enclosure surrounding the prohibited city is the Imperial wall. This is built of brick, roofed with yellow varnished tiles, is some 25ft. high and about 6ft. in thickness. It has four gates. The walks within the Imperial city are wide and well kept, and afford a favourite ride to the foreign inhabitants, except during heavy rain, when they are almost impassable. The bridge before alluded to is the only public road for crossing the Imperial grounds. On the eastern bank of the lake is a large white pagoda, built in Indian style. It is said to have been erected on the rising ground where the last of the Ming Emperors, with the flames of his burning palace in view, hanged himself to avoid the degradation of falling alive into the hands of his conquerors. There will probably be within the next few months an opportunity for the last Manchu Tartar Emperor of China to perform a similar ceremony, in handing over the keys of his empire to the Japanese field-marshal Oyama, who appears at present to have every intention of occupying Peking.

We refrain from giving our readers a description of the many and interesting temples to be seen in Peking, but the Observatory in the Tartar city cannot be passed over. Near the eastern end of the south wall, looking north, we perceive at 500 yards distance a sort of square tower abutting on the inner face of the wall, and some 12ft. higher, which is the much-talked of observatory at Peking. This observatory, built by the Emperor Kanghi, and furnished with instruments constructed under the direction of Ricci and other

Roman Catholic missionaries—who at that time, in spite of all difficulties, had managed, not only to penetrate to the then hermetically-sealed capital of the middle kingdom, but to become the advisers and authorities of the Imperial Government upon all points of science—is a stone building of two stories, the lower one being now unused. The upper and exposed portion, which still retains the frameworks of the magnificent instruments originally placed there, is the chief point of interest. The courtyard contains two planispheres, each supported on cast bronze dragons of exquisite workmanship, inferior to nothing producible in Europe. The instruments on the summit consist of a celestial globe, on which are laid down all the principal stars visible in the latitude of Peking; various quadrants and other instruments for determining altitudes, and lastly a species of transit instrument, which appears to have been extensively made use of. The telescopes, glasses, &c., belonging to these have long since disappeared, having been appropriated by those in charge.

To the west of the observatory is the examination hall of the vast number of the literary candidates who resort to the State examinations. It contains an enormous number of cells—said by the Chinese to be 10,000—and in these, upon periodical occasions, may be seen students from the age of twenty-five to that of sixty, patiently plodding away at copies of the sayings of Confucius and Mencius, the test of handwriting being the most serious one in the whole synopsis.

The Chinese city is principally occupied with hotels, municipal buildings, temples, merchants' dwellings and shops. It is here that visitors usually stay whilst at Peking. The legations are mostly between the gate of the Imperial enclosure and the outer portion. The accompanying figures have reference to the map:—(1) British Legation. (2) German Legation. (3) Russian Legation. (4) French Legation. (5) United States Legation. (6, 7, 8) French Mission Churches. (9) Foreign Customs. (10) Lama Temple. (11) Confucian Temple. (12) Corean Embassy. (13) Mahomedan Mosque. (14) Observatory. (15) Imperial Temple. (16, 17) Temples. (18) King-Shan. (19) Examination Hall. (20) Russian Mission. (21) French Church Mission. (22) Mongol Market. (23, 24) Temples. (25) Golden Fish Ponds (26, 27) Picture Street and Theatre. (28) Book Street. (29) Foundling Hospital. (30) Hospital. (31, 32) Soup Kitchens. (33, 34, 35) Temples. (36) Graves for Criminals. (37) White Ming Pagoda. (38) Russian Cemetery. (39, 40, 41) Temples. (42) Drum Tower. (43 to 51) Gates of Tartar city. (52 to 55) Gates of the Imperial city. (56 to 62) Gates of the Chinese city, exclusive of wall dividing Chinese and Tartar cities. (64) Temple. (65) Execution Ground.

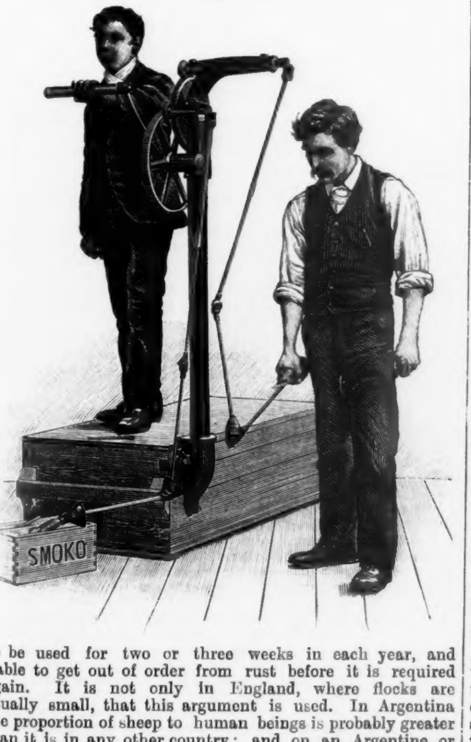
For much of our information, and for the sketch map, we are indebted to the "Treaty Ports of China and Japan," a work printed in Hong Kong, and to Dr. Williams' well-known works.

## THE NEWALL-CUNNINGHAM SHEEP SHEARING MACHINE.

A HAND-power double sheep-shearing machine, the invention of Mr. J. W. Newall, was shown at work on Tuesday, the 20th inst., at the Great Northern Horse Repository, Caledonian-road.

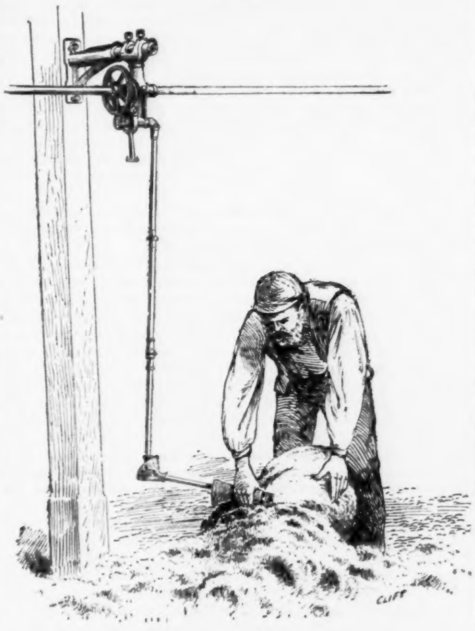
The use of sheep-shearing machines has been more general in Australia and New Zealand than in other parts of the world, and there is no doubt that with a machine which is well made, and kept in good order, shearing can be done more evenly than with shears, with less risk of injury to the sheep, and less fatigue to the operator. But as shearing is an operation which only takes place once a year, many farmers are not prepared to put up a line of shafting to be used for two or three weeks in each year, and liable to get out of order from rust before it is required again. It is not only in England, where flocks are usually small, that this argument is used. In Argentina the proportion of sheep to human beings is probably greater than it is in any other country; and on an Argentine or Uruguayan *estancia* sheep-shearing is the event of the year. There is no country where threshing and baling machines have come into more general use; and this is a proof that the farmers are not prejudiced against machinery. But though some of them have started sheep-shearing machines, they have not been adopted to any great extent. It may fairly be said, whether we consider the small flocks of England and France, or the gigantic ones of Australia and Argentina, the first requisite in a shearing machine is that it should be movable.

Fig 1



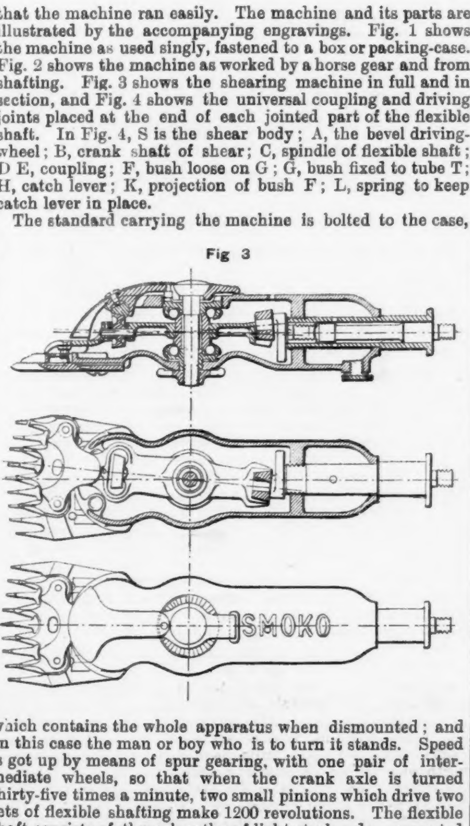
The next point is that of speed. There are authenticated instances in Australia of 200 sheep being clipped by one man in twelve hours, but ten per hour may be taken as a fair average. As the shearers are paid by the piece, they will not take kindly to any machine which does not enable them to clip a larger number than they could with shears. Mr. Newall estimates that a good shearer should be able to shear 130 sheep per day with his machine, as he says that they have frequently been sheared in 3½ to 4 minutes each by skilled men. On Tuesday six sheep were sheared, two at a time. The average for each was 8½ minutes, but the shearers were not endeavouring to make a time record; their object was rather to show the neatness with which the whole of the wool could be removed, including that on the head and legs. They were also slightly delayed by several of the gentlemen present, who wanted to turn the handle, to assure themselves that the machine ran easily. The machine and its parts are illustrated by the accompanying engravings. Fig. 1 shows the machine as used singly, fastened to a box or packing-case. Fig. 2 shows the machine as worked by a horse gear and from shafting. Fig. 3 shows the shearing machine in full and in section, and Fig. 4 shows the universal coupling and driving joints placed at the end of each jointed part of the flexible shaft. In Fig. 4, S is the shear body; A, the bevel driving-wheel; B, crank shaft of shear; C, spindle of flexible shaft; D E, coupling; F, bush loose on G; G, bush fixed to tube T; H, catch lever; K, projection of bush F; L, spring to keep catch lever in place.

Fig. 2



The standard carrying the machine is bolted to the case, which contains the whole apparatus when dismounted; and on this case the man or boy who is to turn it stands. Speed is got up by means of spur gearing, with one pair of intermediate wheels, so that when the crank axle is turned thirty-five times a minute, two small pinions which drive two sets of flexible shafting make 1200 revolutions. The flexible shaft consists of three lengths of light steel rods, connected together by swinging bevel gearing, and fixed in a jointed sheath made of steel tube. At the top of the sheath is a universal joint, which allows movement in any direction without interfering with the free running of the internal driving shaft; and at the lower end of the shaft another universal joint connects it to the clippers. The swinging bevel gearing, which is the invention of Mr. Newall, is one of the chief specialities of the machine. In this gearing the teeth have a curved sharp edge, terminating in a point, and they are bevelled in such a manner that they are always in contact at any angle. Consequently, whether the shaft is allowed to swing freely, or held straight, or in any position, the motion from the machine is transmitted uninterruptedly to the cutter.

Fig 3

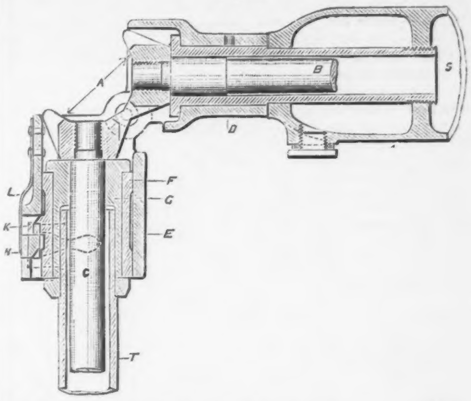


This has four teeth. It measures 1¾in. from point to point, or 2in. over all; and it works over a rounded steel comb 2½in. wide. The cutter pivots on a steel cap which runs on small steel balls, and the comb can either be held down so as to shear as closely as possible, or by distance pieces being fixed to the back of it, it can be arranged to leave all the wool of a certain length, say, half an inch or three-quarters. When once the date of shearing has been fixed, and the men engaged, it is impossible to postpone it; and it frequently happens in Scotland, and also in warmer localities, that if the sheep are sheared too closely, many of them are lost. Sheep-shearing machines would have succeeded better in Argentina if the first ones sent out had been provided with these guides.

It would be an interesting experiment to see how many sheep could be sheared in eight hours by two men and a boy with one of these machines, with the distance pieces set to leave half an inch of wool all over, and not trimming the heads and legs with that care which was displayed on Tuesday.

A useful modification of this machine would be one by which a number of them could be driven by steam, electricity, or horse-power, without the need of overhead shafting. At shearing time on a large estate there is work for every man or boy than can be had, without requiring one to set the clippers in motion for every two shearers. The machines run so easily, that it would be possible to join a number of them by a line of shafting running along their bases, and connected at each machine by universal joints, so that the floor of the shed would not need to be perfectly even. Of course this would only be advantageous where a number of shearers are employed, the hand-power machine now exhibited being all that most British farmers will require.

Fig. 4



## THE IRON GATES OF THE DANUBE.

By BELA VON GONDA, Chief of the Department of Navigation of the Interior.

(*Continued from page* 378)

BOTH dykes of the Iron Gate Canal are projected to be 0·5 metre high above the highest known water level. The dyke of the right side, being intended to serve also as a towage path, is to have a crown breadth of 6 metres, while the crown breadth of the left dyke is only 4 metres. The slope of both dykes on the canal side will be 1 : 1·25 towards the Danube, and 1 : 2 towards the shore. The bank of the left side of the canal leaning against the dyke as a foundation will be constructed of mixed gravel and earth, and on the canal side it will be covered with a stone pavement. The inner part of the dyke on the right side is constructed also out of mixed material, surrounded on both sides by corresponding strong stone dykes, the surface of which will be paved to protect it against water and ice.

As to the systematic deepening of the bottom of the Iron Gate Canal, it was arranged in the projects that after the construction of the left dyke to the rock bank Prigrada, the upper mouth of the canal being blocked by a corresponding stone dyke, the blasting of the rock necessary for the deepening of the canal should be executed by damming out the water, at least where it is shallow and quiet, as this will considerably diminish the costs of the works.

The works were begun in accordance with these proposals, and as the contractors succeeded in pumping the channel dry, and thereby facilitated the deepening of the canal in the rocky part, the present Hungarian Minister of Commerce, Mr. Bela Lukács, was induced to further increase the depth, in order to make the part of the Danube below the Iron Gate accessible to larger ships of 2000 to 2200 tons, drawing 2·5 to 2·75 metres, and to bring the great traffic of the Lower Danube in direct communication with the Black Sea, as far as Orsova, situated on the Hungarian frontier, and consequently creating a transit station connecting it with the lines of the Hungarian State Railways. For these reasons he determined to take advantage of the opportunities to construct the Iron Gate Canal 3 metres deep below the lowest water-mark, instead of 2 metres, and this, of course, caused the deepening of some of the shallow places of the Danube between the Iron Gate and Orsova. The velocity of the stream is calculated to be $\frac{4}{5}$ metre per second on the canal constructed in this manner, and the quantity of water per second at low-water mark to 2000 cubic metres, and at high water to 3000 cubic metres. Against this the quantity of the down running water in the channel at low water is 2000 cubic metres, just half of which has to be led into the Iron Gate Canal, so as to supply the calculated water depth.

In order to be able to form an idea of the size and extension of the works of construction of the Iron Gate Canal, we must mention that 367,000 cubic metres of rocks had to be blasted out of the bottom of the canal, and 297,000 cubic metres of stone laid and 270,000 cubic metres mixed material used for the construction of the dykes, besides the section of the lower and upper mouth, the final settlement of which will depend upon the modified state of the water and of the progress of the work.

The relative fall of the low-water surface on the Iron Gate Canal is calculated to 0·00249, which is especially at low water, considering the smoothness of the channel of the canal, being partly cut into the rocky bottom, partly amongst dykes covered with stones, is so considerable that it will give a water velocity of 4 to 5 metres, for the surmounting of which they will be obliged to establish a special towage service on the length of the canal, about which studies are already made. This towage will be such a one as to satisfy the greatest demands of the navigation on the Lower Danube.

It was impossible to avoid the above-mentioned extraordinary great fall of the canal, because by the difference of water surface of 4 to 5 metres prevailing in the channel above and below the Iron Gate, the water surface of the canal is a result of natural barriers, including the rock walls, which cannot be more favourably formed by an open canal.

The disadvantage resulting from the fall of water surface is, however, not so great as it would have been by the construction of a lock canal, which would have hindered the navigation in a larger measure—not considering the wear and tear of the lock, which would cause interruptions of the navigation for a longer or shorter time. For the removal of this—the most considerable hindrance to navigation on the Lower Danube—formed by the cataracts of the Iron Gate, the projected open canal, provided with an apparatus for the towage of ships, is to be regarded as the best solution of the question, and satisfies the greatest demands of modern navigation.

Thus, the cataracts of the Lower Danube will, by the above described improvements, become navigable. But among these cataracts—though spread over considerable length—there are shallow places, prominent rock peaks, which will be deepened, viz., blasted to 2 metres below the lowest water surface. For this purpose 10,000 cubic metres of rocks are to be blasted away under the water.

*Statement of Quantity of the Work to be executed to render the Iron Gate and the other Cataracts on the Lower Danube Navigable.*

The regulation works to be executed to render the cataracts of the Lower Danube navigable having been finally established, and the financial situation ameliorated, the Hungarian Government, viz., Gabriel Baross, the Minister of Public Works and Communications of that time, presented in 1888 to the Legislature the general projects and estimates of the regulation works necessary for the re-moval of the navigation hindrances existing at the Iron Gate and at the other cataracts. In consequence it was decided by the XXVI. Law of 1888, that the Hungarian State takes upon itself the execution of these works, exercising the right of levying customs temporarily, such right being conferred upon it by the LVII. Art. of the Berlin treaty of 1878, and the VI. Art of the London treaty executed the 13th March, 1871. The law states, that the Minister of Public Works has to execute the above-mentioned works on the basis of the projects presented to the Legislature, and undertakes to make such dispositions as may be necessary in the interest of the successful execution of the works, and for their conservation and administration. The cost of these works—which are to be finished at the latest at the end of 1895—was fixed, with the proportions to be paid during progress, at nine million florins. By the Law Bill the Minister of Public Works was further entitled to fix, in conjunction with the Minister of Finance, the time and the way of levying the customs which Hungary will have the right to charge in virtue of the LVII. Art. of the Berlin Treaty on the trade ships for covering the expenses of the works. Finally, the law states that after the execution of the works an exact account is to be rendered to fix the cost of execution. The fixed amount, its annual interests and percentage of amortisation, the costs of administration and maintenance of the works, and the revenue resulting from the levied taxes, shall be the object of a special account.

The XII. Law of 1889 also provided that the costs of the works should be covered by the advances from the money stocks at disposition in the State treasury. The sum of 500,000 florins, required to begin the works, to procure the tools and machinery, to organise the direction of works, having been put to the disposal of the Minister of Public Works, all preparations and dispositions were made to begin these great works, which works had suffered so many long delays.

The largest part of the regulation works extending in the territory of Servia, it was the first thing to arrange between the two Governments for the free and uninterrupted movement for men and materials. As soon as this was done, the Minister of Commerce organised a technical bureau for surveying and controlling the execution of the works. This bureau had its seat in Orsova, and was constituted in the following manner:—Chief of the bureau, Ernest Wallandt, ministerial councillor; assistant, Alois Hoszpotzky, chief engineer; members: Ernest Jzsaky, ministeral engineer; Eugène Gruber, and George Kherndl, royal engineers. Later the minister delegated Francis Herbert captain of engineers.

The so organised technical bureau had at first to elaborate the particular plans, and to study the hydrographical condition of the section which was to be regulated. In the same time the minister made dispositions as to the modus and means to be employed in the most difficult part of the work, viz., the blasting of the rock under the water in the open river. He proposed to give a prize for explosive material to blow up the rocks under the water, and for the best systems with which the removal of the rocks under the water could be executed with success. The offers presented were put before a special commission, which examined the explosives and made several experiments on the spot. Moreover, the minister sent Mr. Béla Gonda—technical councillor and reporter of the Iron Gate business in the ministry—and Mr. Alois Hoszpotzky—chief engineer and assistant of the said technical bureau—to Bingerloch in order to study the works of blasting which were in execution. The result of this journey was a particular report, which contributed much to fix the practical execution of the works in question.

After a careful study of the nature of the works and modes of execution, the minister was convinced that it would be the best to execute this heavy work by contract. On the 5th December, 1889, he opened a public competition, and the advertisement in question was published which had regard to these works, without precedent in Europe and of an international importance. This was published on the Continent and abroad, and the plans and stipulations were put at the disposition of foreign contractors through the embassies. The date was fitted at 31st March, 1890, so that the competitors had four months to study the plans and the local conditions.

During this time the technical bureau finished the new survey and the elaboration of the plans, which were to form a completing part of the contract.

Moreover a great and difficult task was to be solved before the beginning of the work; the technical bureau had to determine on the whole length of regulation, the fixed points, and marks of low water, which the engineer, Paul Vásárhelyi; the author of the first plans of regulations, has fixed. With the aid of these old and somewhat defective data the bureau had to indicate the height of the lowest water in 1834, and fix them definitely afterwards by levelling, which was to furnish the basis of the large works in question, and to serve in future the requirements of those who will need to study the hydrographical condition of this section, and also for those who would execute these new works. The technical bureau thus accomplished a work of lasting value, and caused it sending copies of the lithographed plans to be sent to several scientific institutions and authorities. In view of the special nature of the works and of their great difficulties, care had to be taken to arrange so that some works might be executed under State supervision, and such precautions taken as were deemed necessary to ensure the execution of the works, notwithstanding any possible eventualities.

On the 31st March, 1890, four contractors presented their tenders. Two of these tenders concerned only a part of the works, and the two others demanded exorbitant prices, so that their tenders could not be accepted; but after long negotiations, one of the syndicates offered to accomplish the proposed works for nine million florins. In consequence of this, on the 22nd May, 1890, the final contract was let with the syndicate composed of Julius Hajdu, Hungarian hydro-technical engineer; Hugo Luther, manufacturer at Braunschweig, and the Berlin Discount Society. With this contract these contractors obliged themselves to finish the whole work by the 31st December, 1895. It was stipulated that the syndicate should begin the works within two months. The contractors took charge of the works on the spot on the 16th and 17th June, and began the same on the 18th September, 1890. They took charge of the grounds which were necessary for the working yards and quarries; this was not without difficulty, because the largest part of them are situated on the Servian territory; then lodgings for the workmen, offices, workshops, storehouses, &c., were soon erected. They began also to equip and manage the quarries, ordered tugs and pontoons necessary to the works, boats for measuring and surveying the rocks below the water stipulated in the contract, further boring machines, derocheurs, used for the removal of the rocks, ships, dredges: in one word, all dispositions were made in order to begin the works and to finish them in a comparatively short time. The question of the navigability of the cataracts on the Danube formed the object of international negotiations, several States being directly concerned, and had a universal importance.

(*To be continued.*)

## THE GENERAL SKINNER.

We illustrate this week a mining steamer, the fourth of the kind built by Messrs. Cox and Co., of Falmouth, for H.M. War Department. The boat has a length of 86ft.; beam, 18ft.; depth, 9ft. 4in.; the bunker capacity is 15 tons. She carries of water ballast 5½ tons. Lifting appliances consist of a bow davit derrick and two mast derricks, worked by steam capstans and engines manufactured by the same firm. The twin screw main engines are compound, with cylinders 11in. and 22in. by 15in., having one condenser with 400 square feet of cooling surface, in the centre and supporting both sets of engines. There is a separate auxiliary pumping engine, with cylinders 5½in. and 11in. by 10½in. stroke; the air pump is 10in. diameter; the circulating pump is 7in. diameter. There are double-acting feed and bilge pumps 2½in. diameter each; all pumps are 10½in. stroke. The main pumping engines are fitted with Marshall's valve gear; the propellers are of gun-metal 5ft. 9in. diameter, 6ft. 6in. pitch, and a total area of 9·9 square feet; the boiler is horizontal, multitubular, 10ft. 1½in. diameter by 9ft. 0⅛in. long; working pressure, 100 lb.; indicated horse-power is 320; revolutions, 220. This vessel is used for laying and raising submarine mines for defensive purposes and blowing up wrecks.

The Polytechnic Optical Relics.—Last Monday night two of the six old lanterns of the late Royal Polytechnic Institution, and a considerable number of specimens of the old hand-painted slides, were exhibited in the hall of the Lantern Society by Mr. Hay Taylor, with Sir Slingsby Bethel, president, in the chair. There was an overflowing attendance, including Mr. W. R. Hill, one of the lantern-slide painters to the Polytechnic. Although some good projection lenses were available, Mr. Taylor preferred to use the earlier ones employed at the Polytechnic, consisting each of a pair of plano-convex lenses, with their curved surfaces towards each other, on the ground that they gave a softer picture, more pleasing to the eye than if the pictorial outlines were sharper. By way of a change, it was a treat to see once again upon the screen lantern pictures not of quaker-like garb, but glowing with all the beauty of colours artistically laid on. The general result tended to raise the question in the mind whether photographic slides need necessarily be divorced from good colouring, and from the ideal side of art. For instance, outline pictures might be drawn on paper on a large scale by good artists, these outlines then photographed on glass, and painted by skilled artists as distinguished from ordinary colourists. Another plan would be to print excessively thin photographic transparencies on glass, merely to serve as a guide to the painter, and to be practically almost lost to sight by reason of his overlaid work. Most of the rising generation have never seen phantasmagorian effects produced on translucent screens by lanterns running on rails, nor the optical effects which can be produced by six lanterns working at one time, and such providers of popular entertainments as the Crystal Palace Company, who like attractions which involve little or no expense after the first cost, might do well in these days of lantern projection to consider whether the glory of artistic painting cannot be restored by their aid in these times to optically projected pictures. Anything of this kind should be done well or not at all. Mr. Edmond Wilkee, who, as we mentioned last week, bought up a vast number of the Polytechnic slides, and lent some of them for last Monday's display, was unfortunately unable to be present himself last Monday through illness.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### LOCOMOTIVES AND TRAINS.

Sir,—In reply to the letter from Mr. Norman D. Macdonald in your issue for November 16th, I beg to say that I simply took what I believe is the usual practice, namely, 50 per cent. of the weight of engine and tender, and the whole weight of carriages, &c., as brake pressure. I did not know anything about the composition or distribution of brake pressure on the train in question, excepting what I gathered from Mr. F. Bowles' letter of the 19th ultimo, so I simply took the brake pressure on the above assumption, upon which I based my calculations. I thought a comparison would be of interest in showing the relative retardation when only 50 per cent. and the whole weight of the engine and tender was taken as brake pressure, in the latter case the train would be equally braked. I stated "fully," instead of "equally," in my previous letter of the 5th inst., but, as I shall endeavour to show later on, the latter term is the most suitable to apply.

Of course the maximum efficient brake pressure, that is to say, the maximum pressure which can be applied without skidding the wheels, and which, as previously shown by me, varies according to the speed of the train, does not bear a constant ratio to the weight on the wheels braked, thus it has been found that at a speed of 7½ miles per hour—or 11ft. per second—a pressure of 1·04 of the weight on the wheels braked would produce skidding, whereas at a speed of 60 miles per hour—or 88ft. per second—the pressure might rise to 3·47 of the weight on the wheels braked before skidding took place. Let ($\mu$) and ($\mu_1$) represent the coefficients of friction in the former and latter cases respectively, then

$$1\cdot04\ W\mu = 3\cdot47\ W\mu_1$$

$$\therefore \frac{\mu}{\mu_1} = \frac{3\cdot47}{1\cdot04} = 3\cdot33.$$

Now ($\mu$) has been found to be about 0·24, and

$$\therefore \mu_1 = \frac{0\cdot24}{3\cdot33} = 0\cdot072.$$

Assuming the average coefficient of friction as 0·15, and $y$ as the average proportion of weight on wheels braked which may be applied as brake pressure without skidding the wheels, then

$$0\cdot15\ y\ W = 1\cdot04 \times 0\cdot24\ W = 3\cdot47 \times 0\cdot07\ W$$

$$\therefore y = \frac{1\cdot04 \times 0\cdot24}{0\cdot15} = \frac{3\cdot47 \times 0\cdot07}{0\cdot15} = 1\cdot6.$$

In taking the three cases proposed by Mr. Macdonald, I will assume that the weight on the wheels braked of the engines and tenders is 80 per cent. of the whole weight of these, as suggested by him.

We have therefore

(1) Engines and tenders. Pullman. Carriages.

$$\begin{aligned}\text{Brake pressure} &= 1\cdot6\,(0\cdot8 \times 162 + 25 + \tfrac{2}{3}\,169)\ \text{tons.}\\ &= 1\cdot6\,(129\cdot6 + 25 + 112\cdot66)\ \text{tons.}\\ &= 1\cdot6 \times 267\cdot26 = 427\cdot616\ \text{tons.}\end{aligned}$$

But $\frac{427\cdot616}{356} \,.\, 100 = 120\cdot1$ per cent.

and $x = 120\cdot1 \times 0\cdot15 = 18$ per cent.

$$\therefore 18 = 3\cdot34\,\frac{(60)^2}{d}$$

whence

$$d = \frac{3\cdot34 \times 3600}{18} = 668\text{ft., or } 222\tfrac{2}{3} \text{ yards.}$$

(2) Engines and tenders. Pullman. Carriages.

$$\begin{aligned}\text{Brake pressure} &= 1\cdot6\,(0\cdot8 \times 162 + 25 + 169)\ \text{tons.}\\ &= 1\cdot6\,(129\cdot6 + 194)\ \text{tons}\\ &= 1\cdot6 \times 323\cdot6 = 517\cdot76\ \text{tons.}\end{aligned}$$

But $\frac{517\cdot76}{356} \,.\, 100 = 145\cdot43$ per cent.,

and $x = 145\cdot43 \times 0\cdot15 = 21\cdot81$ per cent.

$$\therefore 21\cdot81 = 3\cdot34\,\frac{(60)^2}{d},$$

whence

$$d = \frac{3\cdot34 \times 3600}{21\cdot81} = 551\cdot3\text{ft., or, say, } 552\text{ft.} = 184 \text{ yards}$$

(3) Tot. w'ht of train.

$$\begin{aligned}\text{Brake pressure} &= (1\cdot6 \times 356)\ \text{tons}\\ &= 569\cdot6\ \text{tons,}\end{aligned}$$

But $\frac{569\cdot6}{356} \,.\, 100 = 160$ per cent.,

and $x = 160 \times 0\cdot15 = 24$ per cent.

$$\therefore 24 = 3\cdot34\,\frac{(60)^2}{d},$$

whence

$$d = \frac{3\cdot34 \times 3600}{24} = 500\text{ft., or } 166\tfrac{2}{3} \text{ yards.}$$

This gives a saving in stopping distance of (668 − 552) = 116ft. in the (2) over the (1) case, and (668 − 500) = 168ft. in the (3) over the (1) case, or (552 − 500) = 52ft. in the (3) over the (2) case. The (3) case appears to agree very well with the results of an experiment recorded in a paper read by Captain Douglas Galton, before the Institution of Mechanical Engineers in 1879; the quickest stop which had then been made was in the case of an experimental van, fitted with the Westinghouse automatic brake, which was slipped from a train travelling at a speed of sixty miles per hour, and stopped in a distance of 167 yards. We have in this case

$$x = 3\cdot34\,\frac{(60)^2}{167 \times 3} = \frac{4008}{167} = 24 \text{ per cent. as the average retardation.}$$

The above figures are based on the assumption that the average coefficient of friction is 0·15, and that the frictional resistance, or retardation, is a constant quantity, and also that the brake force, or pressure, is acting at its maximum efficiency. It is quite possible for all the wheels of a train to be braked, including those of the engine and tender, and yet if the brake pressure is not applied at its maximum efficiency, the retardation may be less than if only a proportion of the wheels are braked, but at a maximum efficient pressure corresponding to the speed of the train, as before explained.

Now the weight on the wheels braked may be 80 per cent., or thereabouts, of the whole weight of engines and tenders, but the applied pressure would according to the general practice stated by me, be about 50 per cent. of the total weight, or 62½ per cent. of the weight on the wheels braked; whereas, in the case of carriages, the brake pressure would be equal to the weight on the wheels braked, assuming the pressure to be equally distributed on all the wheels, or if only four out of six wheels are braked—or 66⅔ per cent. of the whole weight—then the brake pressure would be one and a-half times the weight on the wheels braked; the engine being braked less to give a certain amount of drag on the train, as previously shown.

There is one point I should like to call attention to, viz., the sudden increase of friction between the wheels and rails—when the former are skidded—at the moment of just coming to rest. In this case the coefficient of friction is about 0·24, whereas at a speed of 10ft. per second it is only 0·088, at 20ft. per second 0·072, and so on, decreasing as the speed increases. It is no doubt due to this fact that the sudden jerk or jar is sometimes experienced when a train is stopped; the general rule with drivers is to release the brake pressure just before coming to rest, and then, if necessary, to finally apply it by means of the hand-brake to prevent the train rolling away, such as would occur on an incline.

With regard to the American practice of braking all the wheels, even of the bogies of engines, as stated by Mr. Macdonald, and their non-experience of jar on the application of the brake, I would suggest that it is quite possible, even under such circumstances, to so distribute the brake pressure—by means of the brake cylinders and brake gear—that less pressure in proportion to the weight on the wheels braked should be applied to the engines and tenders as compared with that applied to the cars, &c., so that the necessary drag of the engine and tender on the following coaches is obtained. I do not know for certain if this is the case, but it may be possible that it is so. Perhaps Mr. Macdonald, or some of your correspondents, can enlighten us on this point.

24, Harrington-square, **EDWARD J. M. DAVIES.**
London, N.W., November 19th.

SIR,—Mr. Macdonald appears to overlook the fact that old North-Eastern types of engines are very frequently used as substitutes—in fact, there seems to be a greater number of the Tennant's working the main line trains than all the other types together—for the compound and 1622 classes. If Mr. Macdonald will make a few inquiries he will learn that one at least of the Tennant's has for a considerable time run in the regular No. 1 or North link, and manages, generally speaking, to keep time, whatever the train may be to which it is attached. If a comparative statement could be obtained, showing (1) the number of turns missed by the different types (2) their average consumption (3) time lost on journey and weight of train, it would be very instructive, I have no doubt; it would give a very good index to the increased cost of working. I think it would not show that any great improvement had been made in the North-Eastern locomotives.

Will Mr. Macdonald kindly say where and upon which train the booked time has been reduced? I am afraid that he will find "the reduction" is more fancied than real. I think the weight or number of the carriages has not increased in the same ratio as the engines. My experience is, that whilst the weight of the train has remained almost stationary, the engines have increased at least 10 per cent. If this deduction is correct, there must be an increase in the wear and tear of the permanent way, beside the first cost of the engine. I hope Mr. Bowles may be persuaded to divulge the whereabouts of the mysterious "McDonnell." **H. FRANK.**

Gateshead, November 22nd.

SIR,—I have read your correspondence on the above subject with much interest, and with your permission I should like to say a few words about the matter. The use of pilot engines has now become so frequent that the comparison in weight between our trains and those of other countries is hardly fair, despite the general greater speed of the former. I cordially agree with "E. B. D." that were it customary to take pilots on the Great Northern, many of the trains that are taken with ease by one engine would be assisted, were they to be had for the asking. I believe I am right in saying that the Great Northern is the only line on which this rule holds good. Even the South-Western, with their coupled leviathans, find it necessary to pilot their heaviest trains, and in the summer train after train may be seen leaving St. Pancras terminus with two engines. During the holiday season 11.25 a.m. ex Paddington generally consists of ten eight-wheelers and two engines, the 3 p.m. nearly always two for about the same load. That the engines can take the load without a pilot there is little doubt, because I have seen an ordinary 7ft. single take weights considerably in excess of this with trains nearly as fast. A short time ago, the up South Wales corridor, due at 2.35 p.m., arrived with eleven eight-wheelers, among them five heavy corridor coaches, two six-wheelers, and one four-wheeler, or at least 240 tons, with one engine. Again, 5.45 p.m. into Paddington sometimes consists of eleven eight-wheelers and one six-wheeler, with only one engine. Now, if engines of old design can take the heavy trains mentioned above—and they are not the only instances by any means—unassisted, it is surely rather a hopeless confession of failure to say Mr. Dean's new singles are unable to take lighter trains at a slightly higher rate of speed without a pilot. Perhaps his latest productions, the Armstrong class, may distinguish themselves in weight pulling. They seem to be doing but little at present. **A. HOCKLEY.**

5, Westcombe Park-road, Blackheath, November 26th.

SIR,—Your correspondent, Mr. Archibald P. Head, is right in his conclusion that the best regular express service in the United States is at least as fast as that of our own country, but the trains he has chosen as representative examples do not do full justice to either side. The down Empire State Express runs from New York to Buffalo in thirty-five minutes less time than the corresponding up train by which Mr. Head travelled.

Mr. Head is also certainly wrong in choosing the East Coast down Scotch express to represent this country. The West Coast up Scotch express is distinctly faster, and most people will probably agree that it is the best long distance train which we possess. I append a tabular statement, which your readers may compare with Mr. Head's figures:—

*Empire State Express.*

* Including one short stop.

November 26th. **NORTH WESTERN.**

SIR,—Your correspondent "Permanent Way," gives this week "an answer to those people who denounce the ponderous locomotives of the day as incapable of giving any better results than their predecessors." I am not aware that anyone has maintained anything so fatuous as this general proposition. It has been said that *certain* recently built locomotives of great weight and high cost seem unable to do their work any better than, or even as well, as the cheaper and lighter engines they were intended to replace. This is a very different matter.

In connection with the brilliant running on the Caledonian railway, "Permanent Way" seems unaware that, though the actual engine may have been new, the *design* is as nearly as possible that of the North British "Waverley" class, which has been at work for eighteen years, so that, in this particular case the argument in favour of the modern engine completely falls to the ground. In this list of heavy British rolling stock, your correspondent leaves out the Great Northern dining cars, after which it is scarcely surprising to find that in speaking of engines with 19in. cylinders, he omits all mention of the company which in this respect has had more experience than any other in the kingdom. **W. B. THOMPSON.**

London, November 28th.

SIR,—The letter by "Permanent Way" in your last issue, was most interesting, especially the account of the run from Symington to Carlisle at a mean speed of 60·7 miles an hour, by a four-coupled Caledonian engine with 6ft. 6in. wheels and 19in. by 26in. cylinders. "Permanent Way" says, "the most extraordinary feature in the run is the fact that the maximum speed only reached 72 miles per hour." Here I cannot agree with him, however. I consider that 72 miles an hour is a remarkable performance for a locomotive with only 6ft. 6in. wheels. The piston speed of the engine at this velocity must have been 1343ft. per minute. At such a speed as this it seems probable that the internal resistance of the engine due to friction, back-pressure, &c., must have become so great as to counterbalance the propelling forces due to the engine and gravity. Were a similar engine with 7ft. wheels used, the piston speed at 72 miles an hour would be reduced to 1248ft. per minute, with 7ft. 6in. wheels to 1165ft., and with 8ft. wheels to 1092ft. per minute. Or suppose we consider 1343ft. per minute as the maximum piston speed, then the 7ft. engine would run at 77, the 7ft. 6in. at 82, and the 8ft. engine at 88 miles an hour. On the other hand, the tractive power per pound of mean effective pressure would be as follows:—6ft. 6in., 120 lb.; 7ft., 112 lb.; 7ft. 6in., 104 lb.; 8ft., 96 lb. This would mean a loss of time up the banks for the larger wheeled engines, but on the run in question, where 38¾ miles are downhill, and the worst bit of uphill is a short piece of 1 in 100, a 7ft. coupled engine would probably have made better time.

London, November 27th. **U.**

SIR,—I am sorry to see Mr. Bowles's statement that he has written for the last time, as we have not yet had an answer to my question, "On what railway the locomotives with pick-up he mentioned were to be found?" **SCRUTATOR.**

London, November 23rd.

### GOVERNING ELECTRIC LIGHT ENGINES.

SIR,—I am sorry your correspondent, Mr. Kuhne, finds my letter so trying to his temper, but he appears to have been in such an unusual hurry to lose it when he read my first letter that he has quite overlooked the statement—"If the range of cut-off were limited to 55 per cent. and with the allowance of 6 per cent. for condition of edges, &c., the negative advance angle for this range would be such that there would be no break in the control throughout"—and might have spared himself the mortification of being a "little too previous," as the negative advance angle for 55 per cent. range—with the above allowance—is just 12 deg., and he states in his last that the apparatus under discussion is, at all times, limited to 10 deg. negative advance angle, so that actually he had nothing to lose his temper over. Of course he does not distinctly state that the negative advance angle is 10 deg., but allowing for his error of statement that is what his positive angle of 80 deg. really means. I notice, however, from the diagram he sends that the latest trip is arranged to occur about 20 deg. before the extreme position of the apparatus excentric, and as 10 deg. negative advance angle gives a theoretic range of 58 per cent., this allowance of 20 deg. reduces the range to 41 per cent.—that is, to position I of the diagram—a magnificent result truly for an independent excentric gear.

I do not think anyone who at all understands these gears will expect to find X of Fig. 3 as an important function of my diagram, and I might mention that the figure in question accompanied what I take it was an inspired article on the Marshall construction in the *Practical Engineer*. I am obliged by his spreading the knowledge of my diagram amongst the engineers he mentions, and am sorry for the result, but as he is no doubt aware there are engineers and engineers, and I am not greatly surprised to find him pointing out the misprint of O E for O F, although the sequence of the positions noted might have set him right, even when the diagram did happen to be a quarter turn out of phase and $R_2$ misprinted for $K_2$. Little matters trouble great minds.

I will not doubt his sincerity when he says he does not understand my diagram, but it appears strange when he says he understands Dr. Proell's diagram—Professor Sweet's in America—for in the same way that Dr. Proell's diagram is a modification of Reuleaux's diagram, so is my diagram a modification of Professor Zeuner's diagram, and in intelligent hands both may be made to show the same results, but as in the originals, with much less trouble in the case of my diagram. The outer circle of the Proell diagram is quite superfluous, except it be used to indicate leverages, the whole action being obtained from the inner circle, &c. If Mr. Kuhne will describe on M O of Dr. Proell's diagram a circle, and through the point where the lead angle cuts this circle describes a circle with O as centre, then he has my diagram, and very little reflection will show that all openings or distances moved may be measured direct on the lines indicating the various crank positions, a result not obtained previously except by a separate geometrical construction for each different position. Coming to your other correspondent, Mr. Cameron, if one judges by the statements in his last letter, his is a most remarkable apparatus. In the *Mechanical World* of 10th August last his apparatus was stated to give a range of three-quarters of the stroke when driven by an independent excentric.

This my diagram showed to be impossible when the valve lifters were closely bridled to the valve spindle. Now he states that the range is from zero to five-eighths of the stroke, with a negative advance angle of 80 degrees. As in Mr. Kuhne's case, this last is an error of statement, and really means a negative advance angle of 10 degrees, but the remarkable part is that this angle is expected to give the range of five-eighths, when, as shown in the case of the Proell apparatus, the range is only 41 per cent. No doubt Mr. Cameron will explain this to his own satisfaction, but nothing but sheer perversity will account for his statement, as also that of Mr. Kuhne, that entirely different considerations to that of lapse in the control prompts the use of an open bridle on the valve lifters. At any rate, I shall be much surprised to hear of either of them having the hardihood to offer to anyone an apparatus with a close bridle, and of which the certainty of action depends on some uncertain time interval that alters with the governor height, for although the statement I have quoted from my first letter at the commencement of this says, that with an allowance of 6 per cent. of the stroke there would be no break in the control, it was more with the object of directing attention to the necessity of such uncertain allowances that the statement was made at all, for I have watched a Proell apparatus, which I presume was erected according to proper instructions, and in it the action I mention actually takes place, the owner being much surprised when I pointed it out to him. **JAS. DUNLOP.**

November 26th.

### MINE EXPLOSION RELIEF FUNDS.

SIR,—In your very interesting and instructive leading article in your last week's issue, upon "Mine Explosion Relief Funds," you state that the dispute over the Albion funds has been settled by a compromise which gives the widows an additional 2s. per week to the 5s. they get from the South Wales and Monmouthshire Permanent Relief Society, making it up to a total of 7s. per week, and also an increased grant to the children. I am sorry to say that this statement is not correct, for there has been no compromise; although the Permanent Society have secured from £25,000 to £30,000 of the money that has been contributed by the public for the relief of the Albion widows and children; and, according to the statement made by the Permanent Society's solicitor—at the Pontypridd meeting—the fund would give no additional payment to the 5s. for the widows and the 2s. 6d. for the children, no matter how much of the public money they may get. Since then, owing to the great indignation shown by the public, the Permanent officials have offered—unofficially—to adopt the Llanerch Colliery scheme if all the money collected is given to them to distribute. The widows, workmen, and their leaders refuse to accept this offer, as they contend it would not be doing justice, because the Llanerch widows if they have six children only get 6d. per week in addition to what they are legally entitled to from the Permanent fund; if they had four children they would get 1s., if no children at all they would get 2s., which would make their weekly payment up to 7s. per week. To my mind the Llanerch scheme is a most unfair one, and is not one that I could recommend the widows to accept; for although the fact of the widow having six children would reduce her increased grant from 2s. to 6d., still she would not get a farthing extra for either of the children in addition to the 2s. 6d. she would be entitled to. Whether the deputation of miners' leaders selected to meet the board of management of the Permanent Society will be able to agree upon a fair compromise, I am not at present in a position to say; but it is sincerely hoped that all controversy will be put an end to by adopting some scheme with a central trust, which would act as receiver and guardian of all money that would be subscribed by a generous public out of fulness of heart for the relief of those widows and orphans who lose their bread-winners by colliery explosion; and unless some such scheme is devised, which would put mine explosion relief funds upon a satisfactory basis, the result will be, I am afraid—if this squabbling between interested parties is continued—that, no matter how great the distress or serious the disaster, the public will be so disgusted as to close their pockets against all appeals for relief that may be made in the future. **WILLIAM BRACE,**
Newport, Mon., November 22nd. Miners' Agent.

### EXPLOSIVES FOR MINING PURPOSES.

SIR,—I have read a letter from the Secretary of the Roburite Explosives Company, Mr. Krohn, which appeared in your paper of November 16th. It is absurd to suggest a doubt of the report signed by Messrs. Matthews, H.M. Inspector of Mines, R. Isherwood, J.P., miners' agent, and J. Burrows, of Messrs. Fletcher, Burrows, and Co., who in the public interest superintended the experiments at these collieries on October 24th, when Westphalite undoubtedly proved to be the safest for use in coal blasting, carbonite and Ardeer powder being out of the running on account of their much inferior power.

From the results of experiments which I have since conducted in the presence of other managers connected with collieries, I am perfectly satisfied that either a No. 6, 7, 8, 9, or 10 detonator will completely detonate and explode Westphalite, and without igniting a highly inflammable mixture of coal dust and fire-damp when fired under the severe conditions of an untamped shot. The Westphalite I have experimented with has been in our magazine about two months, and it is in excellent condition and perfectly dry, the experiments we made underground being very satisfactory.

From a pamphlet of the Federated Institution of Mining Engineers, being a reprint of the report of the French Commission on the use of explosives in the presence of firedamp in mines, page 143, Roburite has been proved to produce flame with tamping, particulars of which are as follows:—"Experiments at Anzin on the flame produced by explosives: Roburite, 3247 grains—under 21 oz.; length of stemming, 7·87; result, flame."

I am not interested in any explosives company, but as manager of extensive collieries it is my duty to use that explosive which offers the greatest safety combined with efficiency. I have had the advantages of the most perfect experimental station for testing explosives hitherto erected in this country, and, having due regard to weights and quantities as they are used in the pit, I am compelled to admit that Westphalite has never failed under the most stringent conditions, when fired by any of the detonators previously mentioned; whilst Roburite, under similar and more favourable conditions, has invariably ignited and exploded coal dust and mixtures of coal dust and gas, producing flame from 30ft. to 50ft. long. **JOHN KNOWLES,**
The Pearson and Knowles Coal and Iron Company,
November 24th. Ince, Wigan.

### LABOUR AND LUXURIES.

SIR,—The main contention of "Y. X.," that gold is a benefit to society, if spent no matter how, is so clearly stated, and yet so clearly wrong, that I am surprised this Goliath has not been slain by your able correspondents. With your leave, Sir, I would remind them that "Y. X." in, I think, his second letter, says you cannot refute him without introducing "a time limit." I take it the following is a fair illustration of the point. A man buys a £1 air-gun, and slily breaks the windows of a number of rooms occupied by poor tenants, who paper them up. The man gets into gaol for a fortnight; his arrest, trial, and nearly all his keep is dead loss to the ratepayers; he only returns them the oakum picked. The £1 for the gun does good at the start, and a fortnight after the landlord puts the glass in; the money for the glass does good, but the landlord has a corresponding loss.

Will "Y. X." contend that the £1 could not have been spent without the loss as a necessary result? And if so, what of his contention? Allow me, in conclusion, to point out that THE ENGINEER usually deals with problems involving the use of time, weight, and distance, and I do not think an argument on this subject sound which calls for the surrender of a time element. **J. C. S.**

Dudley, November 26th.

### AN ANCIENT FORGING.

SIR,—In the forecourt of the Royal United Service Institution, Whitehall-yard, among the few relics that are too big to be stored inside, there is to be seen in the place where it has lain for many years an anchor which—as the tablet upon it tells—formed part of the equipment of one of the Spanish Armada ships, sunk to the bottom of the sea in 1588. The anchor was dredged up more than a hundred years later, covered inches thick with a conglomerate of shells and pebbles. The anchor is about 10ft. long and 5ft. across the flukes, and as far as one can guess the dimensions of the iron, it must weigh fully 10 cwt. The anchor was no doubt forged in the Navy yard at Cadiz; it is extremely interesting as a specimen of the blacksmith's art of three hundred years ago. One is curious to know what kind of tools were then available. The immediate object of this letter is to save this relic from destruction. The present house of the institution is shortly to be pulled down, and at the handsome new building now nearly completed in Whitehall, next door to the Chapel Royal, there is no forecourt in which to exhibit the anchor to the passer by. Even if the anchor be moved to some safe place it will have to be handled tenderly, or the coating of barnacles will be injured. Let us hope that it will be reverently treated by its present guardians, that it be neither lost nor thrown aside; and if a place be wanted for it there are doubtless many engineers or ironworkers who would gladly possess it. As the emblem of the Royal Navy, could not this anchor with its tablet be placed in the centre of the forecourt of the Admiralty close by? **EWING MATHESON.**

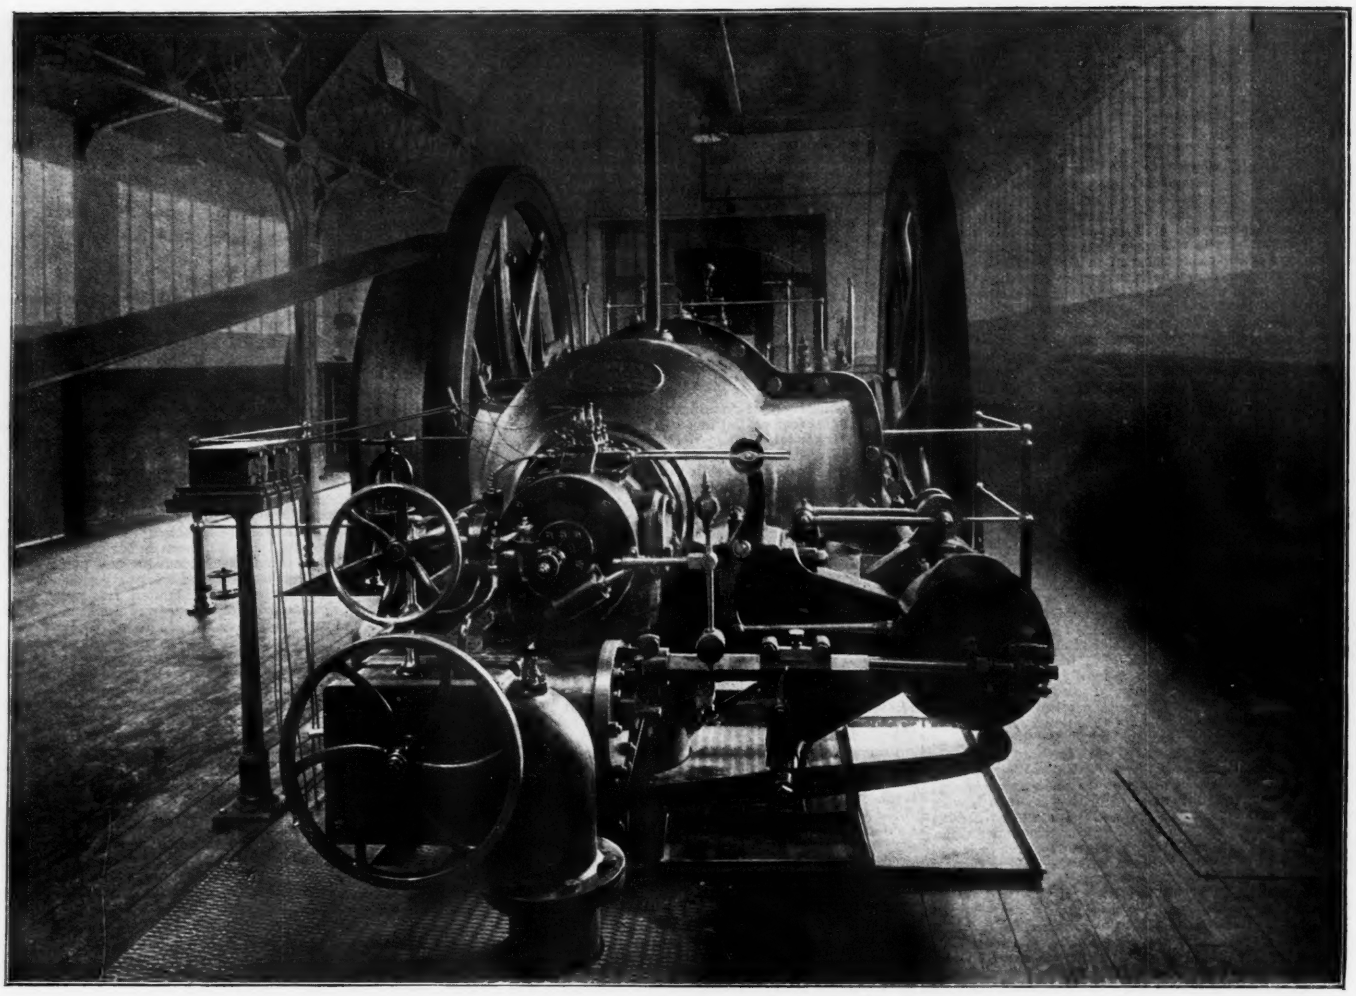
November 26th.

(*For continuation of Letters see page* 467)

RAILWAY ECONOMIES AND DIVIDENDS.—A certain large railroad has saved during the past year enough to pay a small dividend, by economising in what are usually called small details. This statement, the *Railroad Gazette* says, was recently made on good authority, and "we asked an officer of the road to tell us what these details were; concrete facts make mighty interesting reading in such a case. He will not do this, but his answer is worth reading, nevertheless, and we print it in this issue, headed: "The Day of Small things." While the article consists mostly of generalities it must be remembered that it is from a man who has applied these to particulars and found that the process paid. It sometimes seems as though the railroad era in this country might be divided into two periods; the first when the roads were small and could manage details economically, but did not need to, because they were rich; the second when they are in pressing need of every cent that can be saved, but are so big that it is impossible to watch the leaks. The success of our correspondent may be said to be due to the adaptation to a large institution of methods which are well known and familiar in smaller ones."

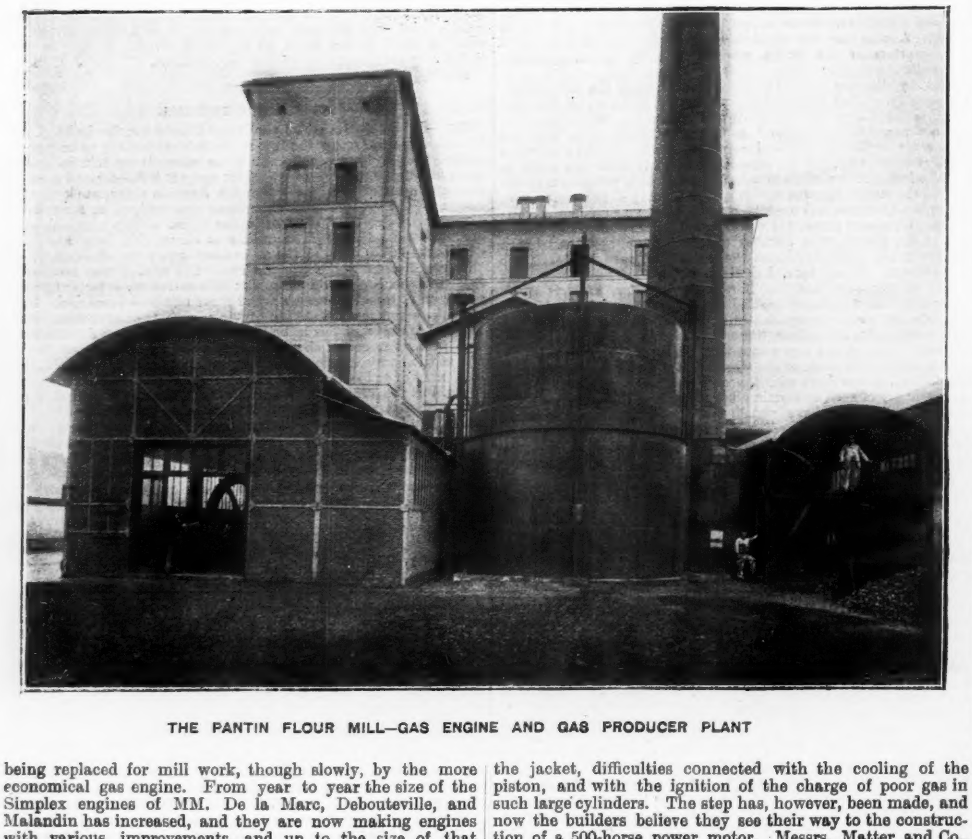
# THE SIMPLEX GAS ENGINE—PANTIN FLOUR MILLS, FRANCE

DELAMARE DEBOUTEVILLE AND MALANDIN SYSTEM—M. MATTER ET CIE., ROUEN, CONSTRUCTORS



## 320-HORSE POWER SIMPLEX GAS ENGINE AND THE PANTIN FLOUR MILL.

One of the largest, if not the largest, gas engines yet in actual regular work is the Simplex engine, now and for some time driving the large flour mills of M. Le Blanc, at Pantin. It is worked by producer gas, and affords another illustration of the certainty with which the steam engine is being replaced for mill work, though slowly, by the more economical gas engine. From year to year the size of the Simplex engines of MM. De la Marc, Debouteville, and Malandin has increased, and they are now making engines with various improvements, and up to the size of that we now illustrate. They made a great advance when they constructed and successfully worked the 100-horse power engine which we illustrated two years ago, but the jump to 250-horse power still in a single-cylinder was an even greater stride, and now they have made the further advance to 320-horse power. The difficulties are not in the construction of an engine which will withstand the heavy pressures, but which will withstand these when aggravated by the differential stresses which result from the high temperature of combustion, and the unequal effect of the cooling water in the jacket, difficulties connected with the cooling of the piston, and with the ignition of the charge of poor gas in such large cylinders. The step has, however, been made, and now the builders believe they see their way to the construction of a 500-horse power motor. Messrs. Matter and Co., of Rouen, the licencees under the Simplex patents, are quite satisfied on this point, and are to be congratulated upon their successful introduction of the gas engine and gas producer in the fine new mill we illustrate, which is fitted up with most of the new kinds of milling machinery.



THE PANTIN FLOUR MILL—GAS ENGINE AND GAS PRODUCER PLANT

*Production of the gas.*—The gas producers of the Buire-Lencanchez system, constructed by Messrs. Matter and Co., are in two parts, coupled in such a manner that they can be worked together, or independently when it is necessary to clean them or their fires.

The engine runs day and night without stop, because the mill cannot be stopped except for accident or reasons beyond control, and hence the double arrangement of producer is essential.

Each gas producer is supplied with the necessary quantity of air for gas production by a fan according to the demand.

From the gas producers, the gas passes through a series of cooling pipes to a washer, consisting simply of a column of coke through which water trickles, gas being thus filtered, cooled, and robbed of much of its tar. From this it passes away to a purifier, filled with dry coke, and thence to the gas holder.

By means of the arrangements adopted the employment of gas regulator bags of india-rubber is no longer necessary.

*The gas engine, construction.*—The engine is of the Simplex type, but it has been re-designed by the inventors with respect to the sections and the arrangement of the valve gear, &c.

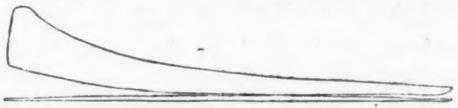


DIAGRAM FROM SIMPLEX GAS ENGINE

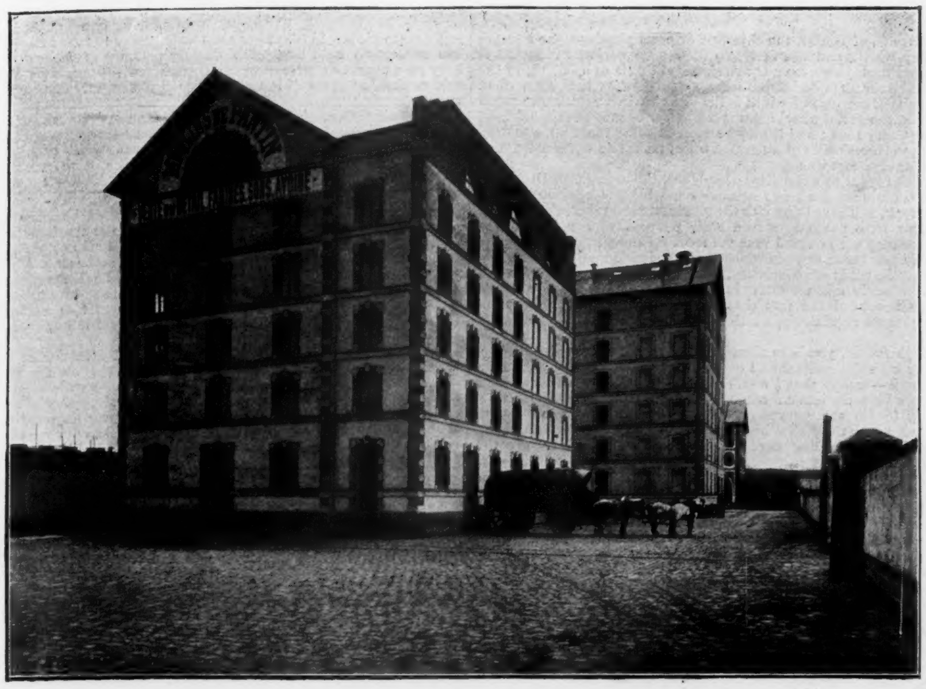
The diameter of the cylinder is 0·87 m. or 34·5in., and 1 m. stroke, or 39·37in. With the poor or producer gas it gives 320 indicated horse-power, or 250 brake horse-power.

With such large dimensions and large forces, the questions concerning the temperature of the cylinder, the thickness of the metal, that of the jacket, the exhaust valves, and of the piston become difficult, and great care has to be taken to prevent over-heating, and to secure as near as possible a regular mean temperature of cylinder walls. The running day and night adds to these difficulties.

*Consumption of fuel.*—The fuel employed is the dry coal of the Anjou mines. As a brake trial of so large an engine, and in the place where it is fixed was almost impossible, and also because the stopping of the mill for the purpose would be necessary for some hours, the makers had to be content to make a trial with the engine doing its ordinary work, but as this trial was carried on for a long time, it is deemed to be of equal practical value. The figures obtained relate to complete day and night runs, no stops having to be allowed for, and variations of load from one instant to another neutralise each other. A first trial was made in the month of February in the following manner.

Two wagons of 10,000 kilos. each, were set apart for the trials, and the gas producers having been filled up to the top with other coal, the hour of starting was taken. The mill being worked according to a determined invariable load, there

# THE PANTIN FLOUR MILL, FRANCE



was no necessity for constant observations of brake load or to take frequent indicator diagrams. When the two wagons had been emptied of their contents, the gas producers being filled up to the top with the last coal, the time was noted, and it was found that the run had lasted 194 hours.

The diagrams taken from time to time gave a maximum of 280-horse power, corresponding, it is stated, by reference to other experience, to 220 brake horse-power. The gross consumption of coal, no deduction being made for cinders or ash, was thus:— $\frac{20,000}{194 \times 280}$ = Ok. 368 grammes per indicated horse-power, or 0·788 lb. per Fr. horse-power and 0 803 per British horse-power; $\frac{20,000}{194 \times 220}$ = Ok. 468 grammes per brake horse-power, or 1·028 lb. by Fr. brake horse-power, or 1·043 lb. per British brake horse-power.

The consumption of jacket cooling water during this trial was 6100 litres per hour and less than 3000 litres for the washer and the two gas producers combined. This is a consumption total of 41·3 litres, or 58·3 lb. of water per brake horse-power hour, or very much less than the best condensing steam engines would use, but more than double the water that would be required for the best non-condensing engines. In most cases the water costs little or nothing, and the results as to coal consumption need no comment. Even if a different relation is assumed between the indicated and brake horse-power the cost of the horse-power hour from a gas engine and gas producer is, as has been shown in this country, so much less than by the steam engine that it is remarkable that the cheap gas system has not made more rapid progress, or that the designers of gas producers have not succeeded in making an apparatus which will comply with the requirements as to uniformity of quality of product, and at the same time either uniformity of quantity or conformity of quantity with variable requirements.

Three months after the above-mentioned trials, others were made which confirmed the results previously ascertained.

*The mill.*—The Patin mills were completely reconstructed in 1890. They are exceptionally well placed, the grain and the products being easily taken from or to Paris; they are on the Canal de l'Ourcq and on the Chemin de Fer de l'Est. On arrival by either road, rail, or water the wheat is received into a large building of silos, where the wheat is cleaned, graded, seasoned, and mixed by the necessary machinery and conveyors. From this building the grain is carried by a belt conveyor, where, after passing through a further cleaning in a cleaner and brusher, it passes to the first and following roller mills arranged in two long series, all connected to the scalpers, sifters, purifiers, and germ separators, which form the complete and regular automatic series of a modern flour mill.

From this building the products finally emerge into a third, where the sacking and despatch is carried on chiefly to Paris, and the hand labour is reduced to a very few beyond those required for the last-mentioned work. The lighting of the mill is by 300 incandescent lamps and dynamos driven by the gas engine, which also drives the pumps necessary to provide water for its own use and for grain cleaning. The mill, we are informed, is one which does great credit to those who own it, and those who have built, arranged, and equipped it.

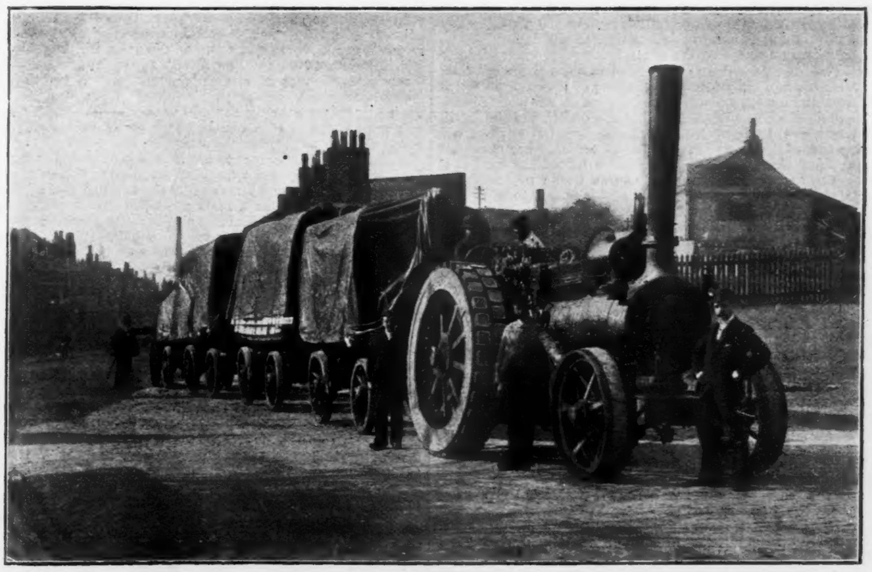
Particular attention is drawn by M. Delamare Debouteville to the gas producers of MM. Buire and Lencauchez as having removed the difficulty which has hitherto stood in the way of the cheap gas for this purpose, namely, the necessity for anthracite coal. They now use the coal of almost any district at about half the cost of anthracite in some places. The gas is, however, very poor, and the Simplex engines referred to have had to be proportioned and arranged with a view to this quality. The bituminous and even some semibituminous coals are not yet, however, considered to be within the province of practical use for this purpose, chiefly because of the difficulty with the tar and of tar extraction. It is considered necessary that efforts should be made to construct gas producers which will utilise not only the suitable coal, which is in lumps or pieces of various sizes, but the fine and powdery coal. This is looked upon as the thing to secure the final success of the gas engine as against any other motor. The use of these coals would no doubt contribute very much to this end, but with these, as with the anthracite, they must be carefully sorted or graded as to sizes of pieces or grains, just as the anthracite coal proprietors and users in the United States have found it necessary to sort anthracite into different sizes for different purposes, and to sell or attempt to use none which is not of grains or pieces of nearly uniform sizes.

## LETTERS TO THE EDITOR.

(*Continued from page* 465)

### TRACTION ENGINES.

SIR,—I have carefully read your remarks about wheels. Their construction is of the utmost importance. It is forty-six years since I first ran by steam on common roads. I have run 100 miles per day by steam on common roads, some of which I believe you have records of in your paper nearly thirty years ago. Nearly the whole of the London Traction Engine Company's engines came into my hands when they gave up thirty years ago, so I can speak with some confidence.



TRACTION ENGINE WITH BOULTON WHEELS

The enclosed photograph may interest your readers. It shows wagons being hauled by an engine with my spring wheels. There are about twenty pairs of my wheels at work daily. Many of them have been at work more than six years every day, and are working to-day. The first pair I made were for Messrs. J. H. Gartside and Co., Wellington Mills, Ashton-under-Lyne, and they were so well pleased that they have had three other pairs for other three engines.

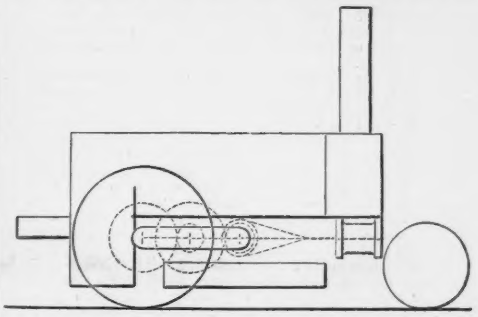
ISAAC WATT BOULTON, Ashton-under-Lyne.

SIR,—I quite agree with you that one "important question is the construction of the wheels." It is well known that the "Highways and Locomotive—Amendment—Act, 1878," requires that the driving-wheels of a locomotive shall be cylindrical and smooth soled or shod with diagonal cross-bars of not less than 3in. in width nor more than ¾in. in thickness, extending the full breadth of the tire, and the space intervening between each such cross-bar shall not exceed 3in. In my opinion this law ought to be amended. If the wheels are smooth soled they slip; if they are shod with diagonal cross-bars they damage the roads. These two propositions require no proof beyond that of experience. You ask "How does wood answer?" I reply, very well indeed. During the past six or seven years it has been my duty to examine and note the difference between the wheels made according to law and Boulton's patent traction engine wheels. With respect to the latter, perhaps I may be allowed to say that the periphery of the wheel is divided into sixty-eight cells or compartments about 6½in. square and 9in. deep. In these cells or compartments hard wood blocks are loosely fitted so that they will move easily about, with the grain of the wood pointing outwards, each block being bound with an iron strap about ¾in. from the end. The blocks are bedded on an india-rubber or other pliable cushion, and are loosely attached to the wheel by bolts let some inches into the wood. The head of the bolt is covered by a wooden plug; the bolt passing through the cushion is secured on the wheel by a nut. As the wheel revolves the weight comes on to three, four, or five of these blocks, as the case may be, the cushion gives way, the bolts are pushed up, and the blocks adapt themselves to the surface of the road. I have watched these wheels at work on scores of occasions, and I have never been able to detect any damage that they have done. Moreover, there is scarcely any vibration. I am certain that they are an immense improvement on the old ones. I have not the slightest interest in the manufacture of these wheels, so I simply sign myself

EXPERTO CREDE.

November 26th.

SIR,—With reference to your remarks on design of traction engines, some fifteen years since I saw in the suburbs of Paris a traction engine which would meet all the objections to the present designs. I send a sketch from memory, which will explain its construction. The engine was on springs; the gearing was carried by two parallel beams attached at one end to the crank-shaft, the other to the axle. There were two cylinders, but no fly-wheel, or possibly a very small one. The tires were of hard wood, the grain



of the wood being set on end as in wood paving. The wheels were smaller both in diameter and face than is usual in English engines. It was evidently intended for road work only and not to travel on soft ground.

Perhaps some of your correspondents in France can give further particulars of what appeared to be a very useful engine.

Farnham, November 24th. JOHN HENRY KNIGHT.

SIR,—I am pleased to see that you are still continuing the discussion upon the traction engine question; but you complain that no practical suggestions have been offered for any alterations in the Highway Acts. In my opinion, one of the most pressing needs of traction engine owners is the prevention of the passing, by small local authorities, of arbitrary bye-laws directed solely against traction engine traffic. The Highway Amendment Act of 1878 partially effected this, but still allows too much latitude. The highway or street committees of county boroughs are small in numbers, and liable to be too much influenced by one or two prejudiced or narrow-minded members, who would, if possible, prevent all traction engines from passing through the borough limits.

Your article is valuable from many points of view. Regarding the improvement in external appearance of the traction engine, provided the motion, gearing, and fly-wheel are hidden, there is no difference whatever between the present type of traction and the road roller. It is a case of the survival of the fittest. The chief reason for the retention of the present form is its general adaptability for either locomotive or for stationary work, for any purpose to which an engine can be put. There would be serious mechanical objections to the adoption of your suggestion of placing the motion beneath the boiler. If I recollect rightly, an engine of this type was exhibited at the Royal Show some years since, with Whittingham's driving gear, but the idea does not appear to have been followed up.

Spark-throwing and a noisy exhaust are being overcome by compounding the cylinders, but the smoke question is as far from a practical solution as ever. Coke or anthracite can be used in steam rollers, as their work is very light in comparison with their power; but either fuel is much too slow in combustion for road engines working with a remunerative load.

In further reply to your correspondent, Mr. Robert Phillips, it is a pleasure to see that he does not include "the little, harmless thrashing engine" in his list of evil-doers, as it is with this class of engine I am chiefly interested. His personal remarks I will let pass for what they are worth. Personalities are out of place in a correspondence of this kind. Mr. Phillips asks why a farmer should be exempt from licence when sending his barley out with his own engine. Why, in the name of common-sense, should he be liable to pay a licence, any more than his neighbour who carts his corn out with his horses? Engine owners require no special privileges. They only ask for equal treatment with other persons using the highways, and while they pay rates and taxes they have a right to demand it. Certificates for drivers is a question which will be settled by Parliament in the near future, and will then include not only traction engine-men, but persons in charge of any kind of steam boiler.

AN AGRICULTURAL ENGINE OWNER.

Norwich, November 26th.

SIR,—The description of a traction engine in your article on page 449 in your last issue is, unfortunately, so very true as to be easily confirmed by most people. At the same time, this kind of thing is not to be mended by such action as is proposed to be taken by the Great Western Railway Co. in its bye-laws, nor yet by any other measure which aims at squashing the traction engine altogether.

There is nothing more certain than that the traction engine in some form or other has come to stay, and it is in not recognising this fact, or trying to blink it, that road authorities and others are continually getting "off the track." They might just as well have tried to stand still when wheel carriages and wagons were first introduced, and claimed that the roads as they then were, were good enough for the ordinary pack-horse and foot traffic, and therefore wheeled abominations should not be allowed to come in and cut the footpaths up. The clock will not stand still any more for surveyors whose idea of keeping up roads is to keep everything objectionable off them, than it will for those drivers of half-broken horses which cannot be got to pass a bicycle without a lot of dancing about, or the owners of bridges which should have been rebuilt long ago.

It is of no use whatever to propose or suggest absurd regulations, which, on the very face of them, have no other aim than that of choking off the traffic altogether. Harassing regulations simply set men's backs up, with the feeling that they are to be cleared out to suit the purpose of some big corporation, or because some surveyors fancy that it will please their "powers that be" to be continually worrying the engine-owner. Unfortunately, the traction engine drivers, and their owners as well, are very often a rough and uncultivated set of men; but it has yet to be shown that there is anything so very seriously wrong with the traction engine and the work it does as to require such a drastic measure as practically snuffing out completely.

Taking engines in their present form, I think it is quite safe to say that the majority of men employed in driving them are not fit for their work in any way; very many of them are ignorant, dirty, and careless beyond measure; absolutely mannerless; and by their own condition, and that in which they quickly get an engine, they raise a feeling of dislike against themselves and their charge long before they even get a chance of making themselves more actively objectionable. As a maker of traction engines it has sometimes gone to my heart to see a fine new engine, upon which we have done our best, and for which the owner has paid hundreds of pounds, handed over to some ignorant clod-poll, whose qualifications as a driver are that he knows there is a hole in one end where the coal goes in, and one at the other where the smoke comes out, and a handle at the top, by pulling which he can start the engine.

Often the same engines will be brought back within six months a perfect wreck, the owner disgusted, and the driver ready for another. I can quite understand, and indeed have often been a witness, that during the period that the wrecking process was going on, the driver had managed to make himself objectionable to a good many people on the road. For this, however, I do not think the design of the engine is so much to blame, and some simple regulations, which ruled the selection of drivers, would put an end to the most of it. On the other hand, I could give scores of instances where traction engines are passing through towns all day without giving any offence whatever; and it was only the other day that I saw an engine, with three loaded trucks, pass through the busiest part of the city of Aberdeen, down to the docks; showing only a very slight vapour of steam from the chimney and no smoke, and not a single horse or individual seemed to take any notice of it, although it was the busiest time of the day.

The simple reason was, that the man who drove it knew his business, and had his engine in good order. The noise of the exhaust, smell of bad oil, and the wholesale splashing of it about, at which Mr. Phillips reasonably enough takes objection, were also conspicuous by their absence. With regard to the question of the condition of roads, and the endeavour to freeze traction engines out under the excuse that they are outside the ordinary requirements of the traffic of the district, this will never be settled until it is understood and agreed that traction engine traffic properly conducted is ordinary to any public road, and is as free to come and go as anything else on wheels. To maintain otherwise is, as I have said, merely trying to stop the clock. The conditions of life and business are continually changing and developing in one direction or another, and it is impossible to allow authorities to stop the development of traffic, simply because some roads which they do not want to repair properly were made to suit other times.

It is not more than forty years since hauling engines first began to work. Yet in the county of Kent, where there is more traction engine traffic than in any other part of the country, one hears infinitely less fuss made about the damage done to roads than in some other districts where engines are far fewer, for the simple reason that the authorities have not tried to stop the clock, but just made up their roads to the traffic. And where will you find better roads? To anyone who understands the outs and ins of the whole subject, this complaint of "extraordinary traffic" seems the paltriest kind of contention, and is so obviously brought forward for a motive that it is impossible to argue seriously against it on its merits.

This is the kind of thing: In a county pretty well known as having about the worst roads in England, the authorities, or their surveyor, consider that the proper way to keep a road is every now and then to put a thick layer of chalk on it, and then cover the latter with broken flints. As long as the weather is dry the only thing that happens is that the flints very quickly grind into powder, and the traffic flattens the crown of the road; but as soon as the rain sets in the chalk and flints grind up into a paste which holds water like clay puddle, and then the condition of things is simply abominable for everything that comes that way. It does not require a traction engine to do this kind of road any harm—the harm has all been done by the authorities, and every ordinarily loaded farmer's wagon or dray that goes over it will cut down into it like cutting into dough.

It is only these roads, and others like them, that are the cause of contention; and the truth about them is that the authorities who make them are even less fitted for their work than are the roads for the ordinary traffic of the district, or indeed any traffic at all. Yet if you speak to any of the powers that be about them, you are met at once by the whole stock of arguments that came out and flourished round at the time the toll-gates were done away with.

With regard to the weight of traction engines being excessive, it seems to me that after all this must be more or less comparative. It is idle to say a traction engine is bad because it is heavy, and an ordinary agricultural wagon is not bad although it is heavy. There should be a standard of weight per unit of breadth of wheel agreed to, irrespective of whether the wheel belongs to a traction engine or anything else. A very common type of agricultural engine used for threshing weighs about 10½ tons. This weight is carried by four wheels, the two hind ones being each 16in. to 18in. wide, and the two front ones 8in. to 9in. wide. Now, assuming that two-thirds of the whole weight comes on the hind wheels, we have 7 tons on, say, 32in. of width of hind wheel, and 3½ tons on 16in. of width of front wheel. Compare this with an ordinary four-wheeled wagon weighing 30 cwt., with 5in. tires, and carrying a load of, say, 3 to 3½ tons. There is practically no difference in weight per unit of width of wheel, and in many cases traction engines have wheels 18in. to 22in. wide, with the object of reducing this weight per unit of width.

There is, of course, the objection of cross plates on the traction engine wheel, and the fact also that the power of the engine is exerted through them on the roads; but this is to be set off by the much larger diameter of the wheels, and the fact that even when the weight per unit of width is the same as in the narrow wagon wheels, the broad wheel has a much better chance on the surface of an ordinary road; and it may be seen any day that, on a decent road, the cross plates of a traction wheel makes no worse mark than the rut of a cart wheel.

With regard to the matter of bridges, the contention that traction engines are too heavy because some bridges are feared to be too weak, will have to go with the "extraordinary traffic" idea; the bridges have probably served their purpose very well, and the sooner they are removed to make room for something stronger the better. As far as engines which are intended to haul wagons along the public roads are concerned, there is no reason why they should not be made much lighter in weight than they usually are at present, beyond the fact that they are practically built to meet the present regulations, which requires a man to walk in front of them.

As, however, you have already in your article dealt more effectively with this point than I can attempt to do, I will say no more about it—except that I would like to point out that there must always be a distinction made between engines which are used solely for threshing purposes, and which go about from farm to farm hauling their threshing tackle, and those engines which are used for road hauling only. Although the latter are usually the heaviest class, they might easily be made the lightest if they were allowed to travel faster with lighter loads; and as they are the ones which come in contact with people who use the roads with horses and carriages, they should be made so as not to give any offence by steam or smoke, or those heartrending, ear-splitting noises which at present very often make life unbearable to any ordinarily educated horse or individual.

With regard to the self-moving threshing engine, I do not see that it is possible to get a satisfactory engine on much less than the present weight, as the conditions are so totally different from hauling a load on a good hard road.

A threshing engine has to take its machine, and probably a straw elevator or a baling machine, to some point among fields, with no road at all, and perhaps a filled-up watercourse or two to cross by the way.

I know a case which occurred not long ago, of an engine on a journey like this, in which, with a pair of 22in. wheels, got so far into the ground at a place where a diverted watercourse had been filled up, that the top of the hind part of the tender sunk to within 5in. of the ordinary surface level of the ground. It may seem paradoxical, but in a case like this a light engine is of no use at all.

The engine in question got out without help, but a light engine would have had to be lifted out. It may perhaps be said that a light engine would probably not have got into the mud so far, and neither would it; but the light engine would never have got into a field at all with its machinery. The standard which all these engines must be built up to is the stress of starting themselves out of a hole with full steam pressure, and very often a good deal more, and nothing but weight will give the required strength. This class of engine also suffers from the prevailing agricultural depression, and generally gets into the condition noticed by you, by being driven by the cheapest, or rather the lowest-priced, labour that can be got to stop on the job. However, as long as farmers grow corn they must have it threshed, and the only thing is to regulate the management of their engines in some reasonable way, without making an already hard life still harder for him. Unfortunately, traction engines are owned by men who are not very well able to express their views or feelings, and are consequently very much at the mercy of the fancies or prejudices of individuals whose only wish is to see him out of the way altogether.

What can one expect from a bench of magistrates who unanimously mulct a traction engine owner in damages for cutting a road up, although it was proved that before the traction engine ever went on the road, at certain seasons of the year a loaded farmer's wagon would sink in up to the axles in those same places, which were said to have been cut up by the traction engine. There surely cannot be any serious difficulty in framing a set of regulations which shall have the effect of keeping the traction engine traffic from being harmful or dangerous, if the matter is only gone about in a reasonable way, and not by one side with the determination to suppress the other side altogether.

Although I am prepared to argue that in many cases the present weights of engines cannot be much reduced, yet I quite recognise the fact that in a great many cases something can be done, and also that there must be a limit somewhere, and I would suggest that this ought to be calculated on the basis of some settled weight per unit of width of driving wheel, something similar to what is aimed at in the present Act, but which is not properly arranged or carried out.

In order to meet the case of heavy ploughing and agricultural engines, and at the same time to prevent road engines being made of excessive weight, I would propose, instead of limiting the weight of any class of engine, to limit the load allowed behind any one engine to 12 tons or 15 tons gross weight, do away with the man in the front, and allow speeds of eight or ten or even twelve miles per hour. There would then be no inducement to build heavy slow-moving engines, and I don't think it would be long before a much better type than the present engine would be seen on the road.

The questions of springs, spring and india-rubber wheels, and, indeed, everything else about the construction of the engine, would soon readjust themselves. There certainly ought also to be further regulations as to the qualifications of drivers, proper covering up of working parts, blowing off of steam and smoke, and observances of certain rules of the road. On the other hand, the present harassing system of licensing ought to be done away with, and wider limits of working hours allowed.

In addition there should also be some regulation requiring efficient brakes to be fitted on both engine and wagons. It is too much, perhaps, to expect that any set of laws would satisfy every person, but I would contend that regulations framed in a reasonable spirit, and based upon those points which I have suggested, would allow traction engine traffic to live and progress without harming any person, place, or thing; and this, I take it, is the aim of all ordinary minded people who are willing to live and let live.

November 26th.

## THEORY OF THE STEAM ENGINE.

SIR,—Before this discussion closes I should like to say a few plain words to strengthen the faith of such of your readers as are too apt to conclude, from such letters as have appeared in your correspondence, that there is something doubtful or uncertain about the accuracy of the modern theory of heat engines as expounded by such men as Rankine and Clausius. It is to this point that I have intended my previous short letters to lead. That Rankine made grave errors in his application of the general theory to concrete examples such as are met with in actual practice, I have repeatedly asserted and demonstrated in articles written for the provincial press, and I think also in your own correspondence columns. This does not, however, affect the accuracy of the laws themselves. It merely evidences the necessity of the practical engineer discriminating between the intrinsic truth of such laws, and their judicious application to the critical examination of the results actually realised or anticipated.

Also it may be remarked that in the case of the steam engine we do not need to take into consideration the theory of thermodynamics in its utmost generality, but may limit our examination to the application of the general laws to engines, in which the working substance is a more or less imperfectly gaseous body in contact or otherwise with the liquid form of that body. Heat is communicated to the body chiefly in general when in its liquid state, and rejected (to use Rankine's expression) when the body is in a more or less attenuated condition. The varying pressure of the working body on a piston, or some mechanical equivalent, is caused by suitable mechanism to result in the conversion of heat into mechanical work.

Now, what Carnot's, Rankine's, and Clausius' investigations teach irrefragably is, primarily, that under such circumstances the maximum fraction of the whole heat expended, which cannot be converted into mechanical work by the pressure of the working substance over the piston, cannot possibly exceed $\frac{T - t}{T}$. The maximum absolute temperature at which heat can be communicated to the substance being T, and the minimum absolute temperature at which heat can be rejected being $t$. It is not open for anyone to attempt to cloud the matter by vague surmises as to air, &c., having essentially different laws of action from steam when employed as a working substance, steam, whether saturated or otherwise, being as much an imperfect gas as air or carbonic anhydride or any substance, so far as we at present know, capable of existing in a gaseous condition.

It is also much beside the question to direct attention to the behaviour of solid bodies not acting cyclically as the working substances, receiving and rejecting heat. Again, a certain class of inventor has endeavoured to unsettle the minds of those who lack time to weigh the matter, or, possibly, have never acquired the mathematical habit of thought necessary. This class of writer and those who follow in his steps seeks to minimise the possible maximum efficiency of the heat engine, and asserts that the fraction $\frac{T - t}{T}$ is not to be taken as a datum of reference for the economy of engines which have hitherto been actually constructed.

From my point of view this is a frivolous contention. It is not a question as to whether the efficiency $\frac{T - t}{T}$ has been or can be realised under the conditions obtaining with the modes of working which have hitherto been found possible. The true question is whether this efficiency can be *exceeded* even theoretically. Practical experience and mathematical investigation alike reply in the negative. In applying the theory to the cases of engines actually realised mechanically in practice, we meet, of course, with the usual difficulties resulting from the attempt to apply conditions consistent with the attainment of maximum efficiency, to imperfect mechanism, which, under the most favourable conceivable circumstances, can only attain a fraction of that efficiency.

Thus, in the case of the steam, gas, or other similar engine, the available heat is not received by the working substance at a definite temperature T, but at varying temperatures, which can only be cognised, in most cases, with impracticable difficulty. Neither, on the other hand, is the unutilised heat, rejected at a single definite temperature $t$. Another class of writer further unsettles the ideas of the uninitiated by disputing the title of Carnot's ideal engine to be treated as specially perfect and reversible. Now I have pointed out above sufficient reason for terming Carnot's engine, in a certain sense, perfect, since its efficiency cannot be exceeded by any heat engine as yet made or suggested. Also it is reversible in the sense that it may be used either to convert heat into mechanical work when the passage of heat takes place from a hotter to a colder body, or *vice versâ*, it may be used to cause the passage of heat from a colder to a hotter body at the expense of mechanical work.

Again, as regards its claim to be treated as the typical "perfect and reversible" heat engine, there should not need much discussion if verbal hair-splitting is avoided. Carnot's engine is that originally conceived by him for the purpose of demonstrating the law of maximum efficiency. Also the simplicity and ready comprehensibility of the conception; all unnecessary adjuncts, such as regenerators, being, as it were, pruned from the engine, do in themselves render it appropriate to treat it as the specially typical perfect and reversible engine. It is perfectly open for anyone that feels so inclined to emphasise the fact that other ideal engines can be conceived of equal efficiency with that generally known as Carnot's. This should not, however, be done in such a manner as to unsettle the minds of untrained thinkers by leading them to suppose that this fact militates against the theory of thermodynamics or the law of maximum efficiency.

HENRY CHERRY.

## A PROBLEM IN VIBRATION.

SIR,—Kindly allow me space in your columns to ask a question on a problem, which no doubt some of your readers can solve. The accompanying diagram is an apparatus composed of two pieces of cardboard, joined by two or three light strips of the same material, with a rod passing through both pieces, which can be placed in any of the positions $a\ a_1$, $b\ b_1$, or $c\ c_1$, thus shifting the position of the centre of gravity. For the position $a\ a_1$, the combined centre of gravity for the whole apparatus is 6in. from the apex; for the position $b\ b_1$, the centre of gravity is 8¾in.; and for the position $c\ c_1$, the centre of gravity is 11½in. from the apex. The position of the centre of gravity of the cardboard alone is 5⅝in. from G, when at rest.

The problem is, to find how many vibrations would be made per minute when rocking, supposing the rod to be placed in the several positions given. The weight of the rod is 7½ oz., and the weight of the cardboard 5 oz. By experiment I find the vibrations with rod at $a\ a_1$, approximately 84 per minute; at $b\ b_1$, approximately 130 per minute; and at $c\ c_1$, approximately 210 per minute; but I am unable to find any formula which will give me even an approximation to the experimental results. Surely there must be some mathematical method of determining this. I have had a suggestion that the formula for the time of roll of a ship is attained by a formula that fits this case; but, does not the fact of the metacentric height being constant overthrow this?

McHINERY.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*⁂ In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*⁂ We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*⁂ All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

P. R. (St. Andrews).—*Your solution is not correct. The opposite movement occurs.*

J. A.—*We published the Great Western Railway Company's circular last Friday.*

Messrs. H. and Co.—*Messrs. Elordi and Esteves' report has not been printed in* The Engineer.

M. O.—*You can make any use you please of the printed specifications sold by the Patent-office without communicating with the patentees or anyone else. They are specially published to supply the public with information.*

C. Z. S.—*We have no recollection of the precise question to which your letter refers. We fancy that it originally referred to a statement that but for its weight, which must not be confounded with its mass, an electric cable surrounding the earth would be broken by centrifugal force.*

### AIR PROPELLERS.

(*To the Editor of The Engineer.*)

Sir,—What is the best shape, angle, number and arrangement of blades for a propeller acting on the air, to give the greatest thrust?

November 29th. A. R.

### TAR PAVING MACHINERY.

(*To the Editor of The Engineer.*)

Sir,—I shall be much obliged to any of your readers for information respecting tar paving mixing machinery and sewer trench machinery as used in America.

City Engineer.

November 29th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*⁂ The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

The Institution of Civil Engineers. — Tuesday, December 4th, at 8 p.m. Papers: "The Machinery of Warships," by Mr. Albert J. Durston, Engineer-in-Chief of the Navy; "Colliery Surface Works," by Mr. Edw. B. Wain, Assoc. M. Inst. C.E. Friday, November 30th, at 8 p.m. Students' meeting. Paper: "Sub-aqueous Excavation at Newry," by Mr. Charles H. Olley, Stud. Inst C.E. Mr. J. Wolfe Barry, C.B., member of Council, will take the chair.

The Institution of Junior Engineers.—Friday, December 7th, at Westminster Palace Hotel, Victoria-street, at 8 p.m. Paper: "Waterworks and Appliances," by Mr. William Mallock, of the Grand Junction Waterworks, Hampton.

North of England Institute of Mining and Mechanical Engineers.—Saturday, December 8th, at the Wood Memorial Hall, Newcastle-on-Tyne, at 2 p.m. Paper: "The Cost of Electric Transmission of Power," by Alexander Siemens, President of the Institute of Electrical Engineers.

Royal Statistical Society.—Tuesday, December 4th, at the Lecture Theatre of the Museum of Practical Geology, 28, Jermyn-street, S.W., at 4 45 p.m. Paper: "The Eleventh United States Census," by Hon. Robert P. Porter, and an exhibition of the Hollerith electrical counting machine.

Geologists' Association.—Friday, December 7th, at University College, Gower-street, at 8 p.m. Papers: "Note on Megalosaurian Teeth, Discovered by Mr. J. Alstone in the Portlandian of Aylesbury," by A. Smith Woodward, F.Z.S; "On the Geology of the St. Gothard Pass," by H. W. Monckton, F.G.S.

Society of Arts.—Monday, December 3rd, at 8 p.m. Cantor Lectures: "Modern Developments in Explosives," by Prof. Vivian B. Lewes. Wednesday, December 5th, at 8 p.m. Paper: "Fire Protection," by Edwin O. Sachs. Thursday, December 6th, at the Imperial Institute, at 4.30 p.m. Paper: "Roman and British Indian Systems of Government," by Hon. W. Lee-Warner, C.S.I.

### DEATH.

On November 26th, at Ivy Court, Tenterden, Kent, Francis Jellanus Dennys, M.I.C.E., J.P., eldest son of the late Commander Lardner Dennys, R N., aged 66.

# THE ENGINEER.

*NOVEMBER* 30, 1894.

## FLAMELESS EXPLOSIVES.

The recent appearance of a report on flameless explosives from a Committee of the North of England Institute of Mining and Mechanical Engineers revives memories of notes made in The Engineer, May 24th, 1889, page 443, after the appearance of the report of the French Commission on the same subject. It was then demonstrated that powder under any circumstances was unfit for use in firing mines, that nitro-glycerine mixtures were to be regarded with suspicion, and that the only mixtures more or less attaining the standard of safety then and now set forth were certain ammonium nitrate compounds; but it was pointed out that the drawback to such mixtures was that the admixture of their constituents was never absolutely intimate, and explained irregularities then observed in the results obtained with those mixtures. The Commission formulated the following rule, which does not seem to stand in need of much alteration at the present day: "On account of the complexity and uncertainty of the phenomena which may be produced by detonation in the open air, it will always be prudent to avoid firing a shot in mines at those places where the mixture of air and marsh gas is inflammable, even when the explosive employed is one of those considered most safe. The choice of this explosive ought to be regarded as diminishing the danger of explosion considerably, but not as suppressing it absolutely." They also observed that the best effects and the most certain results were obtained when the explosive was completely detonated, which occurred when the explosion was confined; they therefore attached great importance to ramming the charge well into the borehole, and in addition tamping well. Moreover, they regarded as dangerous the use of high explosives in small and more or less confined areas, for under such circumstances the rapid dilution of the products of explosion with air, so essential to safety, might be impossible.

Turning now to our own country, it is known that the restrictions imposed on the use of explosives in mines by the Coal Mines Regulation Act, 1887, rendered imperative the employment of explosives which would not ignite gas or coal dust, and this led to the invention and introduction of several so-called flameless explosives—or, in other words, explosives which ought to detonate at a temperature below the ignition point of an explosive mixture of fire-damp and air, and to yield, when detonated, no combustible products. It was soon found, however, that the flameless explosives placed at the disposal of the miner did not fulfil these conditions; and therefore the inquiry, which originated the subject of the most recent British report, was instituted with the object of clearing away doubts and uncertainties connected with the employment of safety explosives in mines.

We have already, on September 14th, had occasion to mention these investigations, when certain experiments were performed in the presence of some members of the Federated Institution of Mining Engineers, at the works and with the apparatus that are in the report described in detail, with illustrations. Now that more particulars have been made public, it may be well to recall here the appliances used by the committee:—The experimental chamber consisted of a cylindrical tube, 101ft. long by 3ft. in diameter, made of ¼in. Tudhoe wrought iron plates, rivetted with Low Moor iron rivets, constructed in tubular sections, each made of seven plates and bolted together by means of angle-irons riveted on to each end of each section. Glazed sight-holes were arranged at appropriate intervals along one side of the cylinder, whilst the top was furnished with ten vents, 4in. in diameter, 10ft. apart, and fitted with hardwood plugs. One end of the cylinder was closed by a wrought iron plate bolted on to the end angle iron and having in the centre a hole 16in. in diameter, which would be blocked by the cannon in an experiment, whilst 22½ft. from this end a sheet of brown paper, rendered air-tight by varnishing and cut to the required size, being placed against the angle iron and held in position by an iron ring bolted on, acted as a diaphragm to isolate the part of the cylinder used as a combustion chamber for holding the gaseous mixtures from the remaining part of the cylinder, the far end of which was also loosely covered with brown paper before an experiment, to keep out light. The cannon for holding and firing the explosives was a cylindrical steel block —hooped with five steel rings—4ft. 6in. long, and 18in. in diameter at the breech, and for 18½in. from it, the diameter of the remaining length being 15¾in.; the bore was 42¼in. long and 1⅓in. in diameter, and was drilled out of the solid block. The cannon was mounted on a carriage fitted with three pairs of wheels running on rails, and so could be made to approach or recede from the closed end of the cylinder. When experimenting the joint between the cannon and the cylinder was made tight by an india-rubber ring and puddled clay. The necessary pipes and stop-cocks were fixed to connect the combustion chamber with the external air; with a gasometer for delivering a measured quantity of gas into the cylinder, with a Schiele fan, 24in. in diameter, for mixing the air and gas, and operated by a 3-horse power Tangye gas engine, and with a heating arrangement. The combustion chamber was, moreover, provided with a water gauge, and air vent with a stop-cock, and three apertures for abstracting samples of gas. Generally a simple estimation of the oxygen in the mixture by absorption with alkaline ferrous tartrate, and allowing for a small amount of oxygen and carbon dioxide present in the combustible gas employed, supplied sufficient data for calculating within 0·5 per cent. the percentage of explosive gas present.

The operations involved in an experiment were—displacing the existing atmosphere by ordinary air, fixing the brown paper diaphragm, charging and adjusting the cannon, closing the top vents, opening the necessary stop-cocks to admit the desired proportion of gas, and allow a corresponding volume of air to escape through the special vent, closing these stop-cocks and opening those connecting with the fan, mixing, closing all stop-cocks, taking samples and temperatures of mixed gases and firing the shot. If flame effects were to be observed, observers would have been stationed in and taking observations from an adjoining dark-room, the parting brick walls having holes in it corresponding with the glazed ports already referred to, whilst other effects could be recorded in the cylinder room or in the open air. It should be noted that the brown paper would not inflame readily, and that glowing brown paper is not capable of igniting explosive mixtures of gas and air. Of course, samples of the gas could be taken after an explosion, though perhaps the character of the actual atmosphere might be disturbed by inrushes of the external air from the top vents, which would be frequently forced out by the explosion, or from the opening caused by recoil of the cannon or by wind blowing in at the other end.

The explosives used in these experiments were obtained from local collieries, and their relative strengths, tested by the Trauzel method in lead blocks and fired unconfined, were bellite 100, securite 98·13, ammonite 88·73, roburite 80·94, carbonite 41·24, Ardeer powder 26·90; and on this basis the weights employed for shots of each explosive were 1 oz. each bellite and securite, 1⅛ oz. ammonite, 1¼ oz. roburite, 2½ oz. carbonite, 2¾ oz. Ardeer powder—quantities less than those used in a mine. Experiments were made with stemmed and unstemmed shots fired into air, into explosive mixtures of air and coal gas, and of pit gas and air. Bellite unstemmed gave a flame several feet long in air with or without coal gas up to 6 per cent.; with 8 per cent. it caused ignition. With fire-damp 11·6 per cent., and air it frequently gave a flame but caused no ignition. Stemmed it frequently coused ignition with mixtures containing 8 or 10 per cent. of coal-gas, but not with those containing 10 or 11·6 per cent. of fire-damp. Securite behaved in a similar manner to bellite, but in addition, when not stemmed caused ignition of mixture containing 11·6 per cent. of fire-damp. Ammonite behaved somewhat similarly to securite, but gave longer flames. Roburite resembles to some extent bellite, but ignited, when unstemmed, the 6 per cent. coal-gas mixture. Carburite, unstemmed, gave shorter flames than the preceding explosives with air alone, and 4 and 6 per cent. coal-gas mixtures occasionally ignited an 8 per cent. mixture; but neither ignited or scarcely gave a flame in the 11·6 per cent. fire-damp mixture, whilst when stemmed it only occasionally ignited an 8 per cent. coal-gas mixture, and not at all an 11·6 per cent. fire-damp mixture. Ardeer powder, unstemmed, also gave comparatively short flames, but behaved irregularly, sometimes giving a flame, sometimes not, sometimes igniting an 8 or 10 per cent. coal-gas or an 11·6 per cent. marsh-gas mixture, and sometimes not only not igniting but not even giving a flame. Stemmed, it occasionally ignited 8 or 10 per cent. coal-gas mixture, but not at all 10 or 11·6 per cent. fire-damp mixtures. For stemming damp puddled clay rolled into cylinders of 1in. to 3in. were employed; the difference in depth of the stemming did not seem to exert any important influence on the result. Incomplete detonation was observed, both in stemmed and unstemmed cases, and has, of course, given rise to irregularities, but did not render nitrate of ammonium explosives more capable of igniting inflammable gaseous mixtures, as the French Commission reported. With regard to the effect of detonators alone, it has been found that mixtures of both coal-gas and air and fire-damp and air have been ignited by detonators containing 15·4 grains of fulminate of mercury—which, too, is at variance with the result recorded by the French Commission. In the present case, too, the fire-damp seemed more susceptible to the detonator shock than did the coal-gas. No experiments were made with water-cartridges, because the bore in the cannon was not large enough. It is curious that there is generally a perceptible interval after the firing of the shot, before the ignition of the gas takes place. The ignition varied in violence, as might be supposed, according to the position at which it took place in the combustion chamber, being more violent if it started near the cannon than if started near the diaphragm.

That these experiments have been conducted with considerable skill, care, and deliberation, there can be no doubt; and it is therefore of interest to make special note of the conclusions arrived at, which briefly are as follow: All the high explosives on detonation produce evident flame, but they are less liable than blasting powder to ignite inflammable mixtures of air and fire-damp, nevertheless cannot be relied on as ensuring absolute safety, therefore must be regarded as only lessening and not abolishing the risk of explosion. It is consequently essential that similar examinations of the working places, and precautions which are in force in mines where blasting-powder is used, should be rigidly observed when high explosives are employed. If a charge of high explosive has missed fire, and short lengths up to 8in. of stemming have been employed, it may be detonated by another cartridge of the explosive and additional stemming placed in the hole in front of the original stemming. These explosives are found to be defective as regards admixture, variable as regards proportions of the ingredients used in their manufacture, and they alter in character with age. These latter facts are advanced to account in some measure for the irregularity of the results following upon the detonation of these high explosives.

The present investigators do not find tamping or stemming will be absolutely trustworthy for obtaining the best result from the explosive, nor do they comment on the advisability of restricting the quantity of explosive used in a small area to an amount not capable of yielding a volume of gas that would approach that of the surrounding atmosphere. With these two exceptions, we cannot but be struck with the agreement between the results now obtained and those mentioned at the commencement of this article; and while it is without doubt satisfactory to see such confirmation by different investigators in these vital matters, we cannot regard with equal satisfaction the fact that, judging from this most recent report, little or no progress has been made in this direction during the last six years, and that a certain grim uncertainty still surrounds the problem of how to win coal safely and cheaply from fiery mines.

## LOCOMOTIVES AND TRAINS.

THE correspondence which appears in our pages, dealing as it does with many subjects connected with the conduct of railway traffic and the performance of locomotive engines—ancient and modern—would have been yet more interesting than it is had the locomotive superintendent, the traffic manager, or the engine driver taken part in it. Obviously it has flowed from the brains and the pens of more or less shrewd and well-informed amateurs. We use the title in no invidious sense; and we would indeed insist on the fact that the amateur, if only he is careful, may be of use by presenting facts in a new light to professional men. There is no doubt a tendency in all professional men to fall into grooves of thought and practice; and it does them good perhaps to be told from time to time that the world is not quite what it seems to them to be; that other eyes see it not as they do, and that other brains think about it in a different fashion. While, however, we concede so much to the gentlemen who, taking the Northallerton accident for a text, have said so much in our pages in the way of criticism on the management of our great railways, it will not be out of place if we call their attention to certain facts which they have either forgotten for the time, never knew, or of which they underrate the importance. Let us in a word consider some of the questions raised, from the point of view of the traffic manager, the locomotive superintendent, and the engine driver. Certain of our correspondents, it will be remembered, assert, first, that to take a pilot or second engine is a costly mistake. Others complain that the modern locomotive is too big and heavy, and that all that it can accomplish has been done as well, or better, by much smaller and lighter locomotives. Brief as is this statement, it will be seen that it covers portentous issues. Enough to fill a volume might be written on the subject. We may be excused if we leave much unsaid that might be said with advantage.

The traffic manager looks with no special favour on heavy rolling stock; but he has to provide it notwithstanding. It is a result of competition on the one hand, and of the prevailing desire for comfort and even luxury on the other hand. Not twenty-five years ago, passenger coaches on most of our railways were carried on four wheels, and weighed eight to nine tons. They may still be met with on some branch lines. A dozen years ago they were found on the main line of the London and Brighton Railway. They were so low that a moderately tall man could not stand upright in them. They were narrow and cramped and comfortless, but they were very light. The proportion of dead weight to paying load was comparatively small. The northern traffic of the kingdom has, however, been made the principal subject of discussion by our correspondents, and it will be well to confine our attention to it. There are three great railway systems competing for it—the West Coast, the Midland, and the East Coast. The railway companies, some six or seven in number, concerned, have continually outbid each other, until in no other country under the sun is such fast and luxurious means of travel provided. The passenger coaches have increased in weight from eight to seventeen, twenty, twenty-five, and even thirty tons—and this, be it remembered, while the number of passengers per coach has been but little augmented. The dead weight as compared with the live or paying load is enormous. This palatial rolling stock has not been adopted as a matter of choice. The travelling public will have it, and they get it. If the railways were worked by Government the public would enjoy no such benefits, and that is one reason why State railways are a mistake. The traffic managers must not be blamed. They must not be told that they are using stock too heavy, too expensive, too unwieldy. We do not suppose that any traffic manager in the kingdom thinks otherwise in his secret heart. But the public demand corridor trains, dining cars, Pullman drawing-rooms, sleeping berths, &c.—and what the public demands it gets. If our readers see anything wrong in this direction in modern rolling stock they must blame the public.

The locomotive superintendent finds this heavy stock made up into long trains, and he is told that they must be hauled at very high speeds and with the greatest conceivable punctuality. Now, he has long since found out that the work of hauling is a very variable affair. It is one thing on a fine summer's day. It is quite another in a storm of rain and wind. He knows that however well a light engine can perform over a stretch of level road, there is a bank somewhere to be climbed, and the result is that he has to design and build locomotives which, while too powerful for light trains and fine weather, are taxed to the utmost on steep roads in winter. Very naturally he builds a big, powerful engine. To this our correspondents take exception. Because the little London and North-Western engine Waverley hauled a train of 80 tons to Crewe at some 56 miles an hour the whole way during fine summer weather, it seems to be argued that a somewhat similar class of engine ought to be able to conduct the entire passenger traffic of the London and North-Western between Euston and Crewe. It is only necessary to state the matter in this way to show how absurd is this contention. Some of our readers, however, are willing to admit that a more powerful engine is needed to draw modern rolling stock than that which sufficed hitherto, but they object to the extra weight. In a word they contend that the engines are too heavy for their power. We have here an admirable instance of the amateur method of reasoning. A locomotive is constructed to draw trains. Every ounce of weight hauled represents so much fuel; all the weight possible ought therefore to be saved. This reasoning is quite perfect in its way; but the locomotive superintendent knows what the amateur does not, namely, that the cost of fuel is comparatively a small item in working a railway, and that a matter of very much more importance than a little saving in coal is the cost and demurrage of repairs. If we take a modern locomotive with 1000ft. or 1200ft. of heating surface, and compare it with one of the same boiler power built ten years ago, it will be found that the latter is some tons heavier. It will, for example, have a bogie which adds at least three tons. The boiler pressure will be greater, and the boiler much more strongly stayed. The frame plates will be thicker and deeper; the axles larger; the tires 3in. thick instead of 2½in. All the bearings will be larger and wider and longer, and so on. The whole machine will be much heavier and more massive. All this represents some five or six tons difference between the new and the old engine; but the consequence is that the new engine costs next to nothing for repairs for long periods of time. Breakdowns are practically unknown. The engine is always ready when wanted. It will run for years without more repairs than are represented by the turning of the driving and leading wheel tires. Only those who have had experience can realise the difference between a heavy engine and a light engine of the same power as regards repairs; and the curious feature of the matter is, that if we turn to the coal bills it will be found that the modern heavy engine is burning less coal per train mile than its light predecessor. It would involve a considerable digression to explain why. Our readers must be content to accept the statement that, notwithstanding the great augmentation in the weight of rolling stock which has taken place of late years, no tantamount increase has taken place in the consumption of fuel per train mile. This admirable result is due to a number of causes, such as increased boiler pressure and better permanent way—matters which we shall not stop to consider. Thus, then, it will be seen that there is really method in the madness of both the traffic manager and the locomotive superintendent.

What has the engine driver to say on the subject? He at all events has nothing but praise for the big, heavy engine. He knows by experience what it is on a winter's night with a long train to have a locomotive thoroughly up to its work. He knows the heart-breaking, soul-depressing struggle that takes place when he has a locomotive taxed to the very utmost to push along as best he and his fireman can; when he dare not put on an injector unless he is running down hill; when the difference between ruin and comparative success depends on the consummate skill of his fireman and good luck with his coal. Only those who have stood on the foot-plate of a locomotive charged with a big express train on a winter's night can understand what the driver's and fireman's work really is, and the difference to them of the two classes of engine. Concerning the question of pilots, about which so much has been said, we have already written pretty fully in another impression. The evidence given at the close of the inquiry into the Northallerton accident throws a good deal of light into places where it is much wanted. The evidence of the injured driver has at last been taken. It will be remembered that the action of the railway company in giving him a pilot from Darlington to York has been sharply criticised. His explanation goes to the root of the matter. He took a pilot because his Westinghouse air brake compressing engine was out of order, and working badly, "the piston sticking," and also because his engine was steaming badly. As regards the first point, it is obvious that if he had proceeded with his air brake in a condition of doubtful efficiency, he would have incurred a very serious responsibility. For this reason alone he was bound to take a pilot engine, on which the Westinghouse compressing engine was working properly. As to his second statement, we fear that it will be difficult to make its purport intelligible to an outsider, while everyone who has fired or driven a locomotive will understand it at once. The steaming power of a boiler depends on the fire. Now it is the easiest thing imaginable to get a fire either in a locomotive or, for the matter of that in an ironworks, into bad order, and once that occurs things go from bad to worse. Thus, for example, a locomotive starts with a heavy train on a "green" fire. That is to say, there is much coal in the fire-box not yet ignited. Steam is blowing off. It is then a toss up whether the pressure will be lost, or the fire will burn through in the first couple of miles. If the latter, all will go well; if the former, unless it is a stopping train, or there is a long bank to run down, the case is probably hopeless. We have known an express train lose forty minutes in a run of forty miles in this way; and when stopped by signal outside an important junction, the engine was unable to start again, for want of steam, for nearly five minutes. It may be said that in the Northallerton case the driver could have got his fire right between Darlington and York. That would have been impossible. Or that he should have taken his engine off and left another to go on. That avails nothing, as the engine had to go to York in the first place; and he would have disobeyed orders had he not gone on, in the second place.

We have, of course, been unable to do more than glance at the questions raised by our correspondents. We have said enough, perhaps, to let them see that the locomotive has a private as well as a public life, and the private life is quite as much the locomotive superintendent's care as its public life. In a word, the engine has not only to draw trains, but it has to draw them with certainty and punctuality, and with the smallest possible outlay of money and time on repairs. Locomotives have their peculiarities—we had almost said their whims—and these have to be thought of. Any driver of experience who values punctuality will admit that good advice is contained in the words: If you have a sulky engine, take a pilot if you get the chance.

## PROGRESS WITH NAVAL CONTRACTS IN PRIVATE YARDS.

SATISFACTORY, not to say rapid, progress is being made throughout the kingdom with the British warships now under construction by private contract. On the Clyde, where there is a total of no less than 62,000 tons on hand—nearly two-thirds of the whole of the warship tonnage distributed amongst private firms—work, is to say the least, well advanced, although operations have been somewhat delayed by the recent coal strike. At the yard of Messrs. J. and G. Thomson, Clydebank, where Admiralty tonnage to the amount of over 30,000 tons is in hand, the position is one of satisfactory all-round progress. All the three torpedo-boat destroyers entrusted to the firm—the Rocket, the Shark, and the Surley—have been put into the water, the last of the three having been launched on the 10th inst. The Rocket has been handed over to the Government after having undergone preliminary trials during the last week of October. These proved in every way successful, the mean speed attained being 28·25 knots, equal to rather more than 32½ statute miles per hour and 1·25 knots over the contract speed of 27 knots. The Shark is being completed for her trials preliminary to acceptance by the Admiralty. No other firm in the kingdom, it may be stated, has launched three of the destroyers last given out, and none are now likely to outstrip the Clydebank firm in the matter of delivery. On the first-class battleship Jupiter and the first-class cruiser Terrible a fair amount of work has also been accomplished by Messrs. Thomson. Their former experience with the battleship Ramillies, built under the Naval Defence Act of 1889, is no doubt standing them in good stead with the Jupiter; but they are labouring, it is said, under the disadvantage common to all private builders, that the armour-plate contractors usually give a preference to the Royal Dockyards in the supply of material. In the engineering department at Clydebank not only is the work advancing on the machinery and boilers of 22,000-indicated horse power for the Jupiter, and on the engines for the Terrible, but the machinery for the warship Sultan is nearly completed, and will be ready for delivery at Portsmouth by the end of the year.

The Fairfield Company is pushing ahead with the three torpedo-boat destroyers it has on hand—the Handy, Hart, and Hunter—the first named being all but ready for launching. Progress is also being made with the two second-class cruisers, Venus and Diana, of the Talbot type. These, it may be stated, occupy the berths in which the great Cunarders were constructed. The two second-class cruisers under way in the yard of the London and Glasgow Shipbuilding Company, Govan, to be named the Dido and Isis, are progressing apace, and the same is true of the two torpedo-boat destroyers in the hands of the Abercorn Shipbuilding Company, of Paisley. The tonnage all this work represents—62,000 tons—exceeds any previous record as regards Admiralty work on the Clyde at any one time. If the Clyde builders, therefore, have had good reason to be gratified with the favour that was extended to their tenders in the spring, it seems, on the other hand, that the Admiralty have every cause to feel satisfied with the progress made with the Clyde contracts, and with the character of the work as well.

The proportion of Admiralty orders secured by the Naval Construction and Armaments Company, of Barrow, was relatively as noteworthy as the Clyde share, and at the present time the utmost energy is being displayed in the building of the first-class cruiser Powerful, the two second-class cruisers Juno and Doris, and the three torpedo-boat destroyers—Sturgeon, Starfish, and Skate—with all of which this company was entrusted. The order for the Powerful was received last New-Year's day, and the vessel is now well advanced in the plating stage, and a beginning has been made to sheath the hull to a height of about 3ft. above the water-line with teak, preparatory to covering it with copper. The two second-class cruisers are in frame to the protective deck, and the plating has been begun. The first of the three torpedo-boat destroyers, the Sturgeon, has been tried for speed, and the two remaining vessels are about ready for launching. In the engineering and boiler works department the Barrow Company is busy upon the engines for the Majestic, building at Pembroke, and they will be ready to despatch to that yard when the Majestic is launched at the close of the year.

At Messrs. Laird's, of Birkenhead, the Banshee, the first of the three torpedo-boat destroyers ordered at the same time as the others throughout the kingdom, was launched on the 17th inst., and work on the two remaining vessels is proceeding apace. The two recently handed over, the Ferret and Lynx, were part of an order placed prior to the giving out of the last general batch. Messrs. J. and G. Thomson, therefore, in having recently handed over the

Rocket, the first of their lot, and having just launched the Surley, the last of the lot, may be considered to have outstripped the Birkenhead firm in the matter of rapid construction and delivery. On the Mersey, as pointed out in a recent article in our columns, there is an almost complete lack of shipbuilding for the mercantile marine, so that there is little else to stand in the way of the Government work. Owing, doubtless, to this circumstance, Messrs. Laird have been able to make good headway with the first-class battleship Mars—a sister vessel to the Jupiter. A further circumstance connected with the work on this vessel is that she is being built in a dry dock; an immense advantage as regards the facility with which heavy masses can be put on and worked into the structure. The work in other private yards on the Tyne, Wear, Humber, and Thames, consisting chiefly of torpedo-boat destroyers, is, from all that can be gathered, progressing satisfactorily. The Ardent, the first of three destroyers built and building by Messrs. Thornycroft, was recently tried for speed, with the result that she attained 29·182 knots as the mean of two runs, one with and the other against the tide.

Work in the Royal Dockyards themselves is not allowed to languish. At Chatham two first-class battleships, the Magnificent and Victorious, and one second-class cruiser, the Minerva, are well under way; while, according to the terms of the Naval Estimates for 1894-95, an additional battleship of the Jupiter type, to be named Illustrious, will soon be commenced there. The Minerva will be ready for launching this year. For her engines and boilers, which are to be manufactured at Chatham, the naval authorities have allotted £90,770. The Magnificent has now got her barbettes fixed in position, a great portion of her protective deck complete, and she is ready for her armour-plates and engines. Portsmouth has three battleships and one second-class cruiser on hand. The first of these battleships, the Majestic, is advancing so rapidly that there is no longer a doubt that she will be floated before the end of the year, when some 6000 tons will have been built into her in a space of eight months. Pembroke is busy with two more battleships of the first class, the Renown and Hannibal, while Devonport has got on the stocks one second-class cruiser and two sloops.

The total tonnage under construction for the Admiralty is 220,210 tons; 123,640 tons of which are in the Royal yards, and 96,570 tons in private yards. The Royal establishments have probably about as much on hand as they can well overtake at one time; but with the private yards the situation is different. Last year, when the total output came to close on 900,000 tons, it was estimated that our shipbuilding facilities had only been utilised to the extent of two-thirds. This year's estimate promises to be very much to the same effect. When the Government decide, therefore, as they must do soon, to go on with another instalment of their programme, so as further to strengthen our navy, it is but natural that the private builders should expect to receive the same, if not, indeed, a greater proportion of the new contracts.

### UTILISATION OF THE NILE.

We have in the *Times* of Tuesday the text of the official notification of the proposed modification of the Assouan project, in the shape of a memorandum by Mr. Garstin. In it is recapitulated most of the information and arguments, already in the possession of our readers, as regards the other sites for dams on the Nile below Wadi Halfa. Beyond this he tells us that above Wadi Halfa, that is, south of it, Sir John Fowler's surveys, made in the reign of Khedive Ismail, for a railway projected to Khartoum, show that there is a possible site for a dam and reservoir at the Cataract of Hanneh, or at the Khaibar Gate. The Khaibar Gate is within forty miles of Dongola, and consequently no work would be possible there till the town is taken from the followers of the Mahdi. Another point is brought forward in the argument, which may be taken for what it is worth, and that is, that the emasculated Assouan dam scheme is only a step in a future scheme for the more complete utilisation of the Nile, which will fully serve the whole of the country, because that even if, as is possible, a reservoir be made in the future higher up the river, it will still be imperative to have a second reservoir nearer the point at which the water must be delivered for irrigation. The reason given for this being the waste which would inevitably ensue in the long shallow reaches and sandy side channels of the river on the way down. We confess that this argument and proposal looks like making the best of a bad bargain, and using an after thought as a thing to cover the retreat from the original Philæ proposal. We are glad, of course, to see that Philæ has been preserved for the archæologists, but at what cost remains to be seen. A heavy one, we fear, for it seems that an item in the estimates for the new dam at Assouan is to be an archæological and scientific investigation of the whole of Nubia. This may mean a big order, if the wishes of scientific societies are as stated, to be met in the matter, and it is scarcely fair to include it in the estimate of an irrigation project. We are told to expect this estimate in the spring of 1895; meanwhile it is stated that "the Public Works Department has been directed to put in hand as much of the archæological work as lies within its scope and power during the ensuing winter season. Topographical surveys will be made and plans prepared; the true bearings of the temples will be fixed and the preliminary plans of all sites completed. This portion of the work being done, the Egyptian Goverment will ask the European scientific societies to depute certain of their members to come to Egypt and complete the work."

### DYNAMOS AND COPPER PIPES AT SEA.

The last report of Mr. G. W. Melville, Engineer-in-Chief United States Navy, contains a very singular statement, which, if true, opens up a vista of extremely unpleasant possibilities to shipowners. It has once been said of electricity that "you never know where to have it, and in most cases it has you where you least expect it." Experience in the United States Navy seems to justify this expression of feeling if not of fact. Mr. Melville says: "The rapid destruction of copper piping in several vessels has already caused serious embarassment, and the reason for this deterioration has not yet been determined to an absolute certainty. As it always happens that a copper pipe conveying or surrounded by salt water, as the injection or delivery pipe to a pump, or the coil of a fresh water distiller, is the part attacked, and as the deterioration occurs only in steel ships fitted with dynamos, it is thought the injury may be caused by electrolytic action, since the copper of which the pipes are made is known to be of the very best quality, absolutely free from foreign matter, and therefore not affected by the corrosive action of salt water; in fact, precisely similar pipes, made of the same material, in iron vessels like the Alert or Ranger, which have no dynamos, last almost indefinitely. Steps are being taken to find out the true cause of this rapid destruction and the means by which it may be prevented." Mr. Melville is an extremely careful and competent man, and the more weight attaches to his words. Far-fetched as the theory may seem, we have no doubt that Mr. Melville holds that it has some foundation in fact, or he would not have promulgated it. It is unfortunate, however, that the issue is complicated by the circumstance that the Alert and Ranger are iron vessels. Now it is still a vexed question whether or not steel is more liable to corrosion than iron, and thus it may be said that the steel, and not the dynamo, is to blame. Why and how the dynamo should have anything to do with the matter it is by no means easy to see. As bearing on the same subject it may be worth while to mention that there is, it is said, good reason to believe that iron or steel yachts laid up close to vessels with coppered bottoms are very injuriously affected, the iron or steel corroding rapidly in spite of paint. It is by no means easy to see how the circuit can be completed in such a case, or to imagine that the current can be strong enough to do any mischief.

## LITERATURE.

*Railway Policy in India.* By Horace Bell, M. Inst. C.E., Consulting Engineer for State Railways to the Government of India. London: Rivington, Percival, and Co. 1894.

*Railways in India. Their Economical Construction and Working.* By E. George George, M. Inst. C.E., London: Effingham Wilson. 1894.

His official position gives Mr. Bell many exceptional advantages in dealing with his subject, and although he disclaims any official authority, yet as all his information is culled directly from sectariat records, his writing bears almost the stamp of a State document. Unfortunately, as a penalty for this advantage, his readers are deprived of the benefit of his personal views, and his mouth is closed to all criticism of the Government policy. However, he has produced a most interesting and useful narration of facts connected with the evolution and working of the Indian railway system. He divides his subject into seven chapters, of which the first and fourth have the greater general interest. The one discloses the history of the oscillations of the pendulum of official views on the question of guarantees and finance, the other recounts the story of the battle of the broad—Indian—and narrow—metre—gauges.

In tracing the evolution of the Indian railway system, we learn that as early as the year 1843-44 the first proposal for the construction of a line was advanced by Sir Macdonald Stephenson, and incredible as it may appear, it was at once received with favour by the Honourable Court of Directors, although at the time pressed by serious political anxieties, and sanction was given to the construction of an experimental railway between Calcutta and Allahabad in a despatch to the Government of India, dated May 1845. This and the Great Indian Peninsular were the first two railways started in the country; the gauge adopted was 5½ft., afterwards styled the "Indian or standard gauge." Thus commenced the movement which has given India railway communication extending from Cape Comorin to Afghanistan, and from the Indian Ocean to the Bay of Bengal, measuring 18,042 miles, and costing over £234,000,000 sterling.

From the year 1849, when Lord Dalhousie held the reins of Government, till the close of Lord Lawrence's term of office in 1869, the construction of Indian railways was on the broad, or standard gauge system, chiefly by the agency of guaranteed or assisted companies, and their extension, with the exception of the check caused by the mutiny made steady progress. But about this time the Government awoke to the economic disadvantages of the guarantee system, and constant attempts were made to arrive at a satisfactory settlement in the policy of guarantees and control; but no material change was made till at the close of his tenure of office Lord Lawrence bringing his intimate knowledge of the country to bear on the question, made out an unassailable case against the existing system; and his masterly review on leaving office led to the extension of the scheme for railways entirely and directly by State agency; and to the introduction of the metre gauge as a measure of economy by which the finances of India could be enabled to bear the burden of railway extensions so necessary for the safety and development of the resources of the country. This policy held for ten years, after which, up to date, the construction and management of railway lines have been about equally in the hands of the State and the Companies. At the same time, on most questions of finance, construction, gauge, working, and other matters, there seems to have been no settled railway policy with Government, or definite aim beyond that of protecting the interests of the country and the masses of its population.

Our author has in one of his appendices—C—exemplified the various changes of policy as well as of agencies that have been employed and arrangements that have been made, and gives much interesting and useful information in a tabular form including all the Indian lines.

We cannot in our space follow Mr. Bell into all the intricacies of the question of the gauges, which, as the world knows, was fought out bitterly for years both in England and India; statesmen, engineers, and soldiers ranging themselves on either side, and the policy that was fully and finally discussed in one decade was re-discussed, re-modelled, or even wholly altered in the next. This is the inevitable condition of things in India, with its frequently changing *personnel* of the Home and Indian Governments. Our author shows that as a whole these fluctuations of policy have been distinctly beneficial to the country; and he claims that the introduction of the metre gauge by Lord Mayo was a move in the right direction. Whatever may be the rights of the case, the upshot for the present has been a rational compromise, which even now must be considered as only provisional, for the developments of traffic throughout the country have been unexpected, and as yet no great military movement has afforded the experience which is necessary for the complete settlement of the question.

Our author's chapter on "Rates and Fares" will be read with interest and instruction by many on whose shoulders the cares of railway finance have descended. No better illustration of the paternal solicitude of the Indian Government for the mass of the population can be found than in their anxiety to bring down the railway rates and fares to the lowest paying level, and we see their endeavours from the earliest to keep down the tariff of the guaranteed lines, and when they became owners themselves they laid their measures to reduce and simplify rates and fares, and in the case of the lowest class, this reduction was carried to the extent of limiting the rate to 1½ pie—half a farthing—a mile, with the ultimate intention of reducing it still further, the managers of one of the State lines putting it that their passenger fares must be lowered "sufficiently to enable an ordinary coolie to travel more cheaply by rail than he can travel on foot." In India, as elsewhere, the third class affords the backbone of the coaching receipts; the other class might, as far as profit is concerned, be abolished; indeed, on most lines their removal would be a positive gain, and the author tells of a leading railway manager who stated it would pay him to give every first-class passenger twenty rupees to stay away.

The Government of India is in a position to show a good account for its stewardship, and the small volume under review helps to make this fact clearer; but their case is far from complete. Thousands and thousands of miles of railway still remain to be completed, and there is, as yet, only one mile for every 16,000 of population. A practical example is given us of the value of railway communication for military purposes, and a vivid illustration of the saving of time and money when, during the Afghan Campaign, there was a case in which one train, on a railway which had been rapidly pushed across the desert to the mouth of the Bolan Pass, was found to do in a day of sixteen hours the work which it would have required 2500 camels to do in a fortnight.

We learn from Mr. Bell that were it not for the serious loss by exchange, the Government of India might claim for their railway system unparalleled success as a national investment, for in 1892 the average return on all capital expenditure was 5·43 per cent. This is only the statistical result of the working, for, owing to exchange, the net loss to the State has been about 135½ lakhs of rupees. Had silver remained at par, a magnificient return would have accrued to the Government, for the loss on exchange alone in that year amounted to 153½ lakhs. The sterling interest charges now payable on Indian railways by Government in England are equivalent to a payment of interest at 7·6 per cent. on the total capital raised, if converted into rupees at par.

A clear little map, showing all the railways in India, in distinctive colours, accompanies the letter-press, and appendices, giving details of the standard dimensions to be observed on railways in India, and also a copy of the Indian Railway Act, with a table of contents and a good index, completes the volume.

In a little treatise of less than 100 pages of rather large type, Mr. George aims at compressing a large subject into a very small compass. His first chapter, in fact his whole work, bristles with statistical statement, and he gives his information with almost note-book brevity. Advocating the construction of railways for the political safety of India, he reproaches the British public with its supineness in overlooking such undertakings as a field for investment of capital, and he instances the case of 5136 miles of purely commercial lines constructed by joint stock companies, apparently without guarantee, earning 6·76 per cent. per annum per mile of railway. He makes out roughly a case for investors, and estimates in Chapter II. and Table VII. the cost of 300 miles of a 5½ft. gauge railway, the mode of construction, and working of which he describes farther on. He, however, deplores the unnecessary width of the Indian gauge, and believes that the English gauge of 4ft. 8½in. would have answered all purposes, stating that when the traffic had largely developed the metre guage had been unable to deal with it. His estimate per mile for the line he recommends is 1,08,701 rupees, and he takes the working expenses at 50 per cent. of the gross receipts, which he says, may be safely taken at 120 rupees per mile per week.

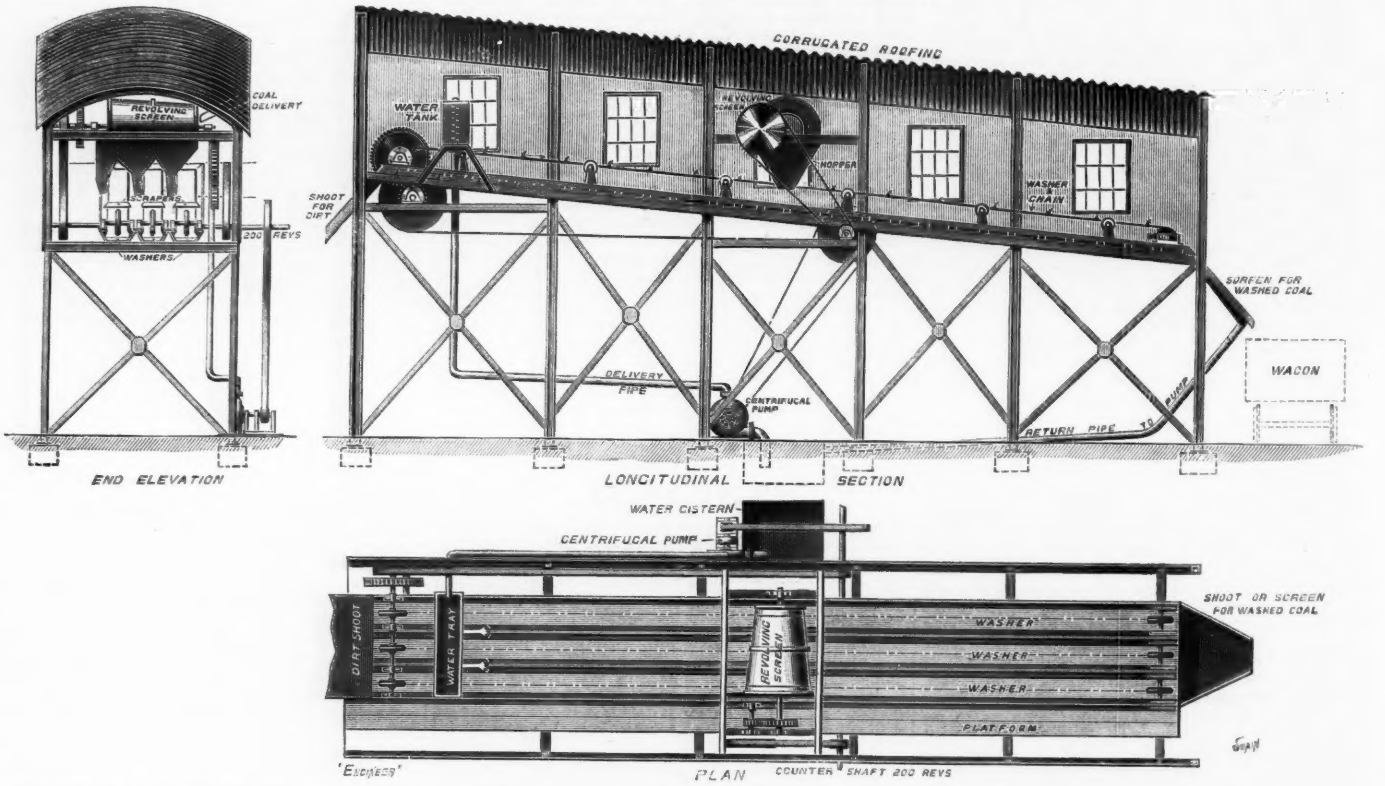
The author's advice on points of survey and construction is sketchy, but, as far as it goes it is good and practical. He is rather hard on the native character, and seems to have little sympathy with that valuable class, the native contractor. Yet at the same time he pronounces against the employment of the agency of large European contractors.

The author's experience seems to have been confined to the plains of India, and this is particularly noticeable in his observations on the founding in Viners and on the construction of earthworks and masonry in the fifth and ninth chapters. We chiefly note that the questions of terminal stations and telegraph communication have been left untouched. The value of the little treatise would have been enhanced by a good index.

**Portrait of Lord Armstrong.**—We have received an excellent reproduction of the latest portrait of Lord Armstrong. *Tyneside*, a new North-country monthly magazine, issues it as a supplement to its first and Christmas number. We congratulate our young contemporary both on the selection of a subject and the excellence of the workmanship. The portrait, we feel sure, will receive its due appreciation from all English engineers.

# ELLIOTT'S COAL WASHING PLANT

THE HARDY PATENT PICK COMPANY, SHEFFIELD, ENGINEERS



## ELLIOTT'S COAL WASHING PLANT.

In recent years, the fact that enormous quantities of small coal have to be disposed of at a very small or nominal price, on account of the large percentage of shale and dirt which is mixed with it, the coal itself being of good and useful quality either as a fuel or for the manufacture of coke, has directed attention to its careful washing and sorting. The usual and most efficient mode of separating the coal from the dirt is by washing. In the manufacture of coke it is essential that the coal should be as pure as possible, so that the ash may not exceed, say, 5 per cent. to 6 per cent. In addition to this, the shale or dirt having no coking qualities, but the reverse, it causes the coke to be unable to support much weight of iron in the furnace, instead of being strong and hard. After washing and grinding, the coke commands a ready sale. In the manufacture of briquettes, also, it is equally necessary to wash and grade the fine coal used or usable for the purpose.

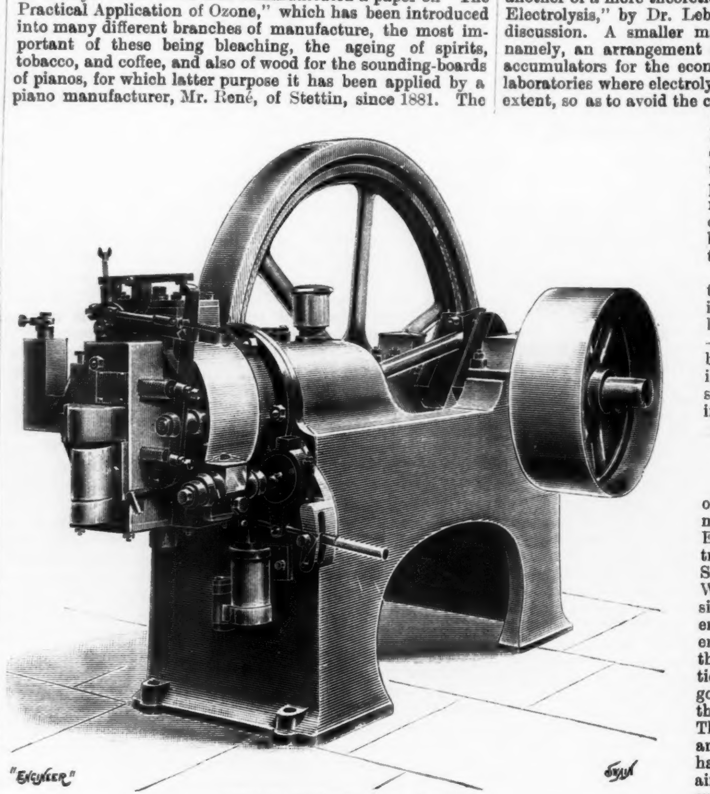
The plant we illustrate has been designed on the lines of the old trough washer. In addition to the difficulty, sometimes, of obtaining the necessary skill and attention, there was in the old troughs the necessity of changing the flow of coal and water into a second trough, while the dirt was being washed off and removed from the first when the stops had become charged with it; for if this was not done at the proper time some of the dirt became mixed with the coal, and the result was not satisfactory. The Elliott washer is automatic in its action.

The washer is constructed with a wrought iron or steel trough about 18in. wide, having sloping sides, being widest apart at the top and narrowest at the bottom. At each end of this trough a sprocket wheel is fixed, on which a chain rides, carrying scrapers. The scrapers form movable stops or dams which are slowly moved by the chain along the trough in the opposite direction to the run of the water. The coal is admitted at the centre of its length, and the water at its highest end or thereabouts, and as it runs to the lowest end it carries with it the coal, and the dirt settles in the scrapers and is conveyed by them against the stream of water and delivered at the opposite end to that at which the coal escapes. The speed of the scrapers and quantity of water is regulated to suit the material washed. As seen in the engraving, the coal is first delivered to a screen, thence the process is automatic.

## THE GERMAN ELECTRO-CHEMICAL SOCIETY.

A new society for the study of electro chemical problems, which was founded at a conference held in Cassel on April 21st, 1894, held its first general meeting at Berlin, on the 5th and 6th of October last, under unusually favourable conditions. Starting with 65 original founders, the number of members had increased to 271 at the time of the meeting, about two-thirds of the whole number being chemists, and the remaining part technical electricians. Among these, thirty members are from non-German countries, including three each from England and the United States. The object of the Society, as defined in the bye-laws, is the development of electro-chemistry in its scientific, technical, and economic aspects, and more particularly by the agency of meetings, a periodical journal, and correspondence with existing chemical and electrical societies. The first instance of the Society's activity, the Report of the First General Meeting, which has been forwarded to us by the council, is of an extremely interesting character, and contains several important communications. Among these we may specially mention a review of the work done by J. W. Ritter, a contemporary of Galvani and Volta, whose discoveries and writings between 1792 and 1808 entitle him, in the opinion of the author of the paper, Professor Ostwald, to be considered as the founder of electro chemistry. He certainly appears to have been the first to perceive that Volta's electro-chemical arrangement of the metals corresponded to the order of their affinity for oxygen. It is sad to think that an experimental philosopher of such high promise should in the later years of his short life have lapsed into mysticism and given himself up to pursuits not very dissimilar to those of the table-turner or spiritualist of later days. Dr. O. Frölich communicated a paper on "The Practical Application of Ozone," which has been introduced into many different branches of manufacture, the most important of these being bleaching, the ageing of spirits, tobacco, and coffee, and also of wood for the sounding-boards of pianos, for which latter purpose it has been applied by a piano manufacturer, Mr. René, of Stettin, since 1881. The wood is exposed to the action of ozonised air in a warm and closed chamber for a period varying from twelve to twenty-four hours, which has the same effect in producing uniform hardness and increased sonority as exposure to the air for several years. In this case the chemical change due to action of ozone on the resins contained in the wood is probably an important factor. The thickening of linseed oil which is effected in linoleum manufactories by allowing it to trickle over strips of gauze for several months, can in like manner be done with ozonised air in a few days. The conversion of crude potato starch into the soluble variety, as well as into dextrine and other gummy substances by ozone, has been effected by the author, and the method is to be introduced practically into a manufactory now in process of construction; but a more interesting application, which, however, is still in the experimental stage, namely, the production of nitric acid from the air, has also been developed by a method which will shortly be published; although, with the present low price of nitrate of soda, it is not likely to become commercially available in the immediate future. Specimens of nitrates made with nitric acid, produced by the direct oxidisation of atmospheric nitrogen, were exhibited at the meeting. The papers which seem to have excited the largest amount of interest were those by Dr. Borchers on "A New Galvanic Element," which we noticed in our issue last week, and another of a more theoretical character on "The Limits of Electrolysis," by Dr. Leblanc, which gave rise to a lively discussion. A smaller matter of some practical interest, namely, an arrangement of copper and zinc batteries and accumulators for the economic production of current in laboratories where electrolytic analysis is used only to a small extent, so as to avoid the cost and trouble of a dynamo, was brought forward by Dr. Heim, of Hanover, and a new form of incandescent lamp, in which alumnium terminals are substituted for platinum, by Dr. W. Bolton. The meeting was well attended, about one-third of the whole of the members being present, which is certainly a good beginning.

The second annual meeting is to be held in May or June, 1895, in some South German city, probably in one of the following three:—Munich, Frankfort, or Heidelberg. The member's contribution is fixed at 5s. entrance fee and 15s. subscription, payable on July 1st in each year.



WELLS' PREMIER OIL ENGINE

## WELLS' OIL ENGINE.

In The Engineer of the 13th of July last we described the manufacture of the Wells' Oil Engine, which ran through the trials of the Royal Agricultural Society at Cambridge in June last. We were not at the time in possession of a perspective view of the engine, but this we are now enabled to give above, which shows the design of the engine. The particulars of the vaporiser and governor were fully described in the impression above referred to. The engine is of the classes four and six of our classification, and has a vaporiser in which oil and air both pass through it as a charge enters the cylinder. The engraving we now publish shows the arrangement which we mentioned, but did not illustrate, which the makers have adopted for working the air-pump by hand, or by the engine when it has started. An excentric is mounted on the side shaft, which runs through the frame of the engine, and by means of a downwardly forked joint engages with the pump lever. As shown, the latter is pivotted by a pin in a slot, and the movement of the excentric operates the lever and the pump. When necessary to work the pump lever by hand, the pin shown towards the handle end is taken out, and the excentric fork joint becomes the pivot upon which the lever works.

Engineering Society, King's College, London.—A general meeting was held on November 23rd, the president in the chair. Mr. Herbert Jackson, F.C.S., read a paper on "Phosphorescence." The author defined phosphoresence and fluorescence, and then proceeded to exhibit the latter by passing a beam of limelight through a solution of fluorescence, the experiment being repeated with the light of sulphur burning in oxygen. An experiment was also shown to illustrate the damping effect of certain colour rays on the vibrations causing phosphorescence.

## RAILWAY MATTERS.

The Council of the Surveyors' Institution have nominated Mr. E. P. Squarey—past president—and Mr. C. Oakley—vice-president—to represent them at the Conference on Light Railways, to be held under the auspices of the Board of Trade on Thursday, the 6th of December.

The desirability of the provision of light railways has been emphatically affirmed by the Staffordshire Chamber of Agriculture. £1500—including land—was the attractively low estimate per mile mentioned by Mr. W. G. Bagnall, the Stafford manufacturer of locomotives and portable railways.

The following is a fair example of the way in which the hours-of-labour malady or craze has attacked some of our military-railway Board of Trade inspectors:—"The hours of duty of the guards of the train are not satisfactory. Donelly commenced work at 9 a.m. to sign off at 11.20 p.m., and though he was off duty for six or seven hours between whiles, the longest interval of rest was only two hours." Poor Donelly, only two hours rest with a few other odd hours during the day. Frightful to think of—a man working seven hours and twenty minutes in one day.

Notice has been given by the parliamentary agents of the London, Walthamstow, and Epping Forest Railway announcing their intention in the next session to ask authority to abandon the line, to release the deposit and to dissolve the company. It will be remembered that the promoters last session had a controversy with the London County Council on the question of workmen's fares, declaring that it would be impossible to raise the capital under the conditions sought to be imposed upon them, but the Bill was eventually passed on a compromise being arrived at between the promoters and the County Council.

Further work is in hand by the railway rolling stock firms. The Oldbury Railway Carriage and Wagon Company, Oldbury Works, near Birmingham, have taken a contract for ten bogie composite carriages for the Government of Western Australia. These carriages, which are to run on two 4-wheel bogies, are 42ft. 2in. long, and are intended for a 3ft. 6in. gauge. They are built on the English principle, with cross compartments for first and second-class passengers. The roofs are double with a clear air space between for ventilation. The outer roof is carried partly down the side of a carriage to form a sunshade, and by an ingenious arrangement is hinged and opens out with the door. The compartments are finished in sycamore, teak, and buffalo hide. The underframe and bogies are made of steel channels and plates, and all the carriages are fitted with the automatic vacuum brake.

In his report to the Board of Trade on the fatal accident which occurred on the 9th instant at a private road level crossing near Chatham station, on the Ashford and Canterbury line of the South-Eastern Railway, when as a one-horse wagon containing twenty-one hop-pickers and children, on the way from Canterbury to a hop garden, was crossing the line at the level crossing of a private road, it was run into, during a thick fog, by the engine of the 4.15 a.m. down goods train from Ashford for Canterbury, and the horse, the driver of the wagon, and six of those riding in it being killed, and nine others being more or less seriously injured, Major-General Hutchinson says the accident must be attributed to the imprudence of the driver of the wagon, which was conveying a party of twenty-one hop-pickers and others from Canterbury to the hop garden. It is almost unnecessary to say that the military-railway inspector craze about the number of working hours is also the burden of the conclusion of this report.

On the Mont Saléve Rock Railway, in Savoy, which is worked by electricity generated by water power, electric heating has been introduced into the carriages. The heating apparatus consists of two resistance boxes, 33in. wide by 12in. high and 7½in. broad, each containing forty-two coils of galvanised iron wire 1½ millimetres thick. These coils are 1in. in diameter, and contain about 20ft., or between 500 and 600 yards in each carriage. The current is taken directly from the rail conductor and passes through the coils, which are coupled in tension. The quantity absorbed is 15 ampères, which at 500 volts represents about 10-horse power. The temperature of the wire is raised to the boiling point of water, and that of the carriage is easily maintained at 60 to 70 deg. Fah., even in the coldest weather. In spite of the large amount of power required, this system of heating is possible on account of the traffic being small in cold weather, only four carriages being usually required, so that 30 or 40-horse power can be spared for the driving current for conversion into heat. The cost of the apparatus is £2 8s. per carriage.

The Lancashire, Derbyshire, and East-Coast Railway Company is applying to Parliament for powers to construct the Sheepbridge Branch and Clay Cross Branch Railways; to abandon certain railways, including the lines authorised under the Newark and Ollerton Act, 1887; and to empower the company to constitute a separate undertaking to take in hand so much of their railway as extends from Chesterfield to Lincoln, the Clown and Langwith Colliery Branches, the Markham and Bolsover Branch deviations, and the Sheepbridge and Clay Cross Branches. The new company will be known as the Lincoln and East-Coast Railway and Dock Company, which will have in hand the completion of the eastern section of the coast to coast railway. The Manchester, Sheffield, and Lincolnshire Railway seek for powers to construct lines in the parishes of Bestwood Park, Bulwell, Nottingham, Basford, Wilford, and Gotham, and for widening the company's railway from Retford to Gainsborough, and from Rampton to Torksey. Other railways are also contemplated in London and in different parts of the Manchester, Sheffield, and Lincolnshire system.

In reporting to the Board of Trade on the double collision which occurred on the 4th September, between Linlithgow and Philpstoun on the North British Railway—when owing to the severance of the train between the first and second wagons in the 12.10 a.m. up goods train from College (Glasgow) to Portobello, the rear portion of the train, consisting of thirty-four wagons and brake-van, was left standing on the up main line between Linlithgow and Philpstoun, at about 4.34 a.m., by the following train, the 12.45 a.m. up goods train from College (Glasgow) to Dundee, consisting of engine, tender, thirty-seven wagons, and brake van, Major Marindin says:—"Considering the nature of the double collision under investigation, it is providential that the results were not far more serious, for the escape of the guard of the 12.10 a.m. up goods train, the rear van of which was completely broken up, could hardly have been expected. The first cause of the collision was, no doubt, the severance of the train between the first and second wagons of the 12.10 a.m. train, and there is no evidence to show exactly where this took place. What may be taken as certain is that the wagon was properly coupled up before it started, and that the coupling was not broken, but in some manner became detached. This is a very unusual occurrence when a train is running on a nearly level line, with no changes of gradient to speak of, unless the train is checked very suddenly, when a coupling may be jerked off. It is easy to imagine that a driver leaving behind a few wagons out of a long train might, on a foggy night, not find it out; it is a different thing when, as in this case, he leaves the whole of a train of thirty-five vehicles, except one wagon, and the driver of the 12.10 a.m. train must be held to have been not sufficiently careful. He and his fireman had, at the time, been on duty for about five and a-half hours, the guard had been on for forty minutes less, and the signalman at Philpstoun for about ten and a-half hours." There is more, we need hardly say, about the working hours, which is the present craze of the Railway-military Department of the Board of Trade.

## NOTES AND MEMORANDA.

Phosphate of lime, obtained in the manufacture of gelatine, and known as precipitated phosphate and used as a manure, is admitted into France free from duty.

Electricity can be used to remedy blow-holes in defective castings by first drilling out the defects and then heating the castings, at the same time introducing scraps of steel, which are melted by the current, making a perfect joint without seam or flaw of any kind.

A high record for rail production was reached in October last by the Edgar Thomson Steel Works, at Braddock, Pa., the output amounting to 35,900 tons. In one twelve-hour turn 1800 tons were turned out, and on the other 1790 tons. The best previous record for production in any one month at this plant was about 33,000 tons.

Nitrate of ammonia can be used for freezing instead of ice and salt by mixing, if a small freezer be used, 7 lb. of nitrate with three quarts of water. The freezer is then rotated, and the cream or water is quickly frozen provided that the material is first cooled down before applying the nitrate. The nitrate can be recovered for further use by evaporating the solution to dryness.

Stage illumination by means of inverted arc lamps fixed so as to throw their beams on to a ceiling—the stage, &c., being illuminated by the reflected and diffused light therefrom, has been found a theoretical but not a practical success by M. Nerz. This is in consequence of a crater deposit, which disturbs the regularity of the arc. *L'Eclairage Electrique* says that the successful adoption of this method would involve the use of purer carbons than are made now-a-days.

Paper from sunflower stalks has recently been produced in the south of England; but as the fibre in the stems is too short to produce a material of fine texture suitable for writing or printing upon, the experiment is not likely to be continued. Some 500 lb. of sunflower stalk produced, by the aid of proper paper-making machinery, about 320 lb. of paper. This was not suitable for other purposes than packing, and to make a good paper it was estimated that the addition of 50 per cent. of rags or similar material would be necessary.

M. Forster, of the Berlin Observatory, has communicated to the *Revue Scientifique* the result of a series of observations carried on simultaneously for twenty months past at Kasan in Russia, Marburg in Germany, and Bethlehem in Pennsylvania, on "The Oscillation of the Axis of Rotation of the Earth." The object was to study the question of the supposed oscillation of the axis of rotation of the earth. From about 10,000 observations it appears that the pole or end of the axis has an oscillation following a spiral traced from west to east. The rate of oscillation is variable; at the present time it is decreasing. It appears, however, that the actual extent of this movement is very small, not exceeding 15 metres.

It appears from the columns of our contemporary, *Die Natur*, that a German chemist has made the discovery of a new compound body, which is said to possess the peculiar quality of solidifying under the action of heat, and to again revert to the liquid state at a temperature below 32 deg. Fah. To this substance the name of crostase has been given, and it is stated to be obtained by mixing equal parts of phenol, camphor, and saporine, with the addition of a smaller proportion of the essence of terebenthine. It is supposed that up to the present time no body possesses this remarkable property of liquefying when cold and solidifying when hot. It is true that certain substances such as albumen, for example, harden when exposed to heat; but once they have attained this condition, they cannot be made to resume the liquid state, although they may be subjected to exceedingly low temperatures.

At the last meeting of the Meteorological Society, Dr. H. B. Guppy read a paper on suggestions as to the methods of determining the influence of springs on the temperature of a river, as illustrated by the Thames and its tributaries. The methods suggested were:—(1) Comparison of the curves of the monthly means of the temperatures of the air and of the water for the river under observation with those of a river beyond the controlling influence of springs. (2) Comparison of the monthly means of the temperature of the river under investigation with that of a river beyond the control of the springs. (3) Comparison of the range of the monthly means of the river temperature with that of the air in the shade. (4) Comparison of the daily range of water temperature at different stations along a river's course. (5) Comparison of sunrise observations made at different stations along a river's course. (6) Comparison of observations made at different stations along a river's course at the hour of maximum temperature. (7) Comparison of the results obtained from a single series of observations made in one day along the whole course of a small tributary like the Wandle, or along the upper course of a larger tributary as the Kennet. (8) Determination of the distance from its sources at which the river begins to freeze.

At the last meeting of the Physical Society, Mr. Womack read a paper on "A Modification of the Ballistic Galvanometer Method of Determining the Electro-magnetic Capacity of a Condenser." The condenser is placed in parallel with one arm, S, of a Wheatstone's bridge arrangement of non-inductive resistances. A balance for steady currents having been obtained, the condenser is placed in circuit, and the throw on depressing the battery key determined. The condenser is then thrown out of circuit, and the proportionality of the arms of the bridge disturbed by changing the value of $S$ to $S + dS$. The steady deflection due to this change is then read. From these two readings and the known values of $S$ and $dS$ the capacity is immediately determined. In practice readings of deflection may be taken with equal positive and negative values of $dS$. To avoid changes of electro-motive force of the battery the author finds it best to use a reversing key in the battery circuit, and to observe the throw on reversing the current instead of on simply breaking it. One advantage of the method is that there is no need to know the galvanometer or battery resistance, and the author points out that it may be of service in the simultaneous determination of the resistance, and of the joint capacity and inductance of a submarine cable or of a telephone or telegraph line.

A simple method of obtaining light of different wave-lengths for use in polarimetric work is described by Landolt in the *Sitzungsberichte*, of the Berlin Academy, No. 38. White light from an Auer's glow-lamp is passed through different absorption cells containing coloured solutions which can be readily procured. Details are given of the preparation of five such cells, by means of which red, yellow, green, light blue, and dark blue light may be obtained. Examined spectroscopically, the light is in each case found to consist of a band, and is not by any means monochromatic; if, however, the rotation be less than 20 deg., or, with one or two of the cells, even if it be considerably greater, the field of the polarimeter remains apparently uniform in tint. The wave-lengths with which the bands may be taken to correspond were determined by using the cells in a set of observations on the rotation of quartz, and comparing the results with those obtained for the rotation of quartz by Broch's method. The wave-lengths were thus ascertained to be not far removed from those of the Fraunhofer lines, C, D, E, F, G. The instrument employed was a Laurent half-shadow polarimeter fitted with a Lippich polariser. A simple method of this kind has, *Nature* says, long been required for the speedy investigation of rotary dispersion. It is also of importance to have a ready means of obtaining light of short wave-length, which if of especial service when determining the rotary power of feebly active substances.

## MISCELLANEA.

It is reported that a landslip has blocked up the Corinth Canal.

At a recent committee meeting of Navy and Dockyard officers at Devonport, it was decided to commence at once laying the foundation for a defence boom as a means of protection for Plymouth, constructed similarly to that recently provided at Chatham for the defence of the Medway.

In the coming session of Parliament application will be made by the Charing-cross and Strand Electricity Supply Corporation for authority to undertake the lighting of the Strand district by electricity; and the County of London and Brush Provincial Company will also seek power to light the districts of St. Mary, Newington, St. Olave, and Battersea.

The official reports continue to show that the rate of increase of the population of London as measured by births is decreasing. In London 2494 births and 1275 deaths were registered last week. Allowing for increase of population, the births were 199 and the deaths 416 below the average numbers in the corresponding weeks of the last ten years.

Experiments were made last week at Cureghem, a suburb of Brussels, with a new rifle, the invention of M. Marga, an officer in the Belgian army. The main feature in the invention is the cartridge, which is so arranged as to contain what are practically two charges. These are fired in succession. The extraordinary muzzle velocity of 3000 foot-seconds was attained. The sole objection to the new weapon seems to lie in the increased cost of and labour of filling the cartridges.

The Secretary of the United States Navy has asked Congress to order three new battleships, each of 10,000 tons, and twelve torpedo boats. This will involve an additional expenditure of £2,800,000. The estimates for the coming year demand £3,560,000 for the ordinary expenses of the navy, and £2,652,080 for the proposed increase, including armament. In addition the Secretary of the Navy recommends that in future no premiums for speeds shall be given to builders.

The Portuguese Government have entered into a contract with Messrs. Yarrow and Co., of Poplar, for the immediate construction of two shallow-draught stern-wheel gunboats, to take part in the Portuguese operations at Lorenzo Marquez. According to the *Times*, the vessels are to be 89ft. in length by 18ft. beam, and will have a draught of 18in. and a speed of ten miles an hour. They will be somewhat similar to the Mosquito and Herald, built by the same firm for the British Government for service on the Zambesi.

On Wednesday the Commission appointed by the Board of Trade under the Thames Conservancy Act, 1894, to inquire as to the improvement of the Thames between Thorney Creek and the Nore Lightship held its first meeting at the offices of the Thames Conservancy. Mr. J. Wolfe Barry, C.B., who presided, said that meeting was a preliminary one for the discussion of future proceedings, and the one desire of the Commissioners was to give everyone concerned the fullest opportunity for offering information. A discussion followed as to the course to be pursued in the inquiry, and the Commission then adjourned till the 18th of December.

The *Weekly Weather Report* of the 17th instant shows that in many districts the rainfall greatly exceeded the mean; over all the southern counties of England the amount was nearly four times as much as the average. The largest amounts recorded at individual stations during the week were 6·25in. at Godmanstone—near Dorchester, 5·51in. at Scilly, 5·13in. at Killarney, and 4·70in. at Falmouth, while 4·60in. fell at Crowborough, Sussex, in six days. The rainfall since the beginning of the year has now exceeded the average in all districts, except the Midland Counties and the West Coast of Scotland. The excess in the South of England and South of Ireland amounts to over 5in.

According to some statistics issued by the German Ironmasters' Association, the total production of pig iron in the Fatherland during September of the present year was 473,000 tons, which exceeds by 62,877 tons the figure for September, 1893. The production of the first nine months of 1894 was 4,088,246 tons, against 3,646,873 tons for the corresponding period of last year, showing an increase of 441,373 tons. The quantity produced during the first eight months of the present year, viz., 3,236,680 tons, is composed of forged pig and spiegeleisen, 1,035,035 tons; Bessemer pig, 222,468 tons; basic pig, 1,473,291 tons; and foundry pig, including castings produced directly from the blast furnace, 599,893 tons.

Experiments as to the visibility and audibility of torpedo boats at night have been made off Newport by the United States torpedo boat Cushing, which had been previously painted with a suitable colour. In the first experiment the Cushing steamed out from shore at night, having a powerful search light from the land directed upon her. At a distance of a thousand yards she became invisible from the shore, although it was light enough on the Cushing herself to read. The second experiment was to determine the distance at which the boat could be detected by her noise. The report says:—"Eight hundred yards is the maximum torpedo range, and a speedy craft would make great progress inside of this before guns could be trained upon her; so it is still questionable whether the search light is much of a safeguard against an attack from torpedo boats."

The Government of Brazil, through its special representative in France, Admiral J. de Proenca, has arranged with the Société des Forges et Chantiers de la Méditerranés at La Seyne, near Toulon, to build for it two ironclad battleships 267ft. 6in. long, 46ft. 11in. broad, and displacing, at a draught of 13ft. 2in., 3162 tons. *The Times* says the designs are by M. Lagane, director of the yard at La Seyne. With natural draught the engines will develope 2650-horse power, and give a speed of 13 knots; with forced draught, they will develope 3400-horse power, and give a speed of 14 knots. Each will have two turrets, and its armament will consist of four 9·4in. breech-loading, four 4·7in. quick-firing, two 5·9in. rifled howitzers or long mortars, two 3in.—12-pounder—quick-firing, four 2·24 in.—6-pounder—quick-firing, two 1·45in.—1-pounder—quick-firing, and two 1in. machine guns, with torpedo ejectors. There will be a thick steel belt, a steel protective deck, and heavy armour on the turrets.

Following a similar action taken by the Dover Harbour Board on Tuesday, the Dover Corporation on Wednesday evening decided unanimously to memorialise the Government to allow convict labour to be employed in escaping and rendering safe the dangerous area of cliff near the convict prison which, it is proposed, shall be closed, although it has cost £108,000 to erect. In drawing attention to the advantage the work would be to the Government as well as to the town, the memorial points out that, if undertaken, it would promote the employment of non-convict labour for several years to the extent of 700 or 800 men, who would be engaged in utilising the *débris* thrown down by the convicts from the cliffs to form a roadway and seawall at the base, where a roadway existed as far as St. Margaret's Bay until it was gradually and completely washed away by the sea. During recent years the encroachment of the sea here has been most serious, and enormous falls of cliff take place very frequently. In reclaiming and protecting the foreshore as proposed, all further erosion of the cliffs would, the memorial declares, be effectually prevented, and the lighthouse and other Government buildings within the area would be rendered safe from a danger which must ultimately threaten their security.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Garbage disposal.*—A commission from New York city is now visiting the various cities in which garbage cremators or other disposal plants are in operation. The Dixon system, at Atlanta, Pa., consists of two reverberatory furnaces, one on top of the other. The flame comes from coal burned in the fire-box. The garbage is dumped into the upper furnace, and, as soon as it dries, it falls through grate bars to the lower one. The fumes, gases, and odours evolved are carried to another furnace under the stack, where an auxiliary fire of coke consumes them. There is said to be no odour, although in the forty tons of stuff burned during twelve hours there are 120 barrels of night-soil, and this carries at least 60 per cent. of water. A dead horse put into the upper chamber had vanished, bones and all, in one hour and ten minutes. The furnaces consume four tons of coal a day. The process is rapid, complete, and perfectly odourless, and the smoke from the stack is slight and has no smell, except that of burning coal. At St. Louis, Mo., the St. Louis Sanitary Company has a ten years' contract for garbage disposal, and operates the Metz system. The wet garbage is placed in receivers, where it drains. It is then put into steam jacketed dryers, where it is constantly stirred for three hours. Transferred to retorts, it is saturated with naphtha, which dissolves all the grease, and this is then distilled off. The residue is ground up fine, placed in packs and sold for fertilising purposes, bringing 8 dols. a ton. The grease, which is odourless, is sold also for 8 dols. a ton to a firm of soap makers. Like all utilisation processes, this has a vile smell, which is complained of by people living five blocks from the works. The people in Detroit protested so strongly against it that the works were moved out of the city. The St. Louis plant is well out of the city limits. The city pays the company 1·80 dols.—or 7s. 6d.—a ton up to 100 tons, and all over that is treated for nothing. The average amount is 180 tons a day. One of the best and most satisfactory systems of cremation is that of the Eagle Company, in which two fires are used, the products of combustion from the garbage passing over the second fire and through a long firebrick chamber, in which these products are completely consumed. This system was employed, with entire success as to efficiency and freedom from odour, at the Chicago Exposition, oil being freely used.

*A bridge of* 4300*ft. span.*—In a recent number of THE ENGINEER was printed a report from a board of prominent bridge engineers in America, showing that a suspension bridge of 3100ft. span is entirely practicable, and is preferable to a cantilever bridge for the crossing of the Hudson river at New York. A report from another board of engineers, also made to the Government, shows that even 4335ft. is possible. This report adopts a steel cable of 6000 wires as the basis of construction for a six track bridge. The strength of such cables is 28,440 tons, giving a working strength of 9480 tons. The diameter would be 21½in., as against 15⅝in. for the Brooklyn bridge. The towers would be 707ft. above the masonry, and weigh 57,172 tons. The total weight of metal in the bridge would be 233,899 tons. After giving in great detail the calculations for this great structure, the board turns its attention to the Hudson river bridge project. It takes up the report of the bridge commission, which fixed the cost of the bridge at 30,743,000 dols., and pointing out that this was a maximum estimate, and that the board expressly stated that it was not to be taken as an absolute estimate, the engineers submit a new estimate considerably reducing the figures. The minimum estimate is given as follows: —Weight of structural steel, 161,507,000 lb. at 4 cents per lb., 6,460,280 dols.; wire work, weight 56,318,000 lb., at 7 cents per lb., 3,942,260 dols.; cost of superstructure, 10,402,540 dols.; of substructure, 11,784,000 dols.; total cost of bridge, 22,186,540 dols. Summing up, the board finds that 23,000,000 dols. is a reasonable estimate for a six track suspension bridge 3200ft. long, and they consider the amount of traffic which such a bridge would accommodate sufficient to warrant the expense of construction. They believe, however, that the bridge should be so constructed that its capacity can be readily increased, and with the suspension system this can be provided for by giving suitable dimensions to the towers and anchorages. The board suggests that competitive designs be invited for such a bridge.

*Fireproof floor construction.*—A very general method of floor construction for office buildings, factories, &c., consist of hollow firebrick blocks laid together between the I-beams or rolled joists of the floor framing, forming a flat arch. The end blocks fit the shape of the floor beams, and the others are of rhomboidal section, except the middle one, which is slightly wedged shaped, forming the keystone. The blocks are supported during construction of the floor by a platform of planks under the floor beams. They are laid in cement; the bottom is roughened so that the ceiling is attached directly to the blocks, and a thin concrete or cement floor is spread over them. The blocks are very light in weight, but very strong, being hollow, with intersecting ribs, and such floors can carry very heavy loads. In the latest form of such floors, the end blocks, or skewbacks, are the full depth of the beams, but the others are shallower and have curved top surfaces, so that the finished arch has actually an arched-shaped top surface, arched ribs in the hollow blocks, and a flat surface for the ceiling. The floor is filled in level with ashes or cement. This arrangement really acts as an arch, while the ordinary flat arch acts merely as a beam. A somewhat different construction is the use of concrete arches, the concrete being filled in an arched centreing and resting on the lower flanges of the beams. Where the spans are considerable, arches of light angle, tee, or H-irons, are placed between the floor beams, about 4ft. apart, and concrete is filled in between them, forming arches whose ends rest upon the floor beam flanges, and whose sides rest upon the arched irons.

## LAUNCHES AND TRIAL TRIPS.

The steam vessel Scotia, which has just been constructed by Mr. James Weatherhead, Eyemouth, for Mr. Richard Irvin, North Shields, went on trial on the Forth on the 22nd inst., and attained a speed of 10 knots. Her engines, which are compound surface-condensing of 200-horse power, have been supplied by Messrs. John Cran and Co., engineers, Leith.

Last week Messrs. Ropner and Son completed and despatched from their Iron Shipbuilding Yard at Stockton-on-Tees the following steamers for their trial trip, viz., the s.s. Harald, the s.s. Glanton, and the s.s. Dovedale. On the 28th instant Messrs. Ropner and Son launched a very finely-modelled steel steamer of the following dimensions, viz.: Length between perpendiculars, 300ft.; breadth, 42s. 6in.; depth moulded to awning, 32ft. 6in. She will have triple-expansion engines by Messrs. Blair and Co., of 1000 indicated horse-power, with two large steel boilers 160 lb. pressure. The steamer has been built to the order of a Newcastle firm, and was named Carlton by Mrs. Pellew.

The s.s. Bainbridge is a fine steel screw steamer, built by Messrs. William Gray and Co. to the order of Messrs. Crosby, Magee, and Co., of West Hartlepool. She has been built to Lloyd's highest class, and is of the following dimensions, viz.:—Length over all, 280ft.; breadth, 27ft.; depth, 19ft. 6in. The engines have been supplied by the Central Marine Engine Works of William Gray and Co., and are of the triple expansion type, working on three cranks. The cylinders are 19in. by 30½in. by 51in. in diameter, and the stroke is 36in. The boilers are of large size, working at 160 lb. per square inch. On her trial trip the engines were driven at 60 revolutions per minute, a speed of over eleven knots being attained without any hitch or trouble with the machinery in any way.

On Tuesday there was launched from the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, a very fine steel screw steamer which has been built to the order of Messrs. Lamport and Holt, of Liverpool, for the Liverpool Brazil, and River Plate Steam Navigation Company. This vessel has been specially designed to suit the South American trade, and is exceedingly well fitted in every department. The principal dimensions are: Length, 321ft.; beam, 42ft.; depth moulded, 25ft. 6in.; and she takes Lloyd's highest class, as well as Board of Trade certificate. The machinery will be fitted by the North-Eastern Marine Engineering Company, of Wallsend-on-Tyne, the cylinders being 24in. by 40in. by 64in. by 42in. stroke, with two large double-ended boilers working at 180 lb. pressure. As the vessel was leaving the ways she was named the Homer by Mr. Watt, of Eaglescliffe.

On Wednesday last the new Norwegian steamer Solveig, built by Messrs. C. S. Swan and Hunter, of Wallsend, to the order of Messrs. Christian Michelsen and Co., of Bergen, was taken to sea for her trial trip. Her principal dimensions are: 340ft. length by 44ft. beam by 29ft. 10in. depth to spar deck; to class 100 A1 at Lloyd's, and is the largest steamer by nearly 1000 tons now owned in Norway. The steamer will carry a deadweight cargo of 5500 tons, and a measurement cargo of about 6500 tons on a moderate draught. She is supplied with a full equipment of powerful steam winches and very complete cargo gear. The machinery has been constructed by the North-Eastern Marine Engineering Company, Wallsend, the cylinders 24in., 40in., and 64in. diameter, by 42in. stroke, supplied with steam at 160 lb. pressure by two exceptionally large boilers, which on the trial trip maintained more steam than was required. Whilst the machinery was working at sixty-seven to sixty-eight revolutions a speed of 11¾ knots was attained during the run along the coast, a speed which can only be considered as highly satisfactory both to the owners and the engineers. The shipbuilders were represented on the trial by Mr. Rowland Hodge, and the engineers by Mr. Summers Hunter, whilst the owners' agents in Newcastle, Messrs. Dent and Co., were also on board. During the construction of the vessel she has been superintended by Captain Rodseth, on behalf of the owners, and on the conclusion of the trial trip, which was in every way satisfactory, Captain Rodseth expressed his entire approval of both the vessel and machinery, and afterwards immediately shaped a course for Philadelphia, where the Solveig will take on board 140,000 cases of oil for Japan.

On Tuesday the fine new steel screw steamer Musician, built by Messrs. C. S. Swan and Hunter, to the order of Messrs. T. and J. Harrison, of Liverpool, was tried off the Whitley measured mile. She has been built for their East India and general trade, is 400ft. between perpendiculars long, by 47ft. broad, by 31ft. 6in. depth moulded, and is built on the three-deck grade, of the highest class at Lloyd's, and under their special survey. She has a full poop, with long bridge deck and topgallant forecastle. The cellular double bottom extends the length of the vessel. The winches and derricks are of unusual size and number to suit the owners' particular requirements, and the whole of the cargo gear is of the most complete description, and made especially to Captain Gell's design. The engines are by the Wallsend Slipway and Engineering Co., Wallsend, having cylinders 27in., 44in., and 71in., by 42in. stroke; the boilers are built for a working pressure of 180 lb. on the square inch. After a satisfactory trial a speed of 13·48 knots was obtained, the engines running at 72½ revolutions per minute, and to the satisfaction, in all respects, to the owners' representatives. The steering of this large vessel was particularly marked, the half-circle being performed in three minutes, and she was stopped dead in one and a-half minutes after the order was given to go full speed astern, just as she completed the measured mile, and when running at full speed. The vessel proceeded on her voyage to New Orleans. The construction of the vessel and machinery has been superintended by Mr. C. W. Cadman, Captain W. Gell, and Mr. W. Sargeant, who also represented the owners on the trial trip. The builders were represented by Mr. E. W. De Russett, and the engine builders by Mr. L. Rusden. The vessel is the second of the same dimensions which these builders have constructed for Messrs. T. and J. Harrison.

On Wednesday, November 21st, the s.s. Strathfillam went on her trial trip from Hartlepool. The vessel is a sister ship to the Strathness, Strathnairn, and Strathord, and is the fourth steamer built by Messrs. William Gray and Co., Limited, to the order of Messrs. Burrell and Sons, of Glasgow. She carries 6400 tons dead weight, and is 376ft. 6in. in length, with a breadth of 47ft. and depth of 39ft. 9in. Her engines are supplied by the Central Marine Engine Works, and are of the triple expansion type, having cylinders 27in., 43in. and 72in. in diameter respectively, with a piston stroke of 45in. Steam is supplied by two large single-ended boilers working on the forced draught system, patented by Mr. Howden, of Glasgow, the steam pressure being 170 lb. per square inch. The air fan is in the engine-room, and is driven by a separate vertical engine. The machinery throughout is precisely similar to that supplied to the sister ships previously mentioned, except in respect to the engine-room telegraph, and in this case, as in that of the Strathord, this piece of mechanism is an improved device manufactured by Messrs. Mechan and Sons, of Cranstonhill, Glasgow. This telegraph is combined with the engine, and placed upon it on the centre front column, instead of being a totally independent instrument placed on the bunker or bulkhead. It is called the "Triple Automatic" Engine-room Telegraph, and it derives its name from the fact that it contains three pointers instead of the usual two, the third one being actuated by the reversing gear of the main engines. The action is as follows:—When the order is given from the bridge for the engines to be driven ahead, the bell rings and the pointer points towards the bow of the ship. The engineer then replies by means of a handle or lever which works thwartships in the same manner as an engine starting handle, and this movement brings the second pointer over the first, so that two pointers now point towards the bow of the ship. The engineer then applies steam to his reversing gear, and as this moves to give steam to the engines for going ahead, it also moves the third pointer of the telegraph, so that that also comes to lie over the other two, and thus finally all the three pointers are pointing toward the bow of the ship. One of the main objects of this arrangement is that the engineer can no longer by any possible lapse of attention deceive himself as to which way he is driving the engines.

THE ROYAL MAIL STEAMER NORMAN.—The Union Steamship Company's twin-screw Royal Mail steamer Norman, which left Southampton on the 10th November with the Cape of Good Hope and Natal mails, arrived at the Cape *viâ* Madeira at 5.10 p.m. on the 26th. Passage 15 days 19 hours net steaming time, and average speed 15 9 knots per hour.

THE INSTITUTION OF CIVIL ENGINEERS: NEWCASTLE-UPON-TYNE ASSOCIATION OF STUDENTS.—The second meeting of the present session was held in the Durham College of Science, Newcastle-on-Tyne, on Wednesday, the 21st inst., the President, Mr. C. A. Harrison, in the chair, when Mr. W. O. E. Meade, M. Inst. C.E., read a paper on the "Irlam Section of the Manchester Ship Canal." The paper began by giving the position of the Irlam section of the Ship Canal, which is not more than five miles long, but where, owing to the number of times the canal crosses the courses of the rivers Mersey and Irwell, the excavation was rendered especially difficult. The strata and methods of excavation were next noticed, the latter being carried out by Ruston and Proctor's steam navvy, Wilson's excavators, and the French and German land dredgers, according to the nature of the ground to be dealt with. After giving the section of the canal, which is 120ft. wide at the bottom, with 26ft. of water, and describing the different methods of protecting the sides by pitching and fascine work, the author went on to describe in detail the locks and sluices at Irlam, and the methods adopted in their construction. The paper concluded with an account of a flood which took place in November, 1890, and by which some three-quarters of a mile of the Irlam section was filled with water, all of which, together with the material brought in by the water, had to be pumped out and excavated again.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE chief event this week is the issuing of the accountants' certificate to the Iron Trade Wages Board of the realised prices of manufactured iron for September and October last. The figure returned is £5 16s. 5d. per ton, against £5 18s. 5d. for last July and August, and £6 3s. this time last year. Thus there is a reduction of 2s. on the bi-monthly period, and 7s. on twelve months back. It has been resolved to reduce all ironworkers' wages by 2½ per cent., making the remuneration of puddlers 7s. 3d. per ton. This is the first reduction in wages that has been made since the end of January last. At that time a drop of equal amount to that now declared took place, and wages, which had previously stood at 7s. 9d. for puddling, came down to 7s. 6d. This change was the result of the accountants having reported a falling-off in the selling prices of iron of 1s. 8d. per ton. Since that date there has been a further fall of altogether 4s. 10d., but the only wages change has been that declared this week.

Concerning the affairs of the Earl of Dudley's Round Oak Ironworks Company, Brierley Hill, to which I referred three weeks ago, it has this week been resolved by the shareholders to wind up under voluntary liquidation, and arrangements will be made under which the works will shortly revert back to their original owner, Lord Dudley, as sole proprietor. The company was formed in 1890, and his lordship holds mortgages and debentures amounting to £100,000. The unsecured creditors are set down at about £10,000, but it is hardly expected that these will receive anything unless Earl Dudley voluntarily concedes a dividend.

Negotiations for the formation of an All-England Association in the Galvanised Iron Trade continue, but the chances of success do not appear to be very rosy. About ten or eleven firms have definitely replied, accepting the association and also the rules as at present drawn up. An equal number have sent replies favourable to the scheme, but suggesting alterations upon various points; and some eight firms have either withheld their approval or have not replied at all. Thus the complete number of twenty-eight or twenty-nine firms engaged in the trade throughout England and Scotland is accounted for. The non-adherents, if their opposition is persisted in, are strong enough numerically to spoil the scheme. With a view to prevent this, a select sub-committee of the organising body has within the past few days been appointed to further negotiate. The sub-committee will seek interviews with the eight non-subscribing producers, solicit their reasons for standing aloof, and if possible induce them to abandon their position of indifference. A further meeting of the organising committee will be held when these firms have been seen.

The Indian order in hand by the Oldbury Company, briefly alluded to a fortnight ago is an extensive one. It is for the Bengal and North Western Railway—metre gauge—and includes 10 composites, 10 intermediate class, 90 third-class, 20 brake vans, and five horse boxes. The order includes the channel steel underframes and ironwork, body steel and ironwork, galvanised roofing, lavatory fittings, metallic fittings, trimmings, glass, &c. The brake vans and horse boxes are four-wheeled, and the composites, intermediates, and third-class are six-wheeled. The composite has entrances from the side and end, and is provided with upper and lower berths, and full lavatory accommodation. The intermediate class is of the English saloon type. The third-class has six compartments, with cross seats. All the carriages have corrugated galvanised roofs, sheet steel panels, and the usual sunshades for the Indian climate. The brake vans and horse boxes are of the customary Indian States type.

The Dudley Chamber of Commerce have forwarded to the Board of Trade the following resolution:—"That it is advisable that the Board of Trade take steps to amend the Chain, Chain-Cables, and Anchor Act, so as to include the proper testing of all rigging, crane, and hoisting-chain for use in British ships or within the United Kingdom; also that the practice which now exists of using false certificates of test, should be dealt with in a stringent manner." Sir B. Hingley, M.P., the chairman of the Staffordshire Iron Trade, is one of the promoters of this reform.

Industrial hygiene is making headway. This week a first meeting has been held in Birmingham of the special committee just appointed by the Home Secretary to conduct a Government inquiry into the condition of all branches of brass manufacture, and also the casting and mixing of gun-metal, bell-metal and kindred amalgamations. Their main duty is to recommend what, if any, special rules should be made under the Factory and Workshops Act, for the protection of the workpeople. The manager to Messrs. Winfield of Birmingham, is one of the members of the committee.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—A despondent tone continues throughout the engineering and iron trades of this district, so far at least as any prospect of improvement in the immediate future is concerned. In the iron market business just drags on at low and unremunerative prices, with very few transactions of any weight put through, and both makers and manufacturers are in most cases short of orders, with the result that there is a tendency to give way upon quoted rates rather than allow business to pass. The steel trade also remains in a depressed condition, and for both raw and manufactured material very low prices are being quoted. The coal trade, judging from the general complaints made by colliery representatives, could scarcely be in a much worse position, and for the season of the year, with pits barely working four days per week, stocks are accumulating, and the tendency of prices is rather in a downward direction than otherwise.

There was about a full average attendance on Tuesday's Manchester Iron Exchange, but both makers and merchants, with few exceptions, reported a continued absence of business of any real moment coming forward, and there was again a more or less general want of firmness in prices, with a good deal of underquoting to get hold of business, and very low sellers here and there for forward delivery. Users of pig iron still go on buying merely from hand to mouth, and where they do enter into anything like forward transactions of any weight, exceptional prices have to be quoted as an inducement. As an illustration of the business of this character which is occasionally put through, I may mention that in Scotch iron a considerable sale for forward delivery has been made during the past week to one of the large users in the district, at prices which are reported to be quite 2s. per ton under current quotations.

Lancashire makers still quote on the basis of about 39s. for forge up to 42s. for foundry, less 2½ per cent., at the works, but they are booking no business of any moment at these figures, and the orders they do secure are chiefly with special customers, where they have exceptionally favourable rates of carriage, as they are altogether out of competition with the much lower priced district brands in this immediate market. Even Lincolnshire and Derbyshire makers, notwithstanding their much lower prices, also report trade as excessively quiet. The full average quoted rates are now about 38s. for forge to 39s. for foundry Lincolnshire, with about 43s. up to 45s. for Derbyshire foundry, net cash delivered Manchester, but these figures are difficult to obtain, and in some cases there are sellers at lower prices. Outside brands offering in this market are rather easier, if anything, good foundry Middlesbrough not averaging more than 43s. 10d. up to 44s. 4d., net cash, delivered equal to Manchester; whilst in Scotch iron, although sellers are asking about 46s. 9d. for Eglinton, for prompt delivery, at the ports, they would in some cases take considerably under this, for forward sales, and for Glengarnock makers are nominally asking about 48s., with merchants offering 47s. net, prompt cash, delivered at the ports, and something between these figures would probably represent the basis on which business might be done.

Manufactured iron makers still report only a very limited weight of orders coming forward, with forges but partially kept going; and although quoted rates are unchanged actual selling prices here and there are rather easier. For inland sales, however, Lancashire bars could scarcely be quoted under £5 6s. 3d. to £5 7s. 6d., delivered Manchester, although £5 5s. has been taken on shipping orders. Staffordshire bars are quoted £5 7s. 6d. to £5 10s. Lancashire and Staffordshire sheets now range from £6 17s. 6d. to £7 2s. 6d., while Lancashire hoops are quoted £5 17s. 6d. for random and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Business still comes forward but very slowly in the steel trade, and prices continue low. Ordinary foundry hematites do not average more than 52s. 6d., less 2½; low-class billets, £3 17s. 6d. to £4, and better-class billets quoted £4 7s. 6d. to £4 10s.; ordinary steel bars, £6 to £6 2s. 6d., and boiler-plates, £6 2s. 6d. to £6 5s., delivered in this district.

In the metal market the reduction in prices which has been expected for a week or two back has at length been conceded, but only to the extent of ¼d. per pound upon all descriptions of manufactured goods, and this has brought forward no increased weight of buying. List quotations for delivery, Manchester district, may now be given:—Solid drawn brass boiler tubes, 5¾d.; brass surface condenser tubes, 7¼d.; copper tubes, 7½d.; brazed copper gas and steam tube, 7d.; brazed brass gas tube, 6¼d.; brass wire, 5d.; copper wire, 6d.; rolled brass, 5d.; sheet brass, 6d.; yellow metal condenser plates, 4¾d.; yellow metal bolts, 5½d. per pound, and copper bolts, £57 per ton.

The reports I receive from representatives of the engineering industries throughout the district show no material change in the position generally. Here and there, as I have previously stated, the leading establishments are fairly busy on special work, the stationary engine building trade especially being perhaps in a better position in this respect than other branches. Very few of the machine-tool makers are, however, more than moderately off for work, some of them being decidedly slack. Boiler makers are only very indifferently off for orders, and the same may still be said of locomotive builders, although rather more work has perhaps been coming forward in this branch. Altogether the outlook continues discouraging, new work generally still coming forward but very slowly, and for the most part this is only secured at extremely low-cut prices.

I had an opportunity of inspecting the other day a new design for boiler-shell drilling machines, which Messrs. William Muir and Co., of Manchester, are introducing, the machine I saw in course of construction at the works being the first of the new type that they are building. This machine, which is designed for drilling both the circular seams and the vertical butt strap holes, combines in one upright or head an arrangement of drilling tools for which two or more uprights or heads, or, in fact, two independent machines have hitherto been required to attain the same results. Briefly described, the machine, which is constructed to admit plates 6ft. wide, and boilers from 4ft. up to 9ft. diameter, consists of one upright carrying a rising and falling swivelling cross slide or arm, which can be adjusted either to the vertical position when drilling butt strap holes, or set horizontally when required to drill the circular seams. The spindles are arranged so that they can be set to point to the centre of any diameter of boiler shell, and each drill has its own automatic and quick withdrawing motion, which enables them to be operated together or independently in various positions. When the cross slide is in a vertical position a hole can be drilled 9ft. 9in. above the circular baseplate upon which the boiler shell is chucked. The construction of the machine is such that a varying number of drills can be carried as required, the one which I inspected being arranged to carry five drills, this number being regarded as preferable. The cross-slide or arm is swivelled by worm and wheel, and the driving is effected by means of a two-speed cone, bevel, and mitre-gearing, through the swivel, with spur and worm gearing for the cross-slide or arm. The upright which carries the swivelling cross slide or arm, which is balanced, can be adjusted along a bed for the various dimensions of boiler shells, and when in position is securely bolted to this bed. If desired the machine can be made duplex, with uprights opposite each other, and driven independently, and in the case of large marine boilers these are placed horizontally on adjustable rollers, and not on a table, the cross slide or arm being set vertically for circular seams, and horizontally for butt straps, two or more uprights being placed upon a long bed parallel with the boiler; in these cases the machines are made to deal with boilers up to 18ft. diameter.

We understand that Sir E. Leader Williams, the chief engineer of the Manchester Ship Canal, has accepted the presidency of the Manchester Association of Engineers for the ensuing year, which has been unanimously offered to him by the Executive Committee. Sir E. Leader Williams has for some years been an honorary member of the Association, and was asked about four years ago to accept the position of president; but at that period the heavy work devolving upon him, in connection with the construction of the Ship Canal, occupied so much of his time that he had to decline undertaking any official duties outside those connected with the important work upon which he was engaged. A promise was, however, obtained that he would be disposed to entertain the proposal immediately the canal was completed, and he has now fulfilled his engagement by undertaking the duties of president of the Association for the ensuing year.

An extremely depressed tone continues throughout the coal trade, four days per week being still the full average that pits are working, and notwithstanding this restricted output, supplies of all descriptions of fuel are in excess of requirements. The house-fire coal trade shows no material improvement, owing to the exceptional mildness of the season, and in some cases stocks are accumulating, whilst inferior qualities of fuel for house-fire purposes have here and there given way in price. For the better qualities of Wigan Arley, 10s. 6d. to 11s. represent about the average figures; with Pemberton four-foot and seconds Arley 9s. 6d. to 10s., and common house coals ranging from 7s. to 8s. per ton.

Other descriptions of fuel for iron-making, steam, and general manufacturing purposes continue bad to sell and extremely low in price, steam and forge coals not averaging more than about 6s. 6d., with engine fuel pushed for sale at almost any figure, and the lower qualities especially excessively low in price. Common Lancashire slack at the pit mouth can be readily bought at 3s. to 3s. 6d., with better qualities quoted at 4s. 6d. to 5s., and common slack from outside districts is offering at 1s. 6d. to 2s. per ton at the pit mouth, according to quality.

Only a very limited business is still reported in the shipping trade, with common round coal offering at 8s. to 8s. 3d., and the better qualities quoted at 8s. 9d., delivered at the Garston Docks or the High Level, Liverpool.

*Barrow.*—A quiet business has been done this week in hematite qualities of pig iron, and makers report a very poor inquiry generally, as well on home as on foreign account. The position of the district is adequately expressed in the fact that 1213 tons of pig iron has gone into warrant stocks this week, although only 32 out of 75 furnaces are in blast, an increase equivalent to the production of two furnaces. Stocks now represent 167,440 tons, or an increase of 72,817 tons since the beginning of the year. Prices are easy at 43s. 6d. cash net sellers, and 43s. 5d. buyers. Makers ask 44s. to 45s. for Nos. 1, 2, and 3 Bessemer, net f.o.b., but are doing no business at these figures, except in special sorts.

Iron ore is very quiet in tone, and prices are much about the same. Sales locally are small, and the home demand is quiet, and only small parcels are going away by sea.

Steel makers are rather better off for orders in the rail department. The Barrow Steel Company has booked an order for 5000 tons of heavy rails for the Indian State Railways, but this is not more than ten days' output of one mill. Rail orders generally are very few, and orders are not likely to increase until the spring of next year, when a good colonial and foreign trade is expected. Prices are easy. Steel ship plates are in fair, but not brisk demand. Local makers are sold forward for three months to come, tin-plate bars are in quiet request, and only a small trade is doing in billets and hoops, while wire rods, slabs, and blooms are neglected.

The shipbuilding and engineering trades are especially busy. The recent new orders have given a fillip to trade, which will assume a continuance of activity for a long time to come. The engine shops are very well off for orders. The engines for H.M.S. Majestic are being built at Barrow, and will be ready for delivery by the end of the year, along with the boilers, auxiliary engines, &c.

The coal and coke trades are quieter than ever. Coal is in smaller consumption at late rates. Coke from East Coast furnaces is still at 17s. delivered here.

The shipping trade shows a much quieter tone. The exports of pig iron from West Coast ports during the week amounted to 4070 tons, and of steel 1954 tons, comparing with 7189 tons of pig iron and 2954 tons of steel in the corresponding week of last year, a decrease of 3119 tons of pig iron and 1000 tons of steel. The total shipment this year to date amounted to 319,505 tons of pig iron and 355,205 tons of steel, compared with 252,033 tons of pig iron and 421,336 tons of steel in the corresponding period of last year, an increase of 67,478 tons of pig iron and a decrease of 69,131 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE coal trade still remains in the same languid condition, the pits being very poorly employed for this season of the year. Several collieries, which as a rule are well worked, had to stand idle one or two days last week. The open market is in a weak state, the business done being mainly on contract account. The increased winter demand, which is usually in full operation at this time of the year, has not yet been felt to any extent in this district. This is no doubt on account of the continued mild weather; but during the last few days cold has again set in, and this may give a much-needed stimulus to the house-coal trade. Whilst the demand is far below the average, the output steadily increases. The business in house fuel, which ought at present to be at its height, is in an unsatisfactory condition, the call for this class of fuel being only moderate. The metropolis is still taking a fair average tonnage; but sales are reported as slow, and large stocks are standing on the rails. Most merchants have stocked their coal for the winter season, and therefore do not require to buy as usual. Prices are weak, and have a tendency to further decline. Colliery owners are doing all in their power to try and maintain values; but owing to the Conciliation Board agreement, they can get no further help from the men in the way of reducing the cost of production. Although quotations are unaltered at the pits, a good deal of business is being done at lower rates.

Silkstones are from 9s. 6d. to 11s. per ton; Barnsley house, 8s. 6d. to 9s. 6d. per ton; second qualities from 8s. per ton. During last week a meeting of the South Yorkshire Steam Coalowners' Association was held at Barnsley. As usual, the proceedings were private. It was called for the purpose of considering the condition of the trade. The present demand for steam coal is exceptionally good for this period of the year, and although the closing of the Northern ports has had its effect, the supply sent to Hull and the other Humber ports is still fair. As in household sorts, the railway sidings are reported to be full of stocks of steam coal. Railway companies are at present taking a fair average tonnage on contract account, but there is little trade in other directions. Quotations for this class of fuel are unchanged, with a tendency to weakening values. Barnsley hards realise from 7s. 6d. to 8s. 3d. per ton; other qualities from 6s. 9d. per ton. Gas coal in large request at same prices as last week. Manufacturer's slack is very plentiful, prices being low and weak, and the demand quiet. At some places there are considerable stocks on hand. Pit slack from 3s. per ton; riddled slack 4s. to 5s. 6d. per ton. Smudge and small coal at low rates from 2s. or less. Coke quiet and unaltered.

Coal has been reached at Lord Masham's collieries at Acton Hall, the last 100 yards having been continually through rock. The pit was started to be sunk to the Silkstone seam, which it was hoped to find at a depth of 600 yards, and of nearly 6ft. thickness. At 330 yards the Warren house coal, 5ft. 9¾in. thick, was passed through. At 402 yards the Haigh Moor seam was proved 5ft. 11in. thick, and at 603 yards the Silkstone seam, only 17½in. thick. After this it was decided to test the lower measures, with the result that the Middleton seam was struck at 710 yards, and was also found to be 17½in. thick. It is believed that the Silkstone coal has been struck in the washed-out portion of the seam, and that it will be found on driving out from the shaft to be of the ordinary thickness both east and west.

Iron is rather depressed. Hematites are quoted at:—For West Coast brands 52s.; for North-East Coast 50s.; both delivered in Sheffield. Lincolnshire iron realises 38s., Bessemer billets £5 7s. 6d., bar iron £5 5s.

A good number of orders for railway material have of late been placed in this district, but owing to the productive powers being so large, such new business as has been added to the old hardly suffices to keep the establishments fully employed. In some instances the firms are only working a few days or alternate weeks. It is felt in business circles, however, that the bottom has now been reached, and that we may soon expect a good and steadily-increasing demand. Freights have now improved all round, and this is no doubt one of the reasons upon which the expectation of a revival in railway material is based. An increase in the railway traffic shows that much more material has been and is being made. It will also give a welcome and long looked for help towards the shipbuilding industry. The large firms of the East-end are still busily employed in the production of armour-plates for the Government. They are, however, in want of orders for boiler specialities, shafting, &c., and also require an increase in the building of passenger and merchant ships on which to place these and other productions, Sheffield being but poorly employed on this account.

Reports as to the state of the crucible steel trade are rather perplexing. We gather, however, that while many firms can find work for their hands on old orders, new orders are not coming in very freely. The Government are not placing much on ordnance account. Foreign Powers, on the other hand, are sending considerable requirements for ordnance and rifle parts.

Although the file trade is pretty active, competition remains so keen that prices leave very little margin of profit. There is a brisk request for springs for clocks, bell-sheets, ammunition parts, machine parts, &c. Penholder and pen steel is in fair demand. The wire trade is also active, but the other departments of the lighter steel trade are but poorly engaged.

The silver and electro-plate industries are in an animated condition. Manufacturers express themselves as satisfied with the season trade this year. Some firms are surprised that it has turned out so well, and it is, in fact, well up to the average of previous years. The cutlery trade has also been good. The skilled artisans at present out of employment are only few. The demand has mainly been for case goods, which are sent mostly to the States.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

IN no branch of trade in this district is there any sign of improvement, and the tone of the market generally is very despondent, the opinion being that a hard winter is in store for manufacturers, with irregular work and unprofitable prices. The quietest period of the year has to be passed through, and not before the spring is it considered likely that a change for the better will make its appearance. The prospects of a dull winter cause competition among producers to be very keen, for they are anxious to secure without delay work enough to enable them to keep their mills employed with some approach to regularity, even though they have to accept prices which will leave them with no profit. But they think that if they have to wait they will have to take still lower prices, and may have still greater difficulty in getting orders, for the reports concerning the prospects of all industries concerning iron and steel are very discouraging. Capitalists seem to have no confidence, and keep their money locked up in Consols, banks, and other safe places, even at very low rates of interest, rather than risk it in trade enterprise. Consols accordingly are realising higher prices, while the shares of all companies connected with trade are obtainable at lower prices than were taken a short time ago. The only satisfactory feature in the trade of this district this month is the heavy shipments of pig iron from the Tees. As a rule, November is a time when deliveries by sea are comparatively small—in fact, they are usually almost the poorest in the twelve months—but this year they are likely to be the best of any month in the year.

Taking November of the last six years the average exports have been about 70,000 tons, but this month they considerably exceed that. Up to Wednesday night the quantity was 78,583 tons, as compared with 71,053 tons last month, and 60,977 tons in November last year, all to 28th. There has also been a very large shipment of Cleveland iron from Skinningrove—nearly 8500 tons. Under these circumstances it is expected that stocks of Cleveland pig iron will show a decrease for November—the first decrease since May—but the extent of that decrease cannot well be estimated, as there is no information as to how much of the pig iron shipped has been of hematite quality. It can hardly be doubted that the stocks of hematite pig iron have increased, but as no statistics of the hematite stocks are collected it is impossible to gauge the extent of the hematite pig unsold in makers' hands. It may be expected that the stock will continue to increase during the winter if some reduction in the production is not made, for the prospects of the steel trade at home are very poor, and there must be a considerable falling-off in the shipments on account of the closing of some of the ports to which hematite pig is forwarded rather largely. It would seem to be the best policy to blow out some of the furnaces making hematite iron. A smaller make would enable producers to keep up their prices better, and it would, moreover, probably bring about some reduction in the cost of production, which is now out of proportion with the selling price of the iron. Consumers complain of the prices of coke and ore, but as long as the demand continues for them it is not likely that sellers will bring down their rates. The blowing-out of some of the furnaces would lessen the consumption of materials, and this would have its effect upon prices thereof.

Consumers have been able to buy No. 3 Cleveland G.M.B. pig iron this week for prompt f.o.b. delivery at 35s. 6d., and they are ready to pay that also for deliveries to be made over the first quarter of next year, but they found very few producers ready to sell forward at that rate. They would, however, have had little difficulty in buying at 35s. 9d. forward. Cleveland warrants have been bought, and rather more freely than usual, and 35s. 8d. cash has been paid for them, but Wednesday's close was at 35s. 5½d. cash. The stock of Cleveland pig iron held in Connal's warrant stores on Wednesday night was 90,478 tons, or 1847 tons increase this month. Taking into account the large shipments, and the reported scarcity of No. 3 in makers' hands, a considerable decrease in the stock of the stores might have been expected. Grey forge pig iron could readily be got at 33s. 7½d. Though Mixed Nos. of East Coast hematite pig iron have all the week been quoted at 42s. 9d. per ton, yet buyers have had no difficulty in getting some brands at 42s. 6d. Yet neither ore nor coke is becoming cheaper, and are realising almost as much as they did when hematite pig was 3s. 6d. a ton higher. Cleveland basic iron No. 3 is worth about 37s. 6d., but there is not much being offered for sale.

Trade is very unsatisfactory in the finished iron and steel industries, and the lower prices fail to draw business. Steel plates are 10s. per ton cheaper than they were in September, but shipbuilders are so badly situated that they cannot see their way to order even at the present low range of prices. Both iron and steel ship-plates are at £4 12s. 6d., less 2½ per cent., f.o.t., and iron and steel angles are at £4 10s., less 2½ per cent., f.o.t.

Bar makers feel the depression less than any of the other manufacturers, and they are getting better prices for their goods, while there is no competition with steel with which to contend. The official returns indicate that considerably more has been paid of late for bars than for any other leading description of finished iron. At Thornaby-on-Tees, Mr. Hopper, who has been connected with the late Sir George Elliot's rope works in South Wales, is about to start a steel-wire rope-making establishment, and has secured for the purpose part of the brewery of Messrs. Knights, Stocks, and Co.

The directors of Dorman, Long and Co., Britannia and West Marsh Steel and Ironworks, Middlesbrough, report a profit for the year ending September 30th of £13,707 15s. 0d., but after paying interest on debentures, directors' fees, income tax, &c., they are unable to pay any dividend to the ordinary shareholders. They state that the moulders' strike, which lasted over six months, seriously diminished the demand for finished steel, and materially affected the year's operations. The directors took advantage of the strike to close their works for a time in order to make additions to the plant and appliances of No. 3 mill. They believe that this will enable them to meet the increased competition of the day with better effect. Over £9000 has been spent in thus adding to the plant; they have laid down live roller gear in one of the mills, electric lighting and driving plant in the engineering departments, automatic feeders to gas apparatus, &c.

The statistics of Mr. Waterhouse showing the deliveries of manufactured iron and the net average prices realised for the two months ending October 31st have been presented to the Board of Conciliation. The summary is as follows:—

| Description. | Weight invoiced. | | | | Percentage of total. | Average net selling price per ton. | | |
|---|---|---|---|---|---|---|---|---|
| | Tons. | cwt. | qr. | lb. | | £ | s. | d. |
| Rails .. .. | 728 | 1 | 1 | 7 | 3·02 | 4 | 9 | 0·80 |
| Plates .. .. | 8,726 | 15 | 2 | 19 | 36·16 | 4 | 13 | 11·59 |
| Bars .. .. | 10,940 | 2 | 0 | 2 | 45·33 | 5 | 2 | 11·71 |
| Angles.. .. | 3,735 | 17 | 3 | 22 | 15·49 | 4 | 14 | 7·63 |
| | 24,130 | 16 | 3 | 22 | 100·00 | 4 | 18 | 0·07 |

It is curious to note that, while the values of each description of iron have varied considerably from the previous return, yet the total average is only 0·15d. per ton—three-twentieths of a penny less. The price of iron rails showed an increase of 2s. 7·29d. per ton; that of plates a decrease of 7·92d.; that of bars an increase of 1s. 1·99d.; and that of angles a decrease of 11·14d. The total average is one-half greater than it was in the corresponding period of last year, and is 2s. per ton better than it was at the commencement of the year. The production in September and October was 2500 tons greater than in the previous two months. In accordance with the sliding scale, the wages of finished ironworkers will remain unchanged for December and January. There has been no alteration in them since the end of February.

The shipbuilding industry is much depressed, especially on the Tyne. Comparatively few orders have been received this quarter, and a slack winter is almost certain. Not since 1885 has there been so little work in hand or so many men out of employment. Only a few of the engineering establishments have a fair share of orders, and inquiries are much less numerous than they usually are even at this period of the year. The prospects of better times are not encouraging. The pattern makers in the North of Eggland, after being on strike for eight months for an advance of 3s. 6d. per week in wages, have at length bowed to the inevitable, and abandoned their claim. Those for whom work could be provided resumed operations on Monday, but there are many who still have to remain idle. Many of the moulders also have not been able to get work since their strike ended. Both of these classes of workmen will now see the futility of striking for an advance in a falling market.

Mr. Thomas Bell, the last surviving brother of Sir Lowthian Bell, died in Switzerland a few days ago. In 1850 the deceased became partner in the Walker Ironworks, and was also associated with his brothers, Sir Lowthian and Mr. John, in the ironworks at Wylam, Washington, and Clarence, as well as the Walker Chemical Works. Mr. Thomas Bell managed the Walker Rolling Mills till they were closed, after which he went to Bilbao. He was largely instrumental in bringing into use the salt brine in the Middlesbrough district. When travelling in the neighbourhood of Navey in France he noticed a simple appliance for drawing water from a considerable depth. The idea was utilised and improved upon, and is now generally adopted in the Teesside industry.

The coal trade is becoming duller, and work at the mines is not so regular. This being so, the Durham miners have wisely decided not to press their application for a 15 per cent. advance of wages, but have withdrawn it. They recognise that there is not much chance of securing an advance in a falling market. The establishment of a Conciliation Board for the Durham coal trade is almost accomplished, the rules having been approved by both sides, and for the next two years at least will regulate wages and other questions.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a rather more firm feeling in the pig iron market, with a moderate business doing. While the turnover of warrants is not very large, prices have hardened somewhat in the last few days. Scotch warrants improved 2s. to 3s. per ton, and Cleveland iron was also a little better, and a steadier feeling likewise pervaded the hematite market. It is considered probable that, as has not infrequently happened in former times, business may improve to some extent towards the close of the year.

The output of pig iron has been steadily increasing, and is now much larger than it was twelve months ago. Stocks had, however, become very light during the strike in makers' yards, and there had been a large decrease in the warrant stores. For this reason an extended output may very likely have little effect upon the market for some time. There are now sixty-seven furnaces in blast —forty-four turning out ordinary iron and twenty-three hematite —compared with forty-five at this time last year.

The following are the current prices of makers' iron:—G.M.B. f.o.b. at Glasgow, No. 1, 43s. 9d.; No. 3, 42s. 2d. per ton; Monkland, No. 1, 45s.; No. 3, 43s.; Carnbroe, No. 1, 45s. 6d.; No. 3, 44s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s.; Gartsherrie, No. 1, 51s. 6d.; No. 3, 47s. 6d.; Calder, No. 1, 52s.; No. 3, 48s. 6d.; Summerlee, No. 1, 53s.; No. 3, 47s. 6d.; Coltness, No. 1, 55s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 52s.; No. 3, 48s. 6d.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 3d.; Dalmellington at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts at Leith, No. 1, 55s. 6d.; No. 3, 50s.

The shipments of pig iron from Scottish ports in the past week amounted to 5103 tons, against 4489 in the corresponding week of last year. There was despatched to Germany 911 tons, Australia 620, Italy 423, Canada 15, India 263, France 20, Holland 155, Belgium 76, Spain 52, China and Japan 350, other countries 110, and coastwise 2108, against 2603 in the same week of 1893.

The finished iron and steel branches are quiet. There is at the same time a slightly improved feeling observable this week. What may come out of it it is impossible to say. The malleable iron department shows a little more activity in various articles, with somewhat steadier prices. There is, however, much room for improvement. The output of steel has been increasing, and is mainly for use in the shipyards.

The exports of manufactured iron and steel, which have declined to very small proportions, now begin to exhibit some expansion. The shipments from Glasgow in the past week embraced locomotives to the value of £28,500; sewing machines, £12,255; other machinery, £18,192; steel goods, £10,923; and miscellaneous iron goods, £37,896.

Messrs. Neilson and Company, of Glasgow, have booked orders for thirty-two locomotive engines, and twelve duplicate boilers for the East Indian Railway Company. The locomotive branch is now very fairly supplied with work.

Some fair orders are reported to have been obtained in the course of the last few days by Clyde shipbuilders and marine engineers. Arrangements are now being made for a large extension of the premises of Messrs. Russell and Company, shipbuilders, Port Glasgow.

The coal market is easier all round. The shipping trade in coals has fallen off considerably, partly owing to unfavourable weather at sea interfering with the sailing of vessels. The shipments of coal from the Scotch ports in the past week amounted to 134,637 tons, being 13,333 less than in the preceding week, and 36,442 below the clearances for the corresponding week of last year. In the home trade there is a fair consumption, but the supplies are now very full, and more than equal to all requirements, so that it is difficult to maintain the prices.

Nothing has come of the attempted agitation by the miners' leaders for an advance of wages. The proposal was obviously inopportune. The great body of the miners are evidently of this opinion, for they have given no active support to the movement sought to be promoted by their leaders.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THERE is more quietness in the steam coal trade than is approved of on 'Change, both at Cardiff and Swansea. Prices at Cardiff kept up tolerably well until mid-week, when the quotations which had been 11s. 3d. to 11s. 6d., subsided down to 11s. 3d., and the demand evidently flagging. While best coals remained with only a slight falling off in firmness, seconds and inferior coals generally, exhibited greater weakness than usual. I give Cardiff quotations as last issued, closing prices, mid-week:—Best steam coal, 11s. 3d.; seconds, 10s. 6d.; dry sorts, 9s. 6d. to 9s. 9d.; best Monmouthshire, 9s. 3d. to 9s. 6d.; best small, 5s. House coal, which is in moderate demand, is selling at Cardiff as follows:—Best households, 10s. 9d. to 11s.; No. 3, Rhondda, 10s., brush, 8s. 3d.; small, 6s. 9d.; No. 2, Rhondda, 8s. 3d.; through, 6s. 3d.; small, 4s. 3d. Pitwood is still scarce, prices:—18s. 6d. to 20s. 6d. Patent fuel, 10s. 6d. to 11s. Coke, furnace, 14s. to 15s.; foundry, 15s. 6d. to 16s.; special foundry, 21s.

The effect of the unsettled condition of the colliers, and the certainty that the sliding scale will come to an end, are already beginning to tell, and that in a ruinous manner, as the colliers, I am sorry to add, will soon know to their cost. I am told upon excellent authority that one coalowner has declined an Admiralty contract of 20,000 tons, simply because he has no faith in the men. In several districts the hauliers are reported to be only waiting their time, and the slightest alleged grievance leads to a stoppage. A colliery manager of great experience, now retired from practical management, remarked lately that he was only too happy to be out of it. "The time is at hand when colliers will be asked as a favour to go down into the workings." A leading manager still at the "helm" coincides with this, adding, "I often have half an hour's discussion at the top of the pit before the men will descend."

One large colliery last week was only at work two days, and another three and a-half days. Colliery gatherings have been held of late for the purpose of arranging about future organisation. The last conference of colliers' representatives was held at Aberdare on Tuesday, Mr. D. Morgan presiding, and Mr. Brace in the vice-chair. At this meeting it was decided that workmen form themselves into an Association for the purpose of organisation; that, beginning with the new year, adults pay one shilling per month, and boys sixpence per month, and that the workmen pay them direct and not through the several colliery offices. With regard to the drawing up of rules, this is to be undertaken by a committee of eleven. It remains to be seen how far this Association will be carried out, with "Mabon," Mr. Abrahams, M.P., taking independent action.

The iron and steel trades remain in a very stagnant condition. Rails are in feeble demand, and tin bar, consequent upon the state of the tin-plate trade and wage discussion, has fallen off considerably. In addition to this large cargoes of pig continue to arrive from Middlesbrough and Harrington, making the situation worse.

The latest news from the tin-plate districts is that there is just a possibility of workmen coming to terms with the employers, and making such concessions as will enable the works to be carried on. Meetings have been held without coming to a final decision, and the last was adjourned until next week, when it is to be hoped that a common-sense conclusion will be arrived at. I am glad to hear that at one or two works the men have agreed to concede a reduction. At a few work this week is practically nil, and though the old quotations remain, they are simply nominal. It was stated on 'Change, Swansea, this week that orders offered were on such a basis as to leave a serious loss to makers, and that many leading tin-plate manufacturers regard the alternative of closing, for a time at least, as the better course.

Swansea quotations this week are as follows:—Pig iron market perceptibly weaker. Glasgow warrants, 42s. 6d. cash buyers; Middlesbrough No. 3, 35s. 5d. prompt; hematite, 43s. 5d; Welsh bars, £5 2s. 6d.; sheet iron, £6 to £6 10s.; sheet steel, £6 5s. to £6 10s.; steel rails, £3 15s. to £3 17s. 6d., heavy sections; light, £4 7s. 6d. to £4 10s. Bessemer steel: Tin-plate bars, £4; Siemens best, £4 to £4 2s. 6d. Tin-plates: Bessemer steel cokes, 10s.; Siemens, 10s. 3d. to 10s. 6d.; ternes, 28 by 20, 20s. to 24s.; best charcoal, 11s. 6d. to 12s. 6d.; wasters, 6d. to 1s. less. Block tin is now quoted at £62 12s. 6d. to £62 15s.; patent fuel, 10s. to 11s. Iron ores: Tafna, 11s.; Rubio, 11s. 3d. to 12s. Coke, from 12s.; furnace and best foundry, from 17s. 6d.; pitwood, 20s.; anthracite, 12s. to 12s. 6d., best vein; ordinary, 8s. 9d. to 9s. 6d.; small rubbly cokes, 4s. 6d.

The dockising of the river Avon is again to the front at Bristol. This week at a meeting of the Bristol Dock Board a member proposed rescinding the resolution of July last against carrying out the dockisation of the river Avon. The chairman pointed out that it was practicable for any member to propose a new scheme, for port improvements, including dockising, and the member, Mr. Deridder, withdrew his motion, so as to retain liberty of action.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

BUSINESS in the different branches of the iron and steel trade has been remarkably quiet all through last week; very few contracts are being secured, and the situation of makers and manufacturers is, in some instances, getting worse instead of better

In Silesia the condition of the iron and allied trades is exactly the same as before; pig iron meets with poor request, and manufactured iron is, generally, also but weakly called for. Quotations are as low and unpaying as ever. The prolongations of the Silesian Rolling Mill Convention till end of 1895 has not had the desired stiffening influence on prices; on the contrary, makers have come to the conclusion that unless they offer their articles at prices below those of the Belgian and German firms, they are not likely to get any orders at all, and so the works willingly agree to pretty large concessions. In hoops and in some special sorts of structural iron, a comparatively fair business has been transacted upon the week. There is nothing new or specially interesting to note concerning the state of the iron business in Austria-Hungary. For the present producers and consumers report themselves pretty well satisfied with quotations and demand, the majority of the works maintaining a regular activity. Quotations are, as a rule, firm, although for large orders makers do not hesitate to accept prices which are considerably below list rates. Inland works actually have to fight for orders, as the Rhenish-Westphalian firms continue to throw large quantities of iron on the Bohemian, Galician, and Hungarian market; at a recent tendering for railway requirements, a Rhenish-Westphalian works, underquoting the inland makers, got the contract.

Demand and employment on the French iron market continue irregular. In the Haute-Marne districts iron business slowly tends towards improvement, while in Paris quotations show considerable weakness. The works of the Department Nord all complain of a scarcity of new orders and a consequent increase in stocks, which compels them to considerably restrict their output.

Belgian iron industry begins to be slowly influenced by the advancing winter and the closing of the Baltic ports, which always causes a decrease in consumption. Foreign trade, especially that to the East, has been very dull lately; nevertheless, statistic figures for the first nine months of present year are, on the whole, rather favourable. Total export of finished iron, for instance, shows an increase of 39,000 t., against 1893. In steel manufactured goods import, on the other hand, has increased by 30,000 t. Export in pig iron shows a decrease of 5000 t.; in iron ore 176,504 t. were exported, against 123,423 t. in the year before. At a recent tendering for 15,000 t. steel rails for the State Railways, Belgian works succeeded in securing the contract at 119·90f. p.t., Krupp Essen offering at 123f. p.t., while most of the foreign works asked 125f. p.t. On the Belgian coal market only a quiet business has been done for some time past, the demand for house coal being flat, The cold weather which has now set in cannot, however, fail to cause a general increase in demand, and a stiffening tendency in quotations will follow. Engine classes of fuel are firm, especially in the Liège district, while from Hainault the reports are rather unfavourable, some of the leading coalowners of the centre, Mons and Charleroi district, having proposed to stop on Monday and to reduce wages 5 to 7 p. c. Regarding the Belgian business in coal during the first nine months of the year, import in coal is stated to have been 1,003,653 t. this year, against 951,907 t. in the preceding year, of which 448,790 t. came from Germany, against 410,907 t. in 1893. Import in coke was 240,615 t., of which 232,994 t. fell to Germany, 50 t. to England, 6844 t. to France, and 727 t. to the Low Countries; in 1893, 183,694 t. were imported, of which no less than 178,580 t. came from Germany. Export in coal shows a decrease of 160,000 t., or 5 p.c., against last year, 3,209,611 t. only being shipped against 3,370,835 t. in 1893; Germany bought 163,680 t., against 169,195 t.; while to France 2,535,480 t. were exported, against 2,672,531 t. in 1893, which is equal to a decrease of 137,000 t. Total export in coke amounted to 651,152 t., against 682,053 t. in previous year; to Germany 118,008 t. were sent, against 107,950 t. in 1893. Export to France and Luxumburg shows a considerable falling off. According to statements published by the Minister of Public Work, output of the Belgian collieries was, in 1893, 19,410,519 t., worth 181,405,900f., which shows, compared to the preceding year, a decrease of 172,654 t. in quantity, and in value a decrease of 19,883,100f. The number of men employed was 116,861 in 1893, being 1717 less than in the year before. The number of women employed has decreased by 1519. Wages paid amounted to 103,648,600f., so that average pay was 3·06f. per day; yearly wages being 887f. Actually, however, 871f. per cent. only were given after the usual deductions, against 957f. that were paid in 1892, which shows a decrease of 74·10 per cent. on the annual wages, and 7 per cent. on daily wages.

The unfavourable condition of the Rhenish-Westphalian iron industry continues. Considering the extremely small demand that is coming forward for all descriptions of iron, it is rather astonishing that prices have remained comparatively firm. Spiegeleisen, 10 to 12 p.c. grade; notes M. 52 p.t.; Rhenish-Westphalian forge pig No. 1, M. 46 to 47 p.t.; No. 3, M. 40 p.t.; Siegerland quality, M. 44 p.t. Hematite is being offered at M. 63 p.t.; foundry pig, No. 1, costs M. 63; No. 3, M. 54 p.t.; basic stands at M. 45 p.t. German Bessemer fetches M. 50 to 51 p.t. For Luxemburg forge pig 48f. p.t. is still the price officially quoted. The situation of the malleable iron market is even more unfavourable than that of the pig iron trade. Quotations have been reduced to such a degree that some of the larger mills were obliged to limit their working hours and to dismiss a number o their men.

The scarcity of fresh orders is particularly felt at the steel works and construction shops, one works having given notice to about 500 men. The tube foundries, which had hitherto been well engaged, also begin to complain, prices being fluctuating and far from paying.

Latest list quotations, per ton at works, are as follows:—Good merchant bars, M. 100 to 105; rivet iron, M. 125; angles, M. 110 to 115; girders, M. 90 to 93; hoops, M. 108 to 113; billets in basic and Bessemer, M. 73 to 77; heavy plates for boiler-making purposes, M. 140 to 145; tank do., M. 130 to 135; steel plates, M. 120 to 125; tank do., M. 110 to 115; sheets, M. 140. Siegen thin sheets, M. 125. Iron wire rods, common quality, M. 115 to 120; wire nails, M. 115 to 120; rivets, M. 145 to 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 110 to 120; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230.

The total production of pig iron in Germany, including Luxemburg, was, for month of October, 1894, 490,934 t., of which 133,035 t. were forge pig and spiegeleisen, 32,508 t. Bessemer, 241,181 t. basic, and 84,210 t. foundry pig. Production in October, 1893, amounted to 437,183 t. in September, 1894, it was 473,070 t. From January 1st to October 31st, 1894, 4,579,180 t. were produced, against 4,084,056 t. for the same period the year before.

I regret to record the death of Herr Hendschel, of Kassel, owner of the well-known locomotive and machine shops. Herr Hendschel, who was only fifty seven years of age, died of inflammation of the lungs.

BORDEAUX EXHIBITION.—A meeting of the committee which has been appointed by the Council of the London Chamber of Commerce to further the success of this Exhibition was held at the office of that Institution on the 21st inst., under the presidency of Sir Albert K. Rollit, LL.D., M.P. Those present included Sir Walter Gilbey, Sir Bernhard Samuelson, M.P., Sir Charles M. Kennedy, Messrs. Henry V. Trapp, Paul Albert, R. W. Fithian, Ernest Clarke, E. Burney Young, and others. It was reported to the committee that the executive of the Bordeaux Exhibition did not propose allocating space for international sections, but that if any desire were expressed for the formation of a British section, proper accommodation might be provided in a separate annexe. Sir Bernhard Samuelson suggested that the committee agreed that it would probably be more satisfactory to adhere to the intentions of the Bordeaux Executive in classifying the goods of all nations according to groups. The Secretary of the Chamber of Commerce is, by direction of the committee, communicating with the Bordeaux executive as to the appointment of a British committee in Bordeaux who will protect the interest of British exhibitors. All applications for space must be lodged not later than the end of December. The Secretary of the London Chamber of Commerce at Botolph House, Eastcheap, E.C., will give particulars.

THE IMPERIAL INSTITUTE.—The greatest Photographic Exhibition which this country will have ever seen has been planned by the Executive Council of the Imperial Institute, to be held at South Kensington in the summer of 1895. The Exhibition will include seven divisions, namely:—(1) Artistic photography. (2) Historical photography. (3) Photography in its application to industries. (4) The application of photography to sciences, including chromatics, optics, stereoscopy, photomicrography, spectroscopy, meteorology, magnetism, astronomy, automatic recording apparatus, and so on. (5) Applications of photography to educational purposes. (6) Miscellaneous applications of photography, including engineering, architecture, archæology, military and naval purposes, legal purposes, surveying, cartography, and chronography. (7) Photography as an industry, including the apparatus used in photography, the stages of the manufacture of lenses, the making of brass fittings and cameras, shown in actual operation; the preparation of dry plates, the coating by sensitive media, printing processes, reproduction of pictures, and the production of portraits by daylight and artificial light. The Governor-General of India, the Governor-General of the Dominion of Canada, and the Governors of the various Colonies, have been requested to invite Indian and Colonial manufacturers to exhibit.

JUBILEE OF AN EMINENT SHIPBUILDING FIRM.—The present is the jubilee year in the history of the well-known firm of William Denny and Brothers, Leven Shipyard, Dumbarton, and the event is about to be fittingly celebrated in that busy little port. The workmen and officials in the Leven yard, backed up by the townspeople generally, are bestirring themselves to mark in some tangible way their sense of the importance of the occasion, and their goodwill towards, and admiration of, Dr. Peter Denny, the head of the concern and one of its founders. A further interesting fact is that next year Dr. and Mrs. Denny—the latter of whom is as great and admired a figure in the social and domestic life of Dumbarton as that of the doctor himself in industrial and commercial circles—will celebrate their golden wedding. Having this in view, as well as the jubilee of the firm, various proposals are being canvassed as to a fitting and lasting memorial of the double event. While the firm under its present designation has only been in existence fifty years, that period, of course, does not represent the length of time during which the name of Denny has figured prominently in the annals of shipbuilding on the Clyde. It has been closely and honourably allied with the industry almost since the beginning of the present century, the business having about that time been founded by William Denny the elder, father of the present Dr. Denny. From his unpretending yard, on a site on the opposite side of the Leven from the present large works, were launched, amongst other large vessels, the Marjory and Rob Roy, both of which took a notable part in the early development of steam navigation. Dying in 1833, William Denny left behind him seven sons, all trained in shipbuilding, three of whom, William, Alexander, and Peter, obtained joint possession of the family yard, and launched into iron shipbuilding under the designation of William Denny and Brothers. In 1843 they removed to the present site, and were soon in the thick of work for the most enterprising of the early steam shipping companies. About eight years after removal to the Leven shipyard, Mr. Peter Denny, through the decease of his brothers, found himself sole partner of the firm. In 1851 he, with others, established the distinct engineering business of Denny and Co., the managing partner in which for many years has been Mr. Walter Brock. In 1868 Mr. Peter Denny assumed as partner in the shipbuilding yard Mr. William Denny, his eldest son, whose untimely death at Buenos Ayres in March, 1887, is still acutely lamented. At the present time the company partnership consists of, besides Dr. Denny, Messrs. Walter Brock, Peter Denny, jun., John Denny, Archibald Denny, and John Ward. The firm have built during the past fifty years close on 450 vessels, large and small, aggregating some 550,000 tons, and comprising steamers—sailing ships have been all along out of their line—of all kinds, from capacious deadweight carriers and powerful mail and screw passenger steamers to swift channel paddle steamers and light-draught river boats, shipped abroad in pieces.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, November 22nd.

The manufacturing interests have yet shown very little signs of recovery from the depression induced by the economic measures agitated by the present administration. Prices in iron and steel continue low. Steel billets are 15·50 dols. at Pittsburgh; 18 dols. at Philadelphia; bridge iron 1·15 dols. upwards at mill; tank steel, 1·10 dols. in large orders; steel rails, 24 dols. A difference of 8 dols. and over between billets and rails is not considered one that can be maintained as soon as one or two elements of competition assert themselves. Much new work is in sight, but it cannot be pushed at present. The rolling mills are running to about 65 per cent. of capacity. The commercial situation has not improved. The action of the Government in borrowing money when its own people are willing to support it is unfavourably considered. Coal production is steadily increasing. Shop work is more abundant than for a year. An improving demand will probably spring up about midwinter for machinery and equipments of all kinds for spring use.

## RECENT OBSERVATIONS ON ELECTRICITY IN COAL-MINING.*

By Elmer A. Sperry.

In this paper the author briefly summarises the advances that have been made in the United States during the present year, some under his personal supervision or observation, in the application of electricity to coal-mining.

Improvements in electric haulage have been largely in the direction of giving increased flexibility to the wheel-base, and rendering the same more complete. To obtain perfect adhesion on a mine track, which, from many causes, becomes very uneven, the wheel-base should be entirely flexible, dividing up the total weight of the locomotive so as to distribute an equal amount upon each driver contact. This was at first only partially accomplished by a spring over the journal housing from a rigid frame. It has latterly been found that a system of links and rockers somewhat similar to those used in the latest construction of heavy freight locomotives in America is the best arrangement for electric haulage cars in mines. The mechanically coupled driver has been found to be far superior in tractive effect, the tendency of one driver to slip being checked by all the others instead of by its fellow only, as is the case where separately driven axles are employed. For average conditions the locomotive is, in the author's opinion, the best system of haulage. Where heavy grades in mines exist against the loads, say, from 5 per cent. upwards, and in many other instances, and endless or a tail-rope haulage may be found preferable to electric haulage; but either of these older systems may in most cases be electrically driven with great saving over compressed air or steam.

The author gives the following rule for determining the proper rail section where electric locomotives are used in coal mining: Divide the weight of the locomotive resting on the drivers in tons by the number of drivers; for dry entries, multiply the number so obtained by 12½, and for wet entries by 15; this gives the number of pounds per yard of rail that should be employed for the best effect.

Amongst the latest improvements in electric long-wall coal cutters is a specially low type for thin seams, involving the use of a much more powerful motor than has heretofore been applied to this class of machinery, the capacity for power having been increased 75 per cent. This has necessitated a heavier and stronger cutting mechanism, and steel gearing throughout. Trouble from moisture in and about the electrical part of the machine has almost totally disappeared. The method of holding the knives or cutters has been improved, necessitating a new form of cutter. The width of the machine has been kept under 24in., allowing the props to be used in close proximity to the face, and rollers have been provided upon the machine for passing the rails from the rear to the front of it, after the machine has travelled along the rails. Other improvements are noted, among which is the new removable truck which has been devised for running the machine upon the mine track when changing it to the point of starting in with the cut.

Very little advance has been made in the past year in breast machines, which have many weak points.

The pick machine has recently undergone considerable change in detail, strengthening of the main structure, &c. It strikes a heavier and more effective blow than the same class of machine operated by compressed air; and the author is of opinion that it will be found to fulfil the requirements and to be of general service in and about a mine, among sulphur balls and in hard ground, and under conditions in which other machines cannot be employed.

Improvements in dynamos during the present year have been in matters of smaller detail, tending to increase the output per given weight of machine and rendering it more durable and stable. A special mine-type of dynamo is preferable to the ordinary type in having fewer delicate parts, and being in general less liable to derangement, and designed for specially hard service through any number of hours per day.

**New Swindon Junior Engineering Society.**—A large number of the members of this society attended a meeting at the Mechanics' Institute, New Swindon, on Saturday, the 24th inst., to hear a paper on "Liquid Fuel, with reference to Holden's system," by Mr. J. H. B. Jenkins, F.C.S., of the Stratford Works. Passing from an account of the origin of liquid fuel systems in Great Britain, Mr. Jenkins described Crow's system, which consisted of the evaporisation of the oil in pipes acting as retorts in furnaces. with the aid of a very large diagram of the famous G.E.R. locomotive Petroleo, and sectional drawings of the special injectors, Mr. Jenkins was able clearly to define the principles of Holden's liquid fuel system, carefully tracing out the arrangement of pipes and, in fact, every detail.

22,305. Wagon Tarpaulin, &c., A. and W. Purvis, Glasgow.
22,306. Detachable Sconce for Lamp, W. W. Hare, London.
22,307. Metal Ends of Neckties, D. Cutler, Birmingham.
22,308. Bricks for Fireproof Buildings, C. G. Picking, London.
22,309. Production of Printing Blocks, C. Crabbe, London.
22,310. Thimbles, S. H. James, London.
22,311. Railway-signalling Appliance, H. L. Peters, Surrey.
22,312. Lifting Plates from Ovens, G. Henshall, S. Thompson, R. Crabtree, and F. Nuttall, London.
22,313. Railway Carriage, &c., Doors, R. Dakin, London.
22,314. Cigar-ash Trays, J. Fitton, Manchester.
22,315. Window-sash Fasteners, J. C. Craine, Manchester.
22,316. Method of Evaporating Brine, R. Pearson, London.
22,317. Cranks and Pedals of Cycles, G. P. Mills, London.
22,318. Cream Separators, P. Withers.—(*A. Helzel, Italy.*)
22,319. Screw-nuts, J. L. Wiles, London.
22,320. New Game, J. C. Willis, London.
22,321. Tools, &c., E. Roberts and C. W. Whitham, London.
22,322. Pneumatic Tires for Vehicles, J. Litherland, London.
22,323. Producing Spiral Mouldings, W. Osment, London.
22,324. Locks and Keys, J. K. Oldfield, London.
22,325. Fuses for Electric Light Wire, R. G. Tyler, London.
22,326. Frames of Bicycles and Tricycles, R. J. White, London.
22,327. Covering for Street Manholes, W. Denton, London.
22,328. Cycles, C. Tarling, London.
22,329. Washing and Cleansing Grain, E. A. Weinhold, London.
22,330. Fire-lighter, F. Schusterbauer, London.
22,331. Velocipedes, H. C. Field and A. W. Storey, London.
22,332. Curative and Nourishing Emulsion, T. Jardine, London.
22,333. Perforating Patterns in Leather, T. Lewis, London.
22,334. Brakes, A. J. Boult.—(*Fahrendeller Hutte-Winterberg and Jüres, Germany.*)
22,335. Manufacture of Boots, C. H. and F. J. Dale, London.
22,336. Fastening Neckties, W. P. Thompson.—(*W. Bohnhoff, Germany.*)
22,337. Inkstands, J. W. Young, London.
22,338. Wrenches, W. E. Pugsley, London.
22,339. Construction of Washing Machines, A. J. Askew, London.
22,340. Multipolar Dynamos, G. L. Addenbrooke, London.
22,341. Exposing Tea or Coffee to the Air, S. C. Davidson, London.
22,342. Steam Generators, T. L. and T. J. Sturtevant, London.
22,343. Miner's Lamp, C. Dahlmann, London.
22,344. Funnels, H. I. Keiner, London.
22,345. Ratchet Brace, P. R. J. Willis.—(*A. Taylor, United States.*)
22,346. Chiming Clocks, P. R. J. Willis.—(*T. Sargant, Canada.*)
22,347. Roller-grinding Machines, G. Eckhardt, London.
22,348. Flushing Cisterns, R. B. Evered and N. Coleman, London.
22,349. Steam or other Fluid Engines, W. H. Scott, London.
22,350. Ventilators, R. Lofthouse, London.
22,351. Bicycles, &c., R. Haddan.—(*F. Thouin*, ——.)
22,352. Fire-escape, C. Rajot, London.
22,353. Flange Packings, J. P. Gauthier, N. Henriot, and A. Jourdanet, London.
22,354. Strap Buckles, C. Rohte, London.
22,355. Saddle Covers for Bicycles, W. L. Loveridge, London.
22,356. Spirit Stoves, H. H. Leigh.—(*E. Garnier, France.*)
22,357. Kilns for Drying Bricks, &c., J. Craven, London.
22,358. Playing Stringed Instruments, E. Dansaert, London.
22,359. Wheels for Velocipedes, &c., A. Mortera, London.
22,360. Gear Cases for Velocipedes, P. Hunaeus, London.
22,361. Pickling, W. S. Rawson and Woodhouse and Rawson United, Ld., London.
22,362. Railway Signalling, A. Richard and N. Gray, London.
22,363. Oxidised Lead Process, A. Gutensohn, London.
22,364. Weighbridges and Machinery, A. Aeffcke, London.
22,365. Watch Dials, T. C. Hailey and P. C. Hamilton, London.
22,366. Textile Fabrics, E. Esser and P. Scheider, London.
22,367. Binder for Music and other Sheets, H. Hill, London.
22,368. Tile, G. Czerwonky, London.

*20th November*, 1894.

22,369. Paint Pots and the like, C. R. Gorringe, London.
22,370. Paint and other Brushes, C. R. Gorringe, London.
22,371. Signal Apparatus for Railways, J. A. F. Hall, Brentford.
22,372. Bobbins and Carriages, E. Whitworth, Nottingham.
22,373. Knitting Machinery, &c., G. F. Sturgess, Leicester.
22,374. Miners' Safety Cage, J. Knox, Durham.
22,375. Rain Protectors for Vehicles, A. Eckford, Leith.
22,376. Disinfecting, P. E. Singer and J. Enright, London.
22,377. Winding Thread, A. G. Brooks.—(*J. W. Foster, United States.*)
22,378. Rotary Engine for Locomotives, G. Bewick, London.
22,379. Tobacco Pipe, J. McLaren, Dersingham.
22,380. Reducing Breakage of Coal, S. Tate, Newcastle-on-Tyne.
22,381. Ball-bearing Axles for Vehicles, G. Strong, Dublin.
22,382. Tobacco Pipes, F. O. Ferguson, Ilfracombe.
22,383. Bookmarks, J. Scott, Manchester.
22,384. Construction of Knitted Gloves, W. Simmonite, Sheffield.
22,385. Flushing Cisterns, T. and W. C. M. Curtis, Dublin.
22,386. Cigarette, F. A. Ware, Cardiff.
22,387. Watch and other Protectors, W. Light, Birmingham.
22,388. Wire Fabrics, W. Waterhouse and T. W. Blantern, Birmingham.
22,389. Joint Rings for Pipe Joints, J. Kirkman, Chorley.
22,390. Machine for Soaking Bottles, J. G. Binnington, Hull.
22,391. Transmitting Orders on Board Ship, W. Chadburn, Liverpool.
22,392. Toy Engines, E. W. Banner, Southport.
22,393. Angler Combination Outfit, H. P. Turner, London.
22,394. Electric Liquid Level Indicator, W. Blenheim, Egham.
22,395. Tea and Dinner Trays, H. T. Simpson, London.
22,396. Brake for Pneumatic Tires, T. Mabbutt, Birmingham.
22,397. Fastening, E. H. Griffiths, Birmingham.
22,398. Protecting Boots and Shoes, E. Carr, Leicester.
22,399. Combustion of Hydrocarbons, F. G. Treharne, Llanishen.
22,400. Hat Blocks, J. Vaughan, London.
22,401. Measuring Textile Fabrics, W. H. Hacking, Manchester.
22,402. Spinning Machinery, W. G. H. Peltzer-Teacher, Manchester.
22,403. Steam Engines, J. Weir and J. G. Latta, Glasgow.
22,404. Self-acting Mules, S. and J. Whitaker, Burnley.
22,405. Tobacco Pipe, C. Makin, Halifax.
22,406. Transmitting Motion, S. Hey.—(*The Bouve, Crawford, and Co. Corporation, United States.*)
22,407. Wheels for Pneumatic Tires, C. E. Bell, F. W. Killingbeck and H. L. Parkinson, Manchester.

22,514. Metallic Alloy for Cutlery, A. J. Hobson, Manchester.
22,515. Detachable Nest Boxes, H. J. F. Rose, Eaton Bray.
22,516. Table, E. Porter, Whitstable.
22,517. Commutator Brushes for Dynamos, W. Begg, Glasgow.
22,518. Spinning Fibrous Substances, W. S. Bancroft, Halifax.
22,519. Grindstone Apparatus, H. A. Mitchell, G. A. Garfitt, and C. Garfitt, Barnsley.
22,520. Combination Walking-stick, E. Brauen, Manchester.
22,521. Gas-lighters, A. Orling, Manchester.
22,522. Lamp Stoves for Cooking, H. V. Rippingille, Birmingham.
22,523. Gear for Transmitting Power, H. B. Trotter, London.
22,524. Apparatus for Drying Clay, J. H. Bowden, London.

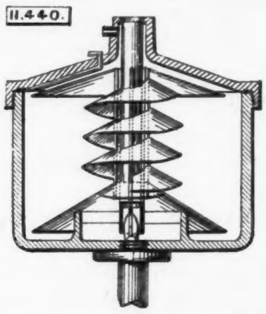
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**11,440.** Centrifugal Cream-separator, *A. Malmros, Stockholm, Sweden.—Filed February* 3rd, 1894.

*Claim.*—In a centrifugal separator, the combination with a revoluble drum, of a feed tube provided at its lower end with a discharge opening, a series of ribs on said tube, a screw-worm supported by said ribs and having a diameter less than that of the interior of the drum, the inner edge of the worm being somewhat removed from the tube whereby vertical passages are formed, a vertical extension of the drum formed upon the bottom of the same, a hood carried by the ribs and arranged above the upper edge of said extension, and a second hood also carried by the ribs and arranged above the upper end of the worm, the drum being provided with discharge openings for the skim-milk and the cream, arranged as described.

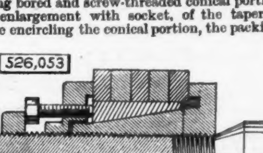
11.440.



**526,053.** Cup-head or Piston-packing, *J. F. Pruden, Oakdale Station, Pa.—Filed March* 15th, 1894.

*Claim.*—The combination with the body portion having bored and screw-threaded conical portion, boss and enlargement with socket, of the tapered split sleeve encircling the conical portion, the packing rings around the sleeve, the cap-piece with threaded extension, and socket, the threaded piston rod, the adjusting screws passed through the cap-piece and bearing upon the sleeve, and the nut on the end of the piston rod and bearing upon the ends of said screws, all substantially as specified.

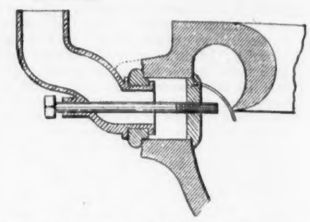
526,053



**526,089.** Coupling for Water-closets, *J. H. Savill, Philadelphia, Pa.—Filed May 7th*, 1894.

*Claim.*—(1) The herein described coupling, comprising a nut or bearing having a spring adapted to engage the flushing rim of a bowl or hopper so as to hold the nut or bearing in position in the bowl, or hopper, a pipe section and connection between the pipe section and the nut or bearing, substantially as specified. (2) The herein described coupling comprising a nut or bearing having a spring adapted to engage the flushing rim of a bowl or hopper, so as to hold the nut or bearing in position in the bowl or hopper, a pipe section, a cushion carried by the pipe section and adapted to bear against the bowl or hopper, and a threaded bolt connecting the pipe section and the nut or bearing, substantially as specified.

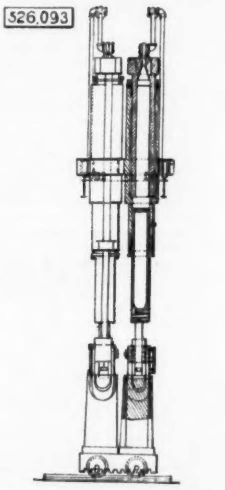
526,089



**526,093.** Ingot Extractor, *H. Aiken, Pittsburg, Pa.—Filed February 17th*, 1894.

*Claim.*—(1) In an ingot-extracting apparatus, a cylinder having two oppositely projecting plungers, one for lifting the mould, and the other for holding down the ingot, and a common water inlet between said plungers, substantially as described. (2) In ingot-extracting apparatus, the combination of a mould-lifting plunger and a down-holding plunger, both being single acting, the down-holding plunger being of less area than the lifting plunger, said down-holding portion having a portion situate in the path of motion of a portion of the lifting plunger, whereby it is engaged during the rise of the latter and is lifted thereby, substantially as described.

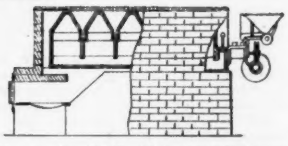
526,093



**526,116.** Process of Making Nitric Acid, *M. Prentice, Stowmarket, England.—Filed October 10th*, 1893.

*Claim.*—The described continuous process for the production of nitric acid, consisting in mixing nitrate of soda and sulphuric acid, dissolving by heat the former in the latter, passing the liquid successively through a series of compartments, subjecting the same in the last to a higher temperature than in the ones preceding, and collecting separately and condensing the vapours produced in the different compartments, as set forth.

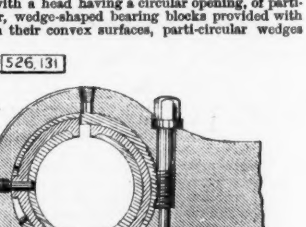
526,116



**526,131.** Adjustable Bearing for Journals, *L. Hollingworth, Chicago, Ill.—Filed May 2nd*, 1893.

*Claim.*—(1) The combination, with head provided with a circular aperture, of parti-circular, wedged-shaped bearing blocks, parti-circular wedges interposed between the walls of the aperture and the outer surface of the bearing blocks, and means for securing relative adjustment between the wedges and bearing blocks, substantially as described. (2) The combination, with a head having a circular opening, of parti-circular, wedge-shaped bearing blocks provided with lugs on their convex surfaces, parti-circular wedges provided with slots for said lugs and interposed between the bearing blocks and the walls of the opening, radial pins entering the lugs and also entering the head and means for adjusting the wedges. (3) The combination, with a head having a circular opening, of parti-circular, wedge-shaped bearing blocks, parti-circular wedges interposed between the bearing blocks and the walls of the opening, a rack on one of said wedges and a worm mounted in the head and engaged with said rack, whereby the bearing blocks and wedges may be adjusted relatively to each other.

526,131



Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided for our breakfast and supper a delicately flavoured beverage which may save us many heavy doctors' bills."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, by Grocers, labelled, "James Epps and Co, Homœopathic Chemists, London.'

## SOUTH WALES RAILWAY AND DOCK BILLS.

South Wales will present a large batch of Railway and Dock Bills at Westminster in the coming session, and if they are not all as important as those of last year, two at least possess a highly contentious character. These are the Barry and Bute proposals, one relating to a new railway, and the other authorising alterations which involve large financial questions in the arrangements between the Bute Company and the railways delivering cargo at Cardiff Docks. The project of the Barry Company consists of six short lines, which together would carry the Barry Railway in a north-easterly direction across Glamorganshire, and over the Monmouthshire border; giving it access to large collieries and an undeveloped coalfield at present served by the Taff Vale and Rhymney Railway; and ending in a junction with the London and North-Western and Midland systems, whereby it would gain direct communication with the North, obtain enormously increased facilities for attracting traffic to Barry Docks, and make Barry itself a more valuable distributing centre. Under the name of the East Glamorganshire Railway the proposal was submitted to the Parliamentary Committee last session as an independent line with a separate directorate; but it was an open secret that the Barry directors were its authors and promoters. It was stubbornly opposed, and after a severe contest was defeated. It is the same scheme, with but slight modifications, that is now revived, and this time it is brought forward as a Barry Bill, and as a step to the natural expansion of the Barry Railway, though to be worked as a separate undertaking. Power is sought to make agreements with the London and North-Western, the Midland, the Great Western, the Rhymney, the Brecon and Merthyr, and the Cambrian companies "with respect to the construction, working, use, management, and maintenance, by any or either of the contracting companies, of the intended railways or any part or parts thereof; the supply of rolling or working stock and machinery, and of officers and servants for the purposes of the traffic of such railways," &c. The London and North-Western Company is supposed to regard the proposed line with sympathetic interest, and it is believed that the Midland is disposed to welcome every means of strengthening its position in the Bristol Channel ports. But as the Barry extension must necessarily tap a large and productive area hitherto reserved to the Taff Vale and Rhymney companies, the Bill will be as stoutly contested as before. As traffic diverted from these lines to the Barry Railway would also be diverted from Cardiff Docks, the Bute Docks Company and other representatives of Cardiff interests are expected to reinforce the opposition. The Barry Company is to work the Vale of Glamorgan Railway, now in course of construction, which extends westward from Barry Docks, through a fertile agricultural district, to the borders of a promising coalfield, as yet only partially developed. In a Vale of Glamorgan Bill, the Barry Company proposes to make deviations in the authorised lines, to extend the period for the compulsory purchase of lands, to acquire additional lands in Penmark and Porthkerry, and to secure the use of the approach roads to the Bridgend station of the Great Western Railway.

Section 23 of the Barry Act of 1888 has been the subject of much costly litigation between the Taff Vale and Barry companies. The dispute arose on the rates charged by the Taff Vale for carrying coal from the collieries on its line to the points of junction with the Barry Railway. The Act limits the toll to the lowest sum the Taff Vale charges anywhere for the "like traffic." The Taff construed this to mean that it might charge Barry on the basis of its rate to the Bute Docks; whereas Barry contended that the lowest sum for the "like traffic" should be based on the rates to Penarth Dock, a greater distance by three miles. The Court of Appeal decided in favour of Barry, and the importance of the judgment will be seen when it is stated that the difference affects three and a-half million tons per annum. But Section 23 covers more than the point as to the lowest rate. It provided that if the Taff Vale at any time refused facilities in collecting Barry traffic at the collieries and carrying it to the Barry Junctions at Havod and Treforest, the Barry Company would be entitled to exercise running powers over the Taff and fetch its traffic for itself. Moreover, the Taff Vale has a branch line running through Penarth to Cadoxton-Barry, originally designed for mineral as well as passenger traffic. Section 23 requires the Taff Vale to abstain from using the Cadoxton branch for mineral traffic; or otherwise the Barry would claim the right of running powers over the Taff Railway above the Havod and Treforest Junctions. This explanation of a complicated situation was necessary to an intelligible statement of the new Bill of the Taff Vale Company. Its main purpose is to amend or alter the agreements embodied in section 23 of the Barry Act of 1888 and a confirmatory section in the Barry Act of this year. The financial issue fought in the Court of Appeal is likely to be carried to the House of Lords; but on the other questions the Taff Vale will ask Parliament to undo what Parliament did six years ago. The Barry Company meanwhile is so little disposed to find fault with Section 23, that it proposes to include it in the Glamorganshire Railway Bill, so as to secure the collection of traffic on the railways specified, and its transfer to Barry over the proposed new line. The other powers sought in the Taff Vale Bill are unimportant, except the proposal for an embankment at Penarth Dock in order to reclaim a portion of the foreshore near the dock entrance, which, so peculiarly are the dock and basin placed, is the only available land for extension of the works.

The Bute Dock Bill concerns itself largely with questions of internal arrangements; but they are arrangements which touch so many interests, financial and otherwise, that the contest promises to be unusually keen and exciting. When the new Bute Dock was before the Committee last session the promoters asked to be relieved of the duty of sorting and carrying to the ships' side traffic which was brought to the dock by the local railways. The railway companies, as things stood, were under obligations to carry traffic gratuitously over the Bute sidings to the staithes or tips, and a similar obligation was placed upon the Taff Vale, Rhymney, and Great Western in connection with the new dock then authorised. Now the Bute Company seeks to repeal the sections of Acts enabling the railway companies to use the Bute line and sidings, with a view to obtaining payment or some other consideration in lieu of rent for the sidings and lines in question. No sooner, however, had the Parliamentary notice been published than a counterblast appeared under the joint names of the Great Western, London and North-Western, Taff Vale, and Rhymney Railways. They gave notice of an application to Parliament for a "Bute Docks Amendment Act" to repeal the clauses or covenants requiring them "to convey traffic of any description over any railways or sidings of the Bute Docks Company, and to relieve the said railway companies, or some of them, from any obligation to convey such traffic or to provide accommodation or render services in connection therewith, except upon terms to be agreed upon between the said companies respectively, and the Bute Docks Company, or to be prescribed or determined by or under the provisions of the intended Act." They ask also to have conferred upon them "all such powers of running over and using the said railways and sidings, and of demanding and reserving tolls, rates, and charges, and to make such other provision with reference thereto as may be found necessary or expedient, and as may be prescribed or provided for by the intended Act." Thus the Bute Dock Company is directly challenged by a combination of railway companies which contends, as indeed the Taff Vale and Rhymney contended last session, that the services imposed upon them by Bute Dock Acts and subsidiary covenants are so onerous and burdensome that they are compelled to ask Parliament for relief.

The Bute Docks Company incidentally proposes to make an easterly extension of the intended sea wall south of the site of the new dock, to reclaim the foreshore thus embanked, and to purchase by compulsion any lands or works required for the purpose of the undertaking. More time is asked for the construction of the sea walls and embankments already authorised. Lord Bute seeks authority to extend his lease to the company to 250 years, or any other period which may be defined. More important in some respects is the application for power to create further capital, and consolidate or convert the existing stock. It is understood that one of the reasons inclining Lord Bute so favourably to receive the overtures of the promoters of the Harbour Trust was his desire to relieve himself of some of the burden of his vast estate. At present the public holding in the company's property, which Mr. Hedley has valued at £4,700,000, is the 4 per cent. debenture stock, of which £800,000 has been issued. The belief is that if the capital is increased, a block of similar debentures will be offered to the public, probably to an equal amount, which would cover the estimated cost of constructing and equipping the new dock. In that case the Bute Dock Company would be following the example of Barry, which is building its dock extension on £4 per cent. Preference stock, while its capital is earning 10 per cent. on the other parts of the property.

Among other railway Bills, the Rhymney Company proposes to construct a new railway in the parishes of Gelligaer and Llanvabon, to acquire more land near Cardiff Station, and to divide the ordinary stock into preferred and deferred, the former to bear 4 per cent. The Rhondda and Swansea Bay asks for powers to construct short railways at Swansea, Neath, and Briton Ferry, and to compel its old antagonist, the Great Western, to complete and fit with signals certain junctions of that company's line with the railways and sidings of the Swansea Harbour Trust, over which the Rhondda Company has obtained running powers for passenger traffic. The Great Western Railway proposes to construct a new line from the bridge over the Rumney river, a few miles east of Cardiff, which will diverge into two branches running on either side of the Roath Dock, while the main line is to be widened for a distance of eight miles between Cardiff and Newport, in order to facilitate the transport of Monmouthshire coal to Cardiff Docks. Further westward the Great Western Company intends building a new station at Carmarthen and abolishing Carmarthen Junction, all main line trains running through the town. The North Pembrokeshire and Fishguard Railway seeks power to extend its line to Carmarthen, and efforts are being locally made to induce the companies concerned to agree to construct a central station at Carmarthen for the joint use of the Great Western, the London and North-Western, and the North Pembrokeshire.

## THE MANCHESTER THIRLMERE WATER-WORKS.

### No. III.

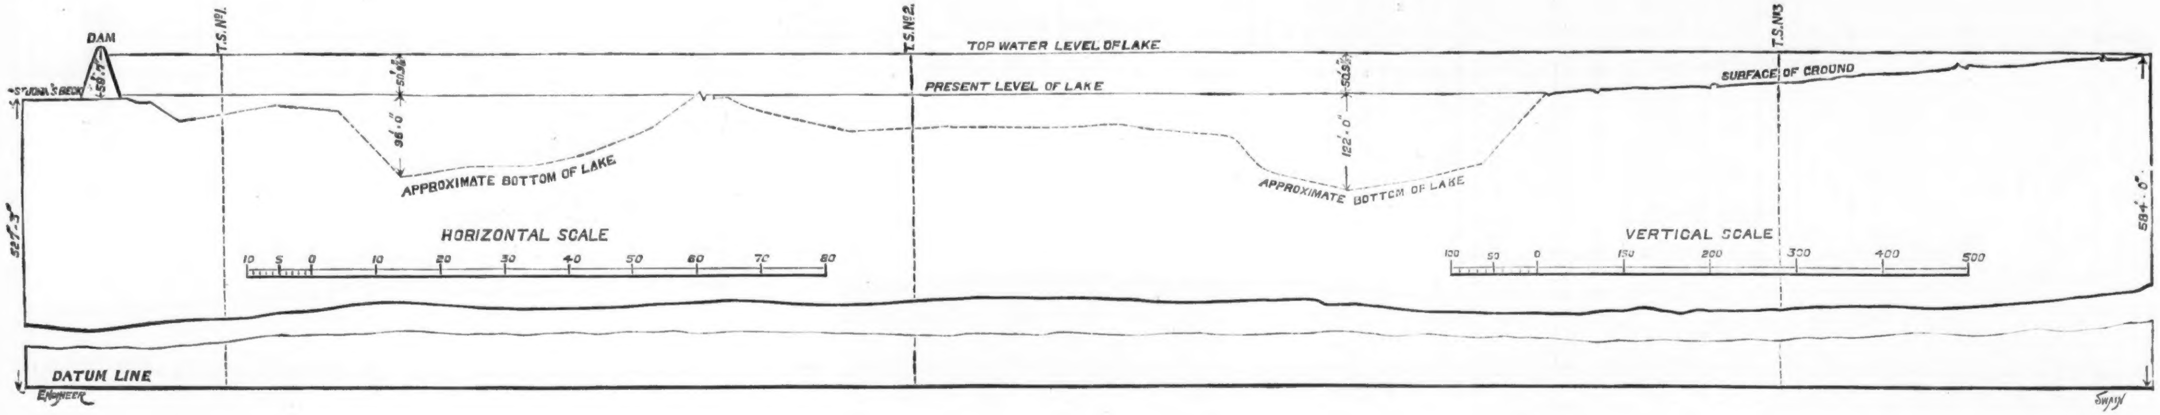
Of the £3,425,000 authorised to be raised for the construction of the works at Thirlmere and the conveyance of water to Manchester, between £2,500,000 and £3,000,000 has been spent in obtaining the first instalment of 10,000,000 gallons a day.

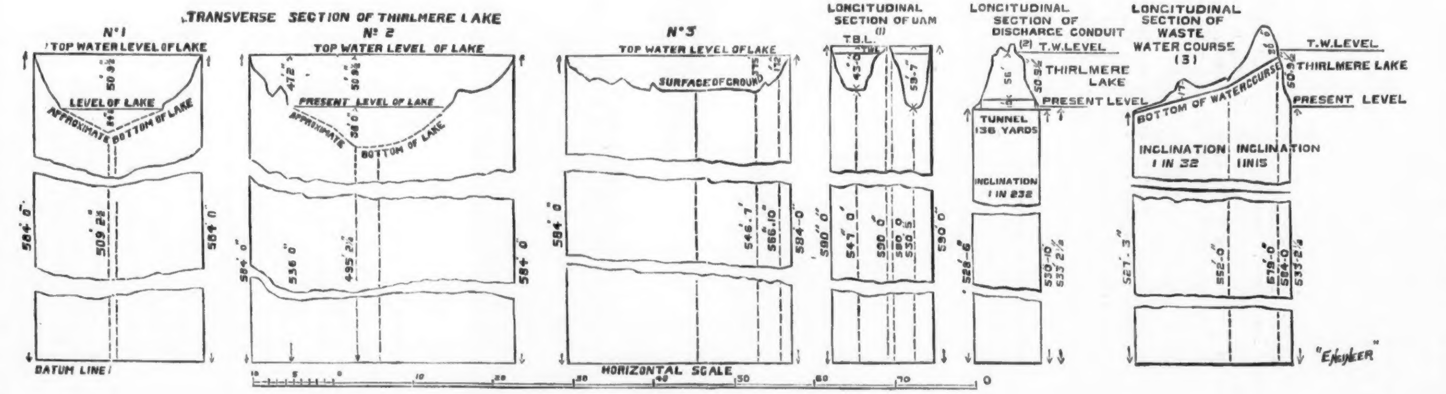
MANCHESTER WATER SUPPLY WORKS—THIRLMERE FROM THE NORTH

Although the acquisition of much of the land before the Act was obtained had simplified matters, still there were many difficulties to be overcome before Manchester was in possession of the authority necessary to enable the work to be carried out. Many costly arbitrations had to be undertaken. What we believe will prove to be the last one is now before Mr. Oakley as umpire, who has to decide on the claim made by the trustees of Lord Lonsdale for payment on account of the stone excavated in making tunnels through the land of which he is Lord of the Manor. This stone was used by the Corporation for making concrete, but their contention is that as the district abounds in this particular stone, it is of no more intrinsic value than an abundance of marl or sand would be in any other place. The most peculiar arbitration was that undertaken to obtain possession of the Countess of Ossalinsky's property, which consisted of about 850 acres. The rental from this was a little over £500 a year, and the Corporation valued it at from £20,000 to £25 000—thus, we should have thought, taking a very liberal view of the value, present and prospective, including a handsome "solatium" for compulsory sale. The values given by those who acted for the Countess ranged from £70,000 to £100,000, extra value being included in consequence, as it was stated, of the land being adapted to waterworks purposes. The award was received with astonishment, amounting as it did to nearly £70,000, and led to an alteration in the law by which the appointment of umpires, when corporations and parties with whom they are dealing cannot agree, has been put upon the same footing as in the case of railway companies under the Land Clauses Act, and the appointment of the umpire is now removed from the authorities of the district and vested in the Board of Trade. A decision was also obtained from the Courts laying down as law that arbitrators are not to value land with reference to the particular purpose for which it is required, especially when Parliament had given powers for the acquisition of the property compulsorily.

The aqueduct which conveys the water from Thirlmere to Manchester is $95\frac{3}{4}$ miles long, and is constructed as follows:—45 miles of cast iron pipes; 37 miles of cut and cover; and $13\frac{3}{4}$ miles of tunnel. We give, p. 492, longitudinal sections of upwards of 27 miles, comprising the most interesting portions of the aqueduct. Commencing at the lake we show 11 miles, including the longest tunnel, which passes under Dunmail Raise, and is 5186 yards long, the greatest depth below the surface being 265ft. It also includes the tunnel under Nab's Scar, which towers above the aqueduct to a height of 660ft.; the tunnel under Skellgill Wood and the Syphon crossing the valley down which flows the Troutbeck—names all of which are familiar to those who have visited the Lake District. On the south side of the Troutbeck Valley there is another tunnel under Moor-How 3040 yards long. There are other tunnels in this district amounting to upwards of 8 miles in the first 14 miles of aqueduct. Several of these tunnels were not driven straight. The long

## THE MANCHESTER THIRLMERE WATER SUPPLY WORKS—SECTIONS OF THIRLMERE





one through Dunmail Raise had two angles, and, therefore required very careful setting out; the junctions, however, were successfully accomplished. Troutbeck was to have been passed in a syphon, but the impetuous stream resented the indignity, and demanded as much consideration as the Lune or the Ribble. Its indignation was shown by repeatedly washing out the pipes laid under its bed, and in the end the engineer had to submit and build a bridge to carry the aqueduct over the Beck.

At 18½ miles we reach the first long length of syphon extending from 18½ miles to 21¾ miles. This is necessary to carry the water across the river Sprint and several other streams, as well as under the London and North-Western Railway Company's main line. The aqueduct is continued by works as above mentioned across country.

We have illustrated two other lengths, viz., the crossing of the river Lune by a syphon extending from 40 miles to 42¾ miles. The level of the aqueduct at this point is 460ft. 10in. above datum, and falls to 42ft.—a drop of 428ft. 10in. This is the greatest drop on the whole line from Thirlmere to Manchester. The inclination through these pipes is 22·6in. per mile. The inclination given through the tunnels and culverts is uniformly 20in. per mile. The pipes are carried over the river Lune by a bridge of three spans at a height of 20ft. above ordinary water level. The rivers Wye and Calder are crossed by syphons. The Ribble is crossed on a bridge. The syphon across the valley extends from 60 m. 4 f. 7 ch. to 69 m. 7 f. 8 ch.—a length of nearly 9½ miles, the fall being 22·8in. per mile. A section of this is given.

The dimensions of the aqueduct through the tunnels and culverts which were constructed in open cutting are 7ft. 1in. wide by 7ft. 9in. high. Through the larger tunnels the height is reduced to 7ft., the width, where side walls were not considered necessary, being increased from 7ft. 1in. to 8ft. 6in.

The floors throughout are of concrete, the side walls of brick or of concrete, and the arches are in some lengths semicircular, in others segments of circles are employed, a rise of 2ft. 6in. being usually given to the latter. For the 13 miles nearest Manchester the aqueduct passes through a colliery district, and is formed of pipes 36in. in diameter, the inclination having been made quicker along this portion. The fall throughout the entire aqueduct is 178ft. from the ordinary level of Lake Thirlmere to the top water level of the service reservoir at Prestwich, a suburb of Manchester on its northern side. The normal fall in the wide aqueduct is 20in. per mile, and through the various lengths of pipes 24in. per mile.

The pipes are of cast iron, 40in. diameter for the greater length, and varying in thickness from 1in. where under slight pressure, to 1⅝in. at the Ribble crossing, where there is a pressure due to upwards of 400ft.; while at the Lune crossing the pressure is due to about 425ft. of head, and the thickness of pipe increased to 1¾in., which is the greatest thickness used. For a short length in the Lake District the pipes have been laid 48in. in diameter, to convey 14,000,000 gallons per diem, so as to avoid disturbing the surface so frequently as elsewhere, three lines of these pipes being sufficient to convey the 50,000 gallons per diem. The ordinary length of pipes is 12ft. Where laid under streams, they are bedded in concrete, and also at the foot of steep slopes. Where the aqueduct crosses the Leeds and Liverpool Canal it is bedded in concrete for the whole width of the canal. Wherever the pipes are above ground-level they are carried on piers and covered by an earth embankment.

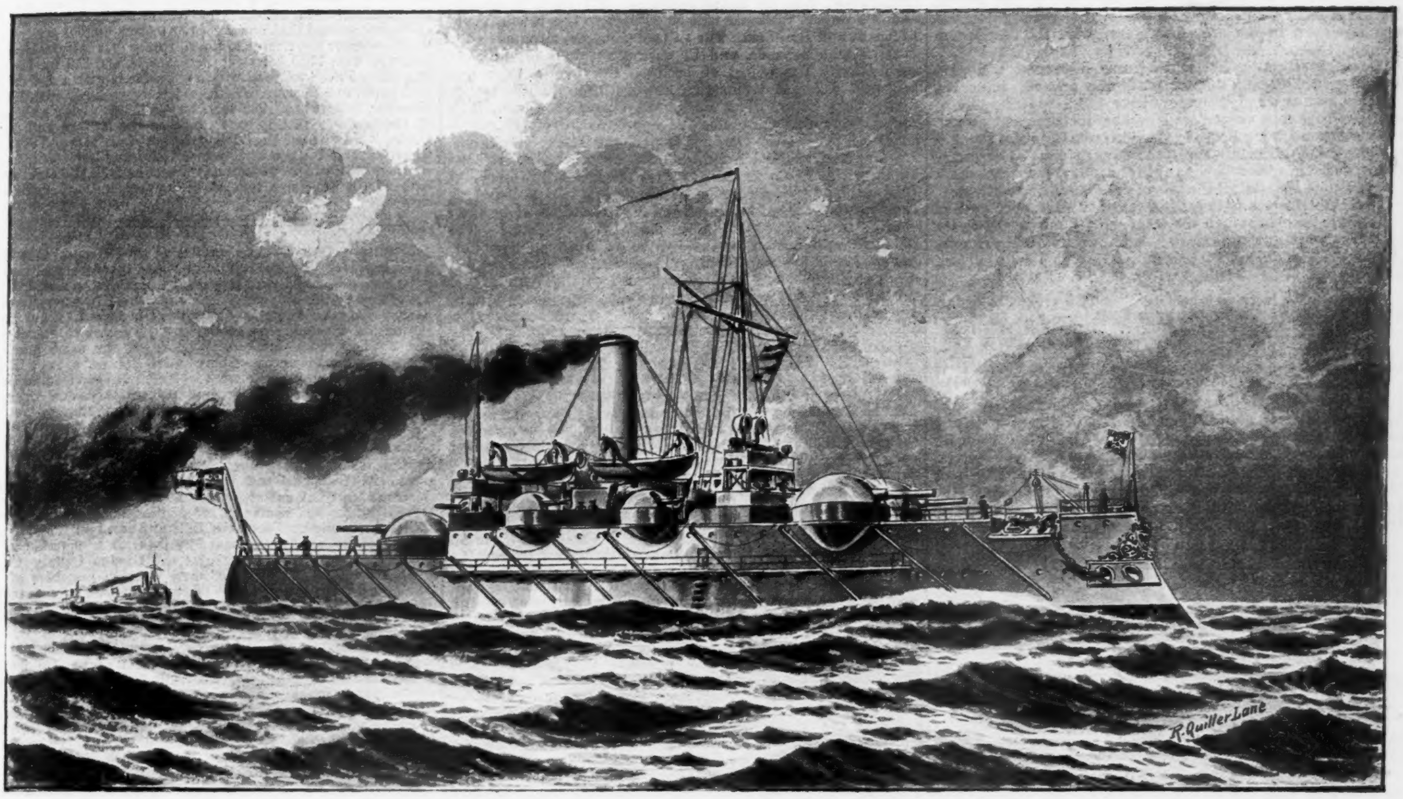
We give an illustration of Thirlmere taken from the north end of the lake near the foot of Raven's Crag. The pass of Dunmail Raise is seen at the extreme south, and the lofty range of hills culminating in Helvellyn on the east. By comparing this with the enlarged plan of the lake published in our issue of the 2nd of November last, the alterations that will be made in the appearance by raising the water 50ft. can be approximately gauged. The farmhouse at Armboth on the west side will be at the edge of the water, and the original coach road from Keswick to Windermere on the east side will be submerged. To provide for the loss of this road, a new road has been made, not only on the east but also on the west side, so that there is now a wide and excellent drive on both sides of the lake. The cost of making these roads was borne by the Corporation of Manchester, and added considerably to the expense incurred by them.

*To be continued.*)

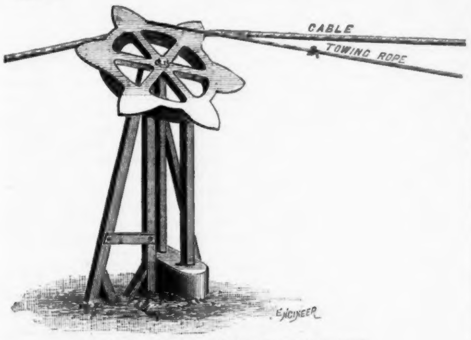
## CABLE HAULAGE ON CANALS.

The system of haulage by means of cables worked by machinery has long been considered in France as one of the most promising expedients for securing the greatest economy and efficiency in the towing of boats on canals. The simplicity of the idea naturally appealed to inventors, who seemed to think that there was little question as to the possibility of its being carried out successfully. A great deal of attention was consequently given to this principle of canal traction, and several experimental installations were carried out with a view of testing some of the systems then introduced. In 1884, M. Rigoni laid down an installation on the St. Martin Canal, and it was then seen that the idea was not so simple as it appeared. The cable worked very irregularly, and was constantly being pulled out of the pulleys, so that it was speedily abandoned. The same fate awaited the installation laid down by M. Oriolle on the St. Quentin Canal. The difficulty of preventing the escape of the cable from the pulleys offered plenty of scope for the ingenuity of engineers, and some of the most likely contrivances failed to act properly when put into practice. As events have since proved, this drawback would have been easily remedied if the cable could be made to run in a perfectly straight line, but in most installations there is scarcely a hundred yards of cable in which the direction has not to be changed by pulleys. The inequalities in the ground, the locks, the tunnels, and the curves in the canal, necessitate a great many pulleys of various shapes and sizes, and these at first offered a serious impediment to the passage of the tow rope attached to the cable. MM. Rigoni and Oriolle employed in their installations ordinary pulleys with smooth grooves, from which the cable was pulled away by the oblique strain of the boat. When at length this was overcome a still greater difficulty presented itself in the awkwardness of turning corners by means of the cable. In the horizontal pulleys changing the direction of the cable away from the canal, and in the vertical pulleys carrying the cable either over or under, the towing rope can pass easily without obstruction; but in many cases the cable takes an inward direction, with the result that it has to pass around the outer edge of the pulley. It was evident, therefore, that the horizontal pulley carrying the cable away from the canal would have to be suppressed, and some other system devised whereby the towing rope would continue to follow the cable without interruption. This difficulty has been overcome by M. Maurice Levy, Inspector-general of the Ponts et Chausées, who has just prepared a voluminous report upon his system. M. Levy induced the Government to authorise a trial of his system in 1888, when he laid down an installation upon the Marne, the Saint Maur and Saint Maurice Canals, a distance of 5200 metres. This installation presented nearly all the difficulties that could be met with in such an undertaking, so that if successful there could be no question as to its efficiency for the general purposes of canal traction. The installation was laid down in four sections—one starting about 150 metres above the Joinville Bridge and finishing at the Saint Maur Tunnel; another passing underneath the tunnel; a third working between the tunnel and the Gravelle Lock; and a fourth between the Gravelle Lock and the Charenton Lock. The cost of the whole installation was 150,000f., or 25,000f. per kilom. At first, operations were restricted to the line from the Saint Maur Tunnel to the Gravelle Lock, and this work was completed in four months. The engineering and Government officials were so far satisfied with this line that permission was given to complete it over the three other sections. This extension was a particularly awkward undertaking from the fact that it had to serve the port of Charenton, which has a length of 250 metres, had to pass underneath a tunnel 600 metres in length, had to go through the Gravelle lock, to which entrance is made extremely difficult on account of a bridge and a sharp curve, and had to cross a branch of the canal of St. Maur by a

# THE SIEGFRIED, GERMAN IMPERIAL NAVY



single span of 121 metres, to say nothing of the numerous curves that had to be met along the route. The installation comprises an endless cable that starts from the Gravelle lock, and after following on one side of the canal, crosses at Charenton and returns on the other side. A second endless cable makes a similar circuit from the Gravelle lock to the river Marne by way of the Joinville tunnel. Special attention has been given to facilitating the attachment of the towing rope to the cable, and this is effected by means of short lengths of rope that hang from the cable at regular intervals, and provided with an ingenious clutch. The boatman can attach his tow rope to the clutch in a few seconds without leaving the boat, and by merely pulling a lever the boat is loosened in a moment. The principal feature in this system is the ingenious method that has been adopted to prevent the cable slipping from the pulleys. This is done by constructing the pulleys, where necessary, with a serrated flange, so that the towing rope will enter one of the notches, and will leave it at the other side when the pulley has made a partial revolution. While plenty of freedom is thus left for the towing rope to pass over the pulley, the flange will prevent the cable from being pulled away. This principle has been developed to a singular extent at the curves, where the cable has to pass outside the support.



CANAL ROPE TOWING STANDARD

The horizontal pulleys which at first gave so much difficulty have been replaced by oblique pulleys. In this new system the upper face is star-shaped, the flange bearing four or six prolongations that are made almost semi-circular in form, so as to facilitate the entrance and release of the cable. These oblique pulleys have a diameter inside the groove of two metres. Of course, in the position in which the pulley is placed the cable exerts a constant strain upon the flange, but the star-like projections are made sufficiently large to preclude the possibility of the cable escaping. The motive power for this installation is supplied by a horizontal engine placed at the Gravelle Lock. On each side of the engine-house are three pulleys for operating the two circuits, the one working as far as the river Marne, and the other to Charenton. Two of the pulleys are built in solid masonry, and the larger one receives its power direct from the engine. The second pulley serves merely to keep the cable in its place upon the driving pulley. A third pulley works upon a running frame, and acts as a tension-wheel for the cable. In such an extensive installation the cable has naturally a tendency to be always slackening, and when this takes place the sliding pulley, around which the cable is wound, is drawn away from the driving pulley so that the cable may be tightened. The rate of speed imparted to the cable is one metre per second, but it is stated that this is too fast for the boatmen, who have asked that the speed should be reduced. This system of M. Maurice has put beyond question the possibility of hauling boats upon canals by means of mechanical cable traction, but this possibility will avail nothing if it is not found to be at the same time efficient and economical. So far, it cannot be said that M. Levy's system has met with the success that was at one time looked upon as being assured.

It is the general opinion of engineers that nothing could be more satisfactory if the cable could be worked in a perfectly straight line, but where the cable has to be turned in different directions by pulleys of all shapes and sizes, and sometimes placed two and three together, the friction must necessarily result in an enormous waste of power, to say nothing of the wear and tear of the cable. The installation upon the Saint Maur and Saint Maurice Canals has never passed much beyond the experimental stage, and the work which it has done has certainly not justified the cost of the installation. It is believed that the system can only be economical upon canals with a heavy traffic. With a traffic of a million tons a year the cable traction could be employed with great advantage, and from this point the economy would increase in proportion to the augmentation of traffic, until an economy of 50 per cent. could be effected upon the present cost of working, with a traffic of from three to four million tons. As there are many canals in the north of France fulfilling these conditions, the system is at the present moment being experimented with in view of its further extension, and it is likely that an installation will be laid down shortly on the canals in the Loire. The Government of Holland is also carrying out experiments upon the Aisne Canal adjoining the Marne, where the first section has already been laid down in the Billy Tunnel. Similar experiments have been carried out for some time past by the German Government upon the canal from the Oder to the Spree, and the results are being looked forward to with great interest. Though the system has not so far been an unqualified success from an economical point of view, it is the opinion of engineers in France that it has a great future before it, and that it will be used extensively upon canals carrying a heavy traffic.

## THE SIEGFRIED, GERMAN IMPERIAL NAVY.

We illustrate above the Siegfried, a recent addition to the German Imperial Navy, the first—completed—of eight of a type, of which, unfortunately, we have no counterpart in our Royal Navy; although as long ago as March, 1893, Lord Charles Beresford, in his "Programme for proposed increase of British Fleet," strongly recommended such a class of ship to watch the torpedo stations of an enemy, and destroy his boats, &c.

The Siegfried is like the other vessels of her class, 240ft. long, and has a displacement of something like 3500 tons. She is provided with a belt of steel armour at the water line the entire length of the ship the belt being 7ft. 6in. deep and 9·4in. thick. Her armament consists of three 9·4in. Krupp guns, in barbettes, two forward and one aft, the barbettes being protected by 8in. steel armour; and six 3·4in. quick-firing guns, by the same maker. She is also provided with four torpedo tubes, two being submerged.

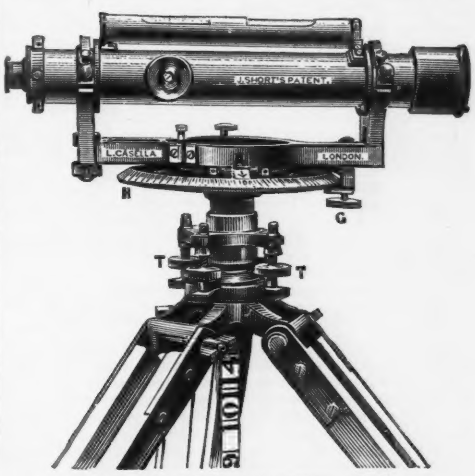
Her speed is between fifteen and sixteen knots, and she has a complete electric light installation, besides being warmed throughout by hot-water pipes.

The names of the other ships are Odin, Beowulf, Frittijof, Hagen, Heindal, Hildebrand, and one "T," still unlaunched, and building at Kiel.

## THE GRADIENT TELEMETER LEVEL.

We have lately had the opportunity of examining a new form of surveying instrument invented by Mr. J. Short, which promises to be of great service by economising time and labour in the preparation of detailed surveys for engineering works, without in any way impairing the accuracy of these indispensable but laborious operations, when compared with the methods in current use.

This instrument, which has been named by the inventor the gradient telemeter level, is constructed for the purpose of determining linear distances, gradients, and differences of level by a single observation, without the use of chain or tape, for measurement on the ground. As will be seen from the illustration, it resembles an ordinary dumpy or Y level, with the addition of a divided horizontal plate or limb H, turning upon an axis, which is exterior to that of the cross-bar carrying the Y's of the telescope. This outer axis, however, is not parallel to the inner one, but both have different centres inclined to each other, so that it is only when the instrument is set with the index G clamped to the zero point of the scale on the limb and levelled upon the outer centre, that the line of sight lies in the horizontal plane. If, now, the clamp screw be released and the outer limb moved by hand so as to bring another part of the scale under the index, the visual plane will, by the canting of the axis, be inclined or depressed by an amount corresponding to the obliquity of the two axes in that position, and which is expressed by the reading on the scale in terms of the gradient, although any other system of division may be used if desired. The limiting obliquity of the two axes of course depends upon the construction of the individual instrument; in the one that we have examined it was, we believe, 1 in 12, or about 11 degrees of arc. When used in taking gradients the level reading is taken upon the staff in the ordinary way, the height of the centre of the objective of the telescope above the ground at the station being read upon a tape hung below the tripod stand. The telescope is then unclamped, and the line of sight is lowered—on a falling gradient—until the staff reading is made to correspond with the height of the instrument, when the index will stand at the point of the scale giving the gradient required, apart from any consideration of distance between the points, whether long or short. The method of observation on a rising gradient is similar, except that the telescope must be reversed in the Y's so as to bring the object glass end next to the clamp screw G. The difference, whether rise or fall, is learned by noting the word "rise" or "fall" engraved on the eye-piece end of the stage carrying the Y's.



SHORT'S GRADIENT TELEMETER LEVEL

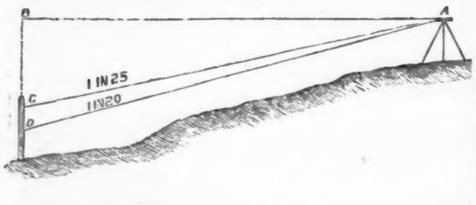
As the level line is only required in the preliminary setting up of the instrument, gradients may be determined by it when the vertical interval between two stations is as much as 90ft. or 100ft., or when the instrument is between two stations, differences up to 200ft. may be determined in a few minutes with an ordinary 14ft. levelling staff, when a pair of readings upon it can be obtained with the telescope at two known degrees of inclination. An example of this class of application is shown in the annexed figure, with the description given by the author.

"Method of getting horizontal linear distances, and also levels up to 90ft. and 100ft. on sloping ground, when the levelling staff is wholly below or above the horizontal line of sight, without moving the staff or the instrument. When the instrument is levelled, and the horizontal line of sight A B is above the top of the 14ft. staff, proceed as follows:—Loosen the clamp and move the telescope until the index reaches gradient 100, and sight the staff; if the line of sight is still above the staff, move the telescope and index farther until the upper part of the staff is visible through the telescope. Suppose the index is then near gradient 28, move it again until it cuts exactly gradient 25, then take the staff reading at that gradient. Suppose this to be 13·86ft.,

Then move the index on to gradient 20 and again read the staff; let this reading be 8·45ft. and take their difference thus .. .. .. .. .. Gradient 25 = 13·86
Gradient 20 = 8 45

Difference between 1 in 25 (4 per cent) and 1 in 20 (5 per cent) = 1 per cent. or 1 in 100 .. .. .. .. .. .. .. .. = 5·41

Eliminate the decimal point, and the horizontal linear distance A B, as in above illustration, is 541ft., without any calculation being necessary for hypothenusal difference or for other reduction. For facilitating this class of work a series of pairs of gradients are engraved on the limb, any pair of which will give by the difference of their readings the horizontal distances in this manner—the choice of gradients being determined by the nature of the ground."



The instrument has been tried by engineers engaged on railways and other public works both in this country and abroad, and has everywhere met with a most favourable reception. Mr. Beckett, of the Manchester Ship Canal; Mr. Cooper, Borough Engineer, of Edinburgh; Mr. Binnie, of the London County Council; and Mr. Weightmann, Consulting Engineer for Railways in Madras, among others, having expressed their sense of its novelty and value. As an example of the class of work done by it the figures contained in the following trial will be of interest:—

*An Abstract from the Report of the Trial of J. Short's Patent Gradient-Telemeter Level by the Royal Engineer Committee, at Chatham, in the Spring of* 1892.

| No. of Station. | Gradients used. | Chained Distance. | Error by Grad. Ter. Level. | | Remarks. |
|---|---|---|---|---|---|
| | | | Minus. | Plus. | |
| | | Feet. | Feet. | Feet. | |
| I. Back | 17 and 34 | 115·50 | 0·75 | | |
| Forward | Level and 25 | 288·42 | | 0·33 | |
| II. Back | Level and 50 | 289·25 | | 0·25 | |
| Forward | Level and 60 | *— | — | — | *This was a bad reading due to smoke obscuring the staff.<br>A. O. Green, Major, R.E. |
| III. Back | Level and 20 | 362·34 | | 0·36 | |
| Forward | 20 and 30 | 278·52 | 0·12 | | |
| IV. Back | 20 and 30 | 435·60 | nil | nil | |
| Forward | Level and 20 | 119·46 | | 0·14 | |
| Distance by Chain .. .. = | | 1839·09 | 0·87 | 1·08 | |
| ,, by Gra. Tel. Level = | | 1839·20 | | 0·87 | |
| Difference .. .. .. .. = | | 21 | | 0·21 feet = 2½in. about. | |

Result.—In the "traverse" or distance measured above with the Gradient-Telemeter Level of over 613 yards, the error or difference compared to the land chain measurement was only about 2½in.; this means that in one mile of ground measured with this instrument the difference would be less than 8in. And distances can be got with all this accuracy across water, or rough and broken ground, where the land chain cannot be used at all. (Signed) A. O. Green, Major R E.

The construction of the instrument has been confided to Mr. L. Casella, of 147, Holborn Bars.

## NEW WATER SCHEMES FOR YORKSHIRE.

The remarkable dry summer of last year seems to have taught Corporations a lesson in respect to their water supplies. No fewer than three separate applications to Parliament for water rights have been made in respect to one of the chief moorland streams by three important Yorkshire boroughs. The Barnsley Corporation, who have capital works on the moors at Ingbirchworth, and an old water supply unused, are promoting a Bill to Parliament to construct a reservoir at Midhope by throwing an embankment across the valley of Hagg Brook, about eleven chains from Hagg Bridge, which crosses the valley, and provides a road from Upper Midhope to Midhope Stones. A number of important tributaries to the Little Don, including Hagg Brook, Edge Clyfe Brook, and Thickwood Brook, are to be impounded. The proposed line of pipes is to pass through the township of Wartley, for the most part the property of Lord Wharncliffe, to a service tank which is proposed to be constructed. Leaving Wartley the line of pipes passes through some part of Tankersley, famous for large ironworks and collieries, belonging to Messrs. Newton, Chambers, and Co.; through some portion of the township of Wartley, Darfield Marshes, and on to Barnsley, terminating near Sheffield-road, in the borough. The Corporation seek for power to extend considerably the limits within which they are authorised to supply water. The proposed route would give a supply to many places where the natural springs have become dry, owing to the working of the coal measures. Mr. J. H. Hawksley is engineer to the scheme, which is estimated to cost £170,000. The Dewsbury and Heckmondwike Water Board, which already have extensive reservoirs and works at Dunford Bridge, on the same moors, have given notice to promote a Bill in Parliament to construct a reservoir on the Porter or Little Don River, which is collected in the first instance in a swampy tract in the neighbourhood of Lady Cross, a flat extent of moorland property belonging to Sir L. Pilkington, of Chevet Hall. The proposed reservoir is to be formed from east to west by an embankment, 203 yards in length, and the entire reservoir will be situate in the townships of Langsett and Bradfield. The two schemes are situated in the same neighbourhoods, and in valleys within a few miles of each other. The object of both schemes is to take and impound different tributaries flowing into the Porter or Little Don River. The Rotheram Corporation are, it is stated, promoting a Bill for the appropriation of the watersheds of the Little Don River and the Hagg, Thickwood, Hardin, and Mickleden Brooks, and all other streams flowing into the Little Don. The fact of three such important Bills being promoted relating to streams and tributaries which supply important works, mills, and manufactories along their course, is certain to lead to powerful opposition. The Sheffield mill owners are said to be up in arms. The Parliamentary expenses attending the Barnsley scheme are put down at £10,000, and in a report issued to the Water Committee it is admitted that considerable opposition may be expected.

## MR. WILLIAM ALLAN ON THE NAVY.

Mr. William Allan, M.P., addressing his constituents at Gateshead on Tuesday night, alluded especially to the Navy, and said he was no alarmist, but Great Britain was the most helpless nation on the face of the earth, because she was the only nation dependent upon other countries for a food supply. No other nation was situated so hardly or so dangerously as the British nation in this respect. Blockade France, America, Germany, or Russia, and those countries could live by themselves. Blockade English ports, and there were not six weeks' provisions with which to feed the people. The lesson to be derived from this was, that we of all nations must command the sea. Our position demanded that we should have such a fleet of well-manned ships that, come what might, we could guarantee to working men and women that they should get their provisions as cheaply as they could to-day. We were building the finest ships in the world, but the black spot was that we had no docks to put them in. The dock accommodation at Devonport and Portsmouth was not sufficient for the purpose of docking damaged vessels, especially the powerful cruisers now building. Round all the other coasts of England and Ireland there were no docks, although there were splendid places on the Irish coast where docks could be built. In the event of a naval battle in the Mediterranean there was not a single dock at Gibraltar for them to go to, and they would have to work their way to Malta, where there were two or three badly-equipped docks, or else steam several days to Devonport, without much chance of reaching either place. We had no docks at the Cape or in the East Indies. If the French ruled Madagascar, he ventured to say that within two or three years they would have there an arsenal and docks, which would check the growth of the British Empire in the south of Africa. How were the ships upon which we spent millions manned in the engine-room? On the Revenge, built at Jarrow, there were eighty-six engines, and these had to be looked after by seventeen mechanics, and the same proportion of engineers was maintained throughout the Navy. There were no reserves of engineers, no reserves of engine-room artificers, and no reserve of stokers. Engineers and engine-room artificers could not be induced to join the Navy. The Navy was in this condition because the Board of Admiralty was antiquated. The First Lord of the Admiralty knew nothing about engines or ships, neither did the Secretary of the Admiralty, who was a country squire. The Civil Lord of the Admiralty was a lawyer and was equally ignorant of the wants of the Navy. He accused both Liberal and Conservative Governments of neglecting their duty in this matter. The Board of Admiralty consisted of seamen not at all in sympathy with science. These men thought only of the fighting element in our fleets and overlooked the vital importance of the engine-room. There should be an equal representation of engineers and captains on the Board. He did not intend that this question should be lost sight of. What he had told them was the truth, and went to show that the neglect of our first line of defence was calculated to leave England helpless.

## MANCHESTER SHIP CANAL.

As we have aways contended, the growth of traffic between the new port of Manchester and the rest of the maritime world must of necessity be slow, and in the outset very difficult.

Still, in spite of the keenest competition and the most bitter opposition, the shipping trade is gradually gravitating towards Cottonopolis direct, and not through Liverpool as heretofore; and the last few weeks have seen quite a forward movement in more than one quarter. Under the guidance of the present traffic manager—Mr. J. K. Bythell—himself an old East India merchant, a contract has been arranged by the Ship Canal Company and the Bombay Native Piece Goods Association, securing all shipments during the next two years "*via* Ship Canal."

In this connection it has been announced that the new steamship Empress—2900 tons—will sail from Salford for Bombay on the 10th January next; and she will be followed by the steamship Castleventry ten days later, thus inaugurating a regular succession of sailings every tenth day, which will be augmented from time to time as required. Another important item in the annals of the city is the securing of direct consignments of raw cotton to be distributed at once from Salford Docks, and not through the agency of the Liverpool Cotton Exchange. Last week the first of these cargoes of this year's American cotton crop reached the Mersey *en route* for Manchester, and quite an exciting scene followed on their arrival in the estuary. The Darlington from Galveston, U.S.A., with 7083 bales, entered the Mersey on the morning tide of the 21st ult., and dropped anchor in the Sloyne. Shortly afterwards, her rival, the Delano, 2968 tons, from New Orleans, with 7000 bales for Manchester, crossed the bar and at once proceeded to enter the canal at Eastham about 9 a.m., although it was then 3½ hours after high water.

The skipper of the Darlington finding himself thus overhauled, weighed anchor and tried to follow the Delano into the canal; but in his excitement and haste, ran on to a sandbank and remained grounded in the river till the next tide. Meanwhile the Delano, after passing the Customs officer at Eastham, left at 10 o'clock the same morning for Manchester assisted by one tug. The Lockmaster at Eastham telephoned at once that the Delano was underway for Latchford—the half-way house of the canal, and head of the tidal portion—that he was just about to pass the s.s. Dalton—Lamport and Holt line—down to the tidal pond on her way out to sea.

In the ordinary course the two vessels would thus pass each other near Runcorn; but, seeing that the Runcorn bend is one of the sharpest in the whole line of work, and that these two vessels were both of large tonnage, it was arranged between the two officials that the outward bound Dalton should lie up at Old Quay above Runcorn and await the passing of the Delano. With these instructions therefore the Dalton steamed away from Latchford Locks, but, safely under way, the pilot and skipper seem to have put their heads together and arranged, that come what might, they would quietly steam down stream and past the Delano "bend or no bend."

After all that has been said, and is still being repeated by those hostile to the canal, as to its being impossible for two vessels to pass each other, it is interesting and instructive to find that these two ships—the Dalton, 315ft. by 34ft. beam, and the Delano, 320ft. by 41ft. beam, not only met, but passed under steam on one of the sharpest curves of the canal, and did so without the least trouble or mishap. This afforded a direct contradiction of the recent remarks of a well-known opponent of the canal.

We understand that one Egyptian cotton crop is coming direct to Manchester also; the s.s. Royal Prince left Alexandria on the 15th ult. with 2910 bales for Manchester, and 843 for Liverpool. The Sailor Prince followed within a few hours with a full cargo for both ports, and the Swedish Prince left a week ago with 1500 odd bales for Salford, and 960 for Liverpool. As giving a slight idea of the business already being done at the Salford and Pomona Docks, it may be mentioned that the list of arrivals and departures which appeared in the local press of one day last week, included eighteen vessels in the canal, and thirteen arrivals and eight sailings, without counting five tugs, three hoppers, and twenty-five cargo barges.

Liverpool Trade.—At a meeting of the Liverpool City Council on Wednesday, Sir W. B. Forwood said the Liverpool trade was not growing as rapidly as they had a right to expect, but it was not caused by the Ship Canal. It was caused by the railway companies, who were strangling the trade of Liverpool. They charged 8s. per ton for conveying goods from Liverpool to Manchester—about thirty miles—while they conveyed the same goods from London to Southampton—ninety miles—for 6s. a ton; that was the reason the grain trade went to Hull. No good would be done until Liverpool took the matter into its own hands and constructed its own line between Liverpool and the Midland towns.

The New London Building Act.—The London Building Act, which has recently been passed, and which comes into operation on the 1st of January next, has a number of provisions with respect to the height and curtilage around buildings, as well as other matters that are of great sanitary importance. The Sanitary Institute has arranged for a discussion to be held at the sessional meeting on December 12th at 8 p.m., on "The Sanitary Aspects of the Act," to be opened by Dr. G. B. Longstaff, chairman of the Building Act Committee of the London County Council, when other members of the County Council, members of local boards and vestries, and those officers who will be concerned in carrying out the provisions of the Act, are expected to take part in the discussion.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on the 3rd inst., Sir James Crichton-Browne presiding. The following lecture arrangements have been announced:—Professor J. A. Fleming, F.R.S., six lectures—adapted to a juvenile auditory—on "The Work of an Electric Current." Professor Charles Stewart, twelve lectures on "The Internal Framework of Plants and Animals." Mr. William Samuel Lilly, four lectures on "The English Humourists of the Nineteenth Century." Mr. L. Fletcher, F.R.S., three lectures on "Meteorites." Dr. S. Rawson Gardiner, three lectures on "Three Periods of Seventeenth Century History: (1) The Monarchy; (2) the Commonwealth; (3) the Restoration." Dr. E. B. Tylor, F.R.S., two lectures on "Animism." Mr. Lewis F. Day, three lectures on "Stained Glass Windows and Painted Glass from the point of view of Art and Craftmanship." Dr. A. C. Mackenzie, three lectures on "Hänsel and Gretel," an opera by E. Humperdinck—with musical illustrations. The Right Hon. Lord Rayleigh, six lectures. The Friday evening meetings will commence on January 18th, when Professor Dewar will deliver a discourse on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air." Succeeding discourses will probably be given by Sir Colin Scott-Moncrieff, Mr. Henry Irving, Dr. G. Sims Woodhead, Mr. Clinton T. Dent, Professor A Schuster, Professor A. W. Rücker, Professor Roberts-Austen, Professor H. E. Armstrong, the Right Hon. Lord Rayleigh, and other gentlemen.

The Conference on Light Railways.—On the invitation of the Board of Trade, the following bodies were represented at the Conference on Light Railways, which took place yesterday. London County Council: Rev. Fleming Williams, Mr. Bruce, Mr. Beachcroft. Association of Chambers of Commerce: Sir Albert Rollit, M.P., Sir Bernhard Samuelson, M.P., Sir Alfred Hickman, M.P., Mr. F. Corbett. Central and Associated Chambers of Agriculture: Mr. Channing, M.P., Mr. Jeffreys, M.P., Mr. R. H. Rew. London Chamber of Commerce: Sir Edward Carbutt, Mr. E. Garcke. Railway Companies Association: Lord Claud Hamilton, Mr. J. C. Bolton, Mr. W. L. Jackson, M.P. Institute of Civil Engineers: Sir Benjamin Baker, Sir Douglas Fox. Association of Municipal Corporations: Mr. Alderman Brownswood, Mr. Harcourt Clare, Mr. G. C. Kent. Association of County Councils: Sir John Hibbert, M.P., Lord Thring, Lord Edmond Fitzmaurice, Mr. Henry Hobhouse, M.P. Scottish Chamber of Agriculture: Mr. Alexander Cross, M.P. Surveyors' Institution: Mr. E. P. Squarey, Mr. C. Oakley. Tramways Institute of Great Britain and Ireland: Mr. Carruthers Wain. Mansion House Association on Railway and Canal Traffic: Sir James Whitehead, Mr. Tomlinson, M.P. Institution of Electrical Engineers: Mr. Alexander Siemens, Major-General Webber. Royal Agricultural Society of England: Earl Cathcart, Mr. W. Frankish, Mr. Ernest Clarke. National Traction-Engine Owners' and Users' Association: Mr. R. W. Eddison. British Dairy Farmers' Association. In addition, certain gentlemen having expert knowledge of the subject matter will attend the Conference, among whom are the following:—Duke of Sutherland, Lord Farrer, Lord Kelvin, Sir Juland Danvers, Sir Alexander Rendel, Mr. W. M. Acworth, and Sir Richard Sankey.

New South Wales Railways and Tramways.—The following is from the report of railway commissioners for the quarter ending September, 1894. It shows some considerable improvements and lessened percentage of expenditure, but there have been also less receipts in its tramways. The report is signed by Mr. G. M. Eddy and others:—

| Railways. | | 1893. | 1894. | Quarter ending Sept 30th, 1893. | Quarter ending Sept. 30th, 1894. |
|---|---|---|---|---|---|
| Miles open | | | | 2,390 | 2,501¼ |
| Revenue | Passenger | £233,626 | £231,011 | £684,916 | £667,892 |
| | Merchandise | £451,290 | £436,881 | | |
| Expenditure | | | | £421,926 | £371,840 |
| Train miles run | | | | 1,800,931 | 1,821,247 |
| Earnings per train mile | | | | 7s. 7¼d. | 7s. 4d. |
| Expenditure per train mile | | | | 4s. 8¼d. | 4s. 1d. |
| Percentage—Expenditure to earnings | | | | 61·60 | 55 67 |
| Number of passengers | | | | 4,747,616 | 4,685,517 |

Although considerable expenditure has been incurred and debited to working expenses, in renewing the permanent way, and other works, the total expenses for the quarter show the satisfactory decrease of £50,086. The percentage of the expenditure shows a decrease of about 6 per cent. from the cost of working for the corresponding period of 1893.

## RAILWAY MATTERS.

The South-Indian Railway are rapidly fitting the whole of their rolling stock with the vacuum brake.

The linking-up of the metre-gauge railways in Northern India and on the Madras-Ennore line is to be commenced at once.

An extra rail has been laid throughout most of the Oregonian Railway system—narrow gauge—thus rendering it available for trains of the usual standard gauge.

There are nearly [illegible] hundred miles of street railway lines within the city boundary of Los Angeles, California, worked principally by cables and electricity, and carrying about 12,000,000 passengers per annum.

Two railways in Turkestan are under consideration. One of these lines, as we have before stated, is from Samarkand to Ardisham, with a branch to Tashkend. Both lines would penetrate a cotton producing country 1500ft. to 2500ft. above the sea in the valleys. The Russians think they might get a large part of their cotton supply thence.

The Portuguese Government have sanctioned a railway in their West Africa possession, Benguela, from Lobito Bay, a little north of Benguela, about 190 miles to Chaconda, in the interior. Another charter has been granted for a line from Mossamedes, a coast town some 180 miles south of Benguela, up the Bero River to the foothills of the Chella plateau.

The new line under construction between Exeter and Chagford will be about twenty-six miles long, and, with one exception—that of a tunnel—presents no engineering difficulties. The estimated cost is £240,000, or about £14,000 per mile. The Great Western Railway has entered into a contract for working the new line, and a connection will be formed with the Exeter Canal.

According to the British Consul at San Francisco, a new transcontinental railway to that place is in contemplation. It is said that the San Francisco and Atlantic will form a junction with the Atlantic and Pacific Railway in either King's or Los Angeles County, California. The contracts for the construction of 300 miles of the line south from San Francisco have been let.

The cable electric railway to a peak of the Tierra Madra Mountains, overlooking Los Angeles, being constructed by the Passadena and Mount Wilson Railway, is completed to Echo Mountain, 3500ft. above the sea. The second section is 3000ft. long, and makes a direct ascent of 1300ft. The third section extending the line to a peak 6700ft. above the sea will now be constructed.

It is stated in the report of the Greek Ministry of Public Works that there are 568 miles of railway in operation in that country, exclusive of 204 miles under construction, and 214 more chartered. Of these 272 miles are of standard gauge, 104 of metre gauge, 80 of 30in., and 11 of 24in. gauge. All the lines which are actually in operation are of metre gauge, with the exception of 55 miles of standard gauge.

In the new Central Railway station at Lisbon, the tracks are provided with turntables operated by hydraulic capstans, one capstan serving four tables. Each turntable has six stanchions placed at equal distances apart around its circumference. The rope from the capstan is passed around the table as far as necessary and hooked to a stanchion and the other end given several turns on the capstan. When the latter is set in motion, and the strain comes on the rope, it is drawn against the stanchions, and the table rotated as far as necessary, even to a complete revolution.

A serious breakdown occurred on Sunday morning last on the Great Western main line. A heavily laden mineral train was proceeding towards Wolverhampton when a tire of a wheel of one of the front wagons broke. The wagon left the rails, as did also all the other wagons on the train. The permanent way and the rolling stock were considerably damaged, and the wagons and their contents were strewn about the up and down lines, but without any person being injured. Both lines were blocked for several hours. Since iron tires were disused accidents of this kind have been seldom.

In its new "class P" locomotives the Pennsylvania Company has tried a new method of fastening piston-rods into crossheads. An American contemporary says:—"The end of the piston-rod is turned down, but a collar is left on the very end of it. Over the part thus turned down a nut made in halves is fitted. The crosshead is tapped out for this nut and the latter screwed home until it locks the collar of the rod against the bottom of the bore of the crosshead. The nut is provided with a flange outside of the crosshead through which a pointed set screw is fitted, and this when forced against the face of the crosshead prevents any movement of the nut."
